If one hundred readers of the REPORTER would suggest a course of treatment for M.'s patient, I do not suppose that there would be any two that would recommend the same throughout; but M. might select out of these such as he thought appropriate to his patient's condition, and effect a cure. We select our treatment largely from the combined experience of others, varied according to our judgment to suit the different conditions of our patients; and the principal feature in a man's success in the treatment of disease is his ability in applying remedies suitable to remove the cause and counteract the destructive tendency of diseases. It may be that many of the readers of this valuable journal cannot avail themselves of very many medical writers on this special subject, hence I suggest that many replies to query No. 1 might prove of much interest to many readers, and result in much good to our suffering and hysterical patients.

If I were called upon to diagnose M.'s case, I should name the disease chronic metritis; but I would not treat the patient according to the name of the disease, but according to her condition. In this, as in all other local inflammations, the general health is affected differently; in fact, we will scarcely find two patients presenting the same symptoms; hence it will appear that the treatment should vary accordingly.

M.'s patient is anæmic, which probably is due to derangement of the digestive organs; if there is irritation I would proscribe all stimulants in the form of food or medicine, and give such remedies as have a tendency to allay irritation and promote digestion. Zinc ferri chlorid. will prove

useful as an astringent and tonic. Fluid ext. gentian, ergot, hydrastis can., ipecacuanha (in small doses), and the mineral acids, I have found to give best satisfaction in this condition. But there may be a condition of the digestive system quite opposite to that of irritation; there may be atony, the mucous membrane may be pallid, relaxed and flabby, denoting general torpidity; wherein I would recommend such remedies as have a tendency to stimulate the action of the organic nervous system, such as nux vomica, quinine, etc. The elixir of calisaya and strychnia and iron, will be found an agreeable and efficient tonic in this condition. Constipation is a very common complication, and to remedy it I have found nothing better than three drops of fl. ex. belladonna before going to bed. The effect is sometimes slow, but if continued, will prove sure.

The local treatment is of equal or more importance than the constitutional. M. informs us that there is a slightly retroverted uterus and enlarged os, and that there is leucorrhœa.

I would expose the os with a bivalve speculum, touch the ulcers with nitrate of silver, replace the uterus carefully with a sound, then fill the vagina with a tampon of absorbent cotton, previously well saturated with glycerole of tannin, one drachm to the ounce of glycerine—in a manner that tends to maintain the normal position of the uterus. The patient should be directed to remove the application after it has remained thirty-six hours, by means of a small tape that should be fastened to the uppermost part of the cotton. She will experience no inconvenience from its presence except a constant fluid discharge, which she will look for anxiously if she is previously informed that it is the effect desired.

If an antiseptic is indicated, five per cent. of carbolic acid added to the glycerine mixture will prove useful. This should be repeated every third or fourth day until the ulcers and mucous discharge disappear, and then at intervals of one, two, and three weeks, until a cure is effected, which will probably require from three months to a year; in some cases longer. If the leucorrhœa proceeds from the uterus, I would apply Monsel's solution to the uterine mucous membrane, by means of lint wound on the end of a probe or sound.

Where there are neither versions nor flexions, the patient can effectually apply the vaginal tampon herself, and will find it much more efficient and agreeable than injections. But I would not discard the injections altogether; when used alternately with the above treatment, they will be found very useful in many cases. As an injection, I have found the following as good as anything I have tried:

R. Fluid ext. hydrastis Cand.,	3 ij.
Zinc. sulph.,	gr. xx.
Morphia sulph.,	gr. x.
Acid carbolic,	ij.
Acacia, pulv.,	ssj.
Aqua,	3 ij.

M.

The consistency of this mixture is an advantage in retaining it in contact with the mucous membrane.

I have used suppositories of sulph. zinc., alum, etc., but my experience with them does not justify me in recommending their use. There are many

other remedies and appliances that may be equal or more beneficial than those mentioned. I have only mentioned those that have proved most beneficial in my hands. I hope to see in your columns better plans of treatment than the one I have suggested; yet I hope that what I have written will shed a ray of light in the mind of some one where there has been darkness.

Mt. Sterling, Ky.

J. H. MOORE, M. D.

Uterine Disease.

EDS. MED. AND SURG. REPORTER :—

The case described by "MEDICA" in your issue of February 23d, is a type of many which have come under my notice for some years past. The accident whilst driving may or may not have had something to do with her uterine trouble. I would suggest—

First. Discontinue *all* internal medication for at least thirty days. Let her diet be light and unstimulating, such as cracked wheat with good cream for breakfast, with cocoa, if she can digest that, or if not, an orange or two half an hour before the meal in lieu of the cocoa. For dinner, strong concentrated soup, varied daily, with such fruit as she may relish and easily digest. For supper, either weak tea or milk, with mush boiled, of corn or oatmeal, and stewed fruits, toast, bran-crackers, or soda-biscuits; at each meal. To this add gentle massage of the entire body both morning and evening, on rising and retiring, by a member of her family, who can be taught the method in one sitting if ordinarily intelligent. The doctor must now manage the rest. Apply daily a galvanic current of fifteen or twenty cells, as follows: the positive over the solar plexus; the negative on the genito-spinal centre. The current should be stable and uninterrupted; the duration half an hour. Morning is the best time for the application. General faradization succeeding the galvanism is also of value, but is not absolutely necessary. In two or three weeks this course will develop both appetite and strength, and at the end of a month the potassio-tartrate of iron, with Fowler's solution, is advisable.

As amenorrhoea is simply a symptom, it need not be directly treated; the probability is that her neurasthenic condition being relieved, menstruation will voluntarily recur. If it does not, then I venture to suggest that as there is no such thing as an emmenagogue *per se* except electricity, the application of static currents directly to the utero-ovarian system is indicated. The method I adopt is described in other places.* To the cervix might be applied, by painting it thoroughly outside and up to the os internum, the following, once or twice a week:

R.	Acid tannic,	
	Acid carbolie cryst.,	
	Iodine resublimat.,	
	Potassa iodidi,	aa ʒj.
	Glycerine,	f ʒ ij.
	Tr. iodini,	f ʒ ij.
M.	Sig.—Apply as directed.	

*What is Wrong with our Emmenagogues?" Therapeutic Gazette, November, 1882, p. 403.

MEDICAL AND SURGICAL REPORTER, November 28, 1874, case 3, p. 422.

Medical Bulletin, vol. iv., p. 88.

Second. Injections per vaginam are of little value in any case, as they act for a limited time, and are carelessly given as a rule. Suppositories are dirty, and the greasy adjuvant or vehicle destroys frequently any therapeutic value. Roll a long or short cotton tampon loosely, soak it in the selected astringent (properly diluted if strong or escharotic), and insert it at bedtime, withdrawing it by an attached string in the morning. It may, if necessary, be also used through the day. A napkin will prevent soiling the clothing, and the *whole effect* will be thus obtained *persistently* of any agent employed. This method I always employ; it is cleanly, simple, and thoroughly efficacious.

WM. R. D. BLACKWOOD, M. D.,

Neurologist and Electrician Presbyterian Hospital; Physician St. Mary's Hospital, Philadelphia.

No. 246 North Twentieth street.

NEWS AND MISCELLANY.

How Smallpox may be Spread.

The following incident that is recorded in the *British Medical Journal*, January 26, 1883, is interesting so far as it evidences the interest that England is taking in hygiene, and serves as a good example for us to follow:

"A newspaper vendor residing in Old Ford Road was summoned before Mr. Lushington, at the Thames Police Court, for sending out a large quantity of newspapers to his customers after he had been warned not to do so by the inspector of nuisances. The medical officer of health, at the hearing of the case, stated that, as the daughter of the defendant was suffering from smallpox in a room opening into the shop, and as the room-door was open, and the vendor came out of the room into the shop, he had no doubt the papers removed were liable to infection from the disease. The defendant was fined \$25 and costs, and was locked up in default. This is a very important decision, as considerable doubt has been expressed as to paper coming within the meaning of the section, and whether or not papers or books can convey infection. Many sanitarians doubt if letters sent by post, or books returned from smallpox patients, can convey infection; but as to the latter, there are cases on record to show that they can. Infection was, however, conveyed from this house into the adjoining parish of Hackney by the removal of a family residing in an upstairs room, one of whom was attacked with the disease fifteen days after taking up her new residence. This case shows the necessity for strictly forbidding children going to school from infected houses, as there was not, so far as could be ascertained, any personal communication between the sick and healthy."

International Medical College.

There is good prospect that the next International Medical Congress—which, as our readers may remember, will be held at Copenhagen, beginning August 10 next—will be a grand success.

Many valuable communications have been promised, and nearly four hundred non-Scandinavian colleagues have already announced their intention to attend. From France, amongst others, come Pasteur, Paul Bert, Ranvier, Charcot, Verneuil, Cornil, Hayem, Malassez, Chauveau, Ollier, Tripier, Lepin. From Italy—Bisozero, Mossa, Galgi, Peromoto, Novaro, Reymond, Giacomo, Baccelli, Tomasi-Crudeli. From Holland—Donders, Guye, Engelmann, Heinsius. From Germany—Virchow, Ludwig, Esmarch, Volkmann, His, Braune, Kronecker, Munk, Kühne, Heidenhain, Vogt, Bernstein, Grohe. The most eminent medical men of Sweden and Norway have become members of the various committees of organization.

Anti-vivisection in Germany.

In Germany, as elsewhere, the false sentimentality which would obstruct science by preventing vivisection has been active. The official, however, to whom the matter was referred has had the good sense to permit science to draw its own boundaries, and to say how far research by experiment is necessary. Applying to one celebrated professor of physiology for information, the gentleman gave his answer in a sufficiently concise and striking manner. Taking up the last edition of Hermann's "Hand-book of Physiology," he struck his pen through all those parts of the work that were based on experimental research or in any way indebted to it. The result was that not more than one-fourth of the book remained uninjured! The lesson was not taught in vain, and the important result given above may be due in great measure to the great aptitude for teaching thus shown by the distinguished professor.

Healing by Faith.

The *Lancet* tells us that a remarkable instance of this kind is reported in England, where a girl, who had been suffering from paralysis of the neck for twenty months, and unable to raise her head from the pillow, was suddenly healed, sat up in bed without any assistance, and has since been dressed and able to walk about. This instantaneous effect was produced during the prayers of some Blue-ribbon friends, and has created a sensation among the lovers of the marvellous in the district where the patient resides. It is difficult to convince the unlearned that supernatural agencies are not necessary to bring about results of this character, and that more wonderful instances of the influence of a superior will, or appeals to the senses of highly excitable or sensitive invalids, have been recorded as testimony of scientific laws now well recognized and known.

To Cure Diseased Plants.

M. Villermoz, a celebrated French horticulturist, recommends the watering of diseased plants with warm water, after having previously turned up the earth, without touching the roots. The water that escapes from the bottom of the flower-pot is at first clear, but it afterwards becomes lightly brown and yields an acid reaction, to which M. Villermoz attributes the diseased condition of plants, the hot water acting not only as a

stimulant, but possessing the power of eliminating the acid substances with which the soil becomes impregnated. By this treatment M. Villermoz has seen almost completely withered plants restored to life in a short time, and he thinks that the same may be applied to plants in the open air.

Extraction of Teeth without Pain.

At the Paris Société de Biologie M. Paul Bert introduced to his colleagues a method recently discovered by a Geneva dentist for extraction of teeth without pain. The method is very simple, and can be used by the most ignorant; it consists of a piece of India rubber through which a hole has been made to receive the crown of the tooth, pressed down tightly in the gums and left *in situ*. By the heat of the mouth the elastic contracts, and by that operation the tooth is loosened in its alveoli, and finally is lifted completely out of its bed to the relief of the patient. It takes four or five days to effect its purpose. Any improvised piece of caoutchouc would do.

Prize Essay on Criminal Anthropology.

La Rivista di Discipline Carcerarie offers a prize of 2,000 lire (\$400) for the best essay "to exhibit the progress made in the present century (in Italy and elsewhere) in the study of criminal anthropology, and the theories upheld by the most competent writers; to examine the facts and statistical figures adduced in support of such theories, and to compare them or to combat them with other facts and with other statistics." The prize is open to all comers. The essays must be written either in French or in Italian, and must be sent to the *Direzione della Rivista di Discipline Carcerarie* not later than December 31, 1884.

The Hygiene of Children.

As affording us a good example, we are pleased to note that with a view to the discussion of questions of school hygiene, periods of study, gymnastic training, prevention of disease, and allied questions connected with growing boys and girls, it is proposed in England to form a society of medical officers of public, charitable, and general schools. At the meeting of this society papers on these important questions would be read and discussed, and the experience gained in the various institutions collected for the general good.

Items.

—It gives an idea how London grows that in a single week in February the births exceeded the deaths by 1,215. The death rate that week was only 19.5 per 1,000.

—Carl Jensen, of Philadelphia, has instituted suits to recover damages from manufacturers infringing his patent process for manufacturing "Crystal Pepsin."

—A singular accident happened lately at a mill in Nashville, Tenn. A workman was thrown towards a circular saw, and, thinking he would strike it, died from fright. When picked up he was dead, but there was no sign of a bruise on his body.

—London journals report the deaths of two medical men from suicide. One was discouraged at the difficulties in getting practice, and the other had been accused of procuring abortion.

—Dr. Price, the aged Welsh Druid who recently attempted to dispose of the body of his infant child by burning it, has been tried and acquitted. The justice, in addressing the jury, said he had been unable to find any law forbidding cremation.

—Prince Ferdinand, of Bavaria, brother-in-law of the Duke of Genoa, having published a work with the title "The Anatomy of the Tongue, and Studies in Comparative Anatomy," has received from the University of Munich the honorary degree of Doctor of Medicine.

—In April next, Professor Frerichs will have completed twenty-five years of service as Director of the Medical Clinic in Berlin. It is intended to celebrate the occasion by a public festival; and a committee, consisting of Professors Bardeleben, Laner, Leyden, and others has been formed to carry out the object. A marble bust of Frerichs will be unveiled on the occasion.

—Vomacka gives the following directions for the preparation of a substitute for blue ointment, which also keeps better: One part of soft and perfectly neutral potash soap is mixed with a little glycerine in a glass mortar, and one part of mercury is added with constant trituration. When no globules of mercury are any longer visible, add two parts more of potash soap to make four parts. It may be scented with lavender or other essential oil.

OBITUARY NOTICES.

LUNSFORD P. YANDELL.

Dr. Lunsford P. Yandell died suddenly March 12th, from Neuralgia of the heart. Dr. Yandell was, at the time of his death, the editor of the *Louisville Medical News*, and was a physician of extensive reputation both as a contributor to the literature of the profession and as a successful and active practitioner. He was 47 years of age.

GEORGE ENGELMANN.

At St. Louis, March 4th, Dr. George Engelmann. Dr. Engelmann was born at Frankfort-on-the-Main, Germany, February 2, 1809, and was consequently, at his death, seventy-five years and two days of age. His university education was acquired at the universities of Berlin, Heidelberg, and Wurzburg. In 1832 he came to the United States, and three years after setting foot upon the eastern shore of the country, he found himself in St. Louis, in the heart of the country. There he began the practice of medicine, and continued the study of it and other sciences. In the year 1839 was founded the Western Academy of Science, Dr. Engelmann being one of the organizers. For a number of years the society flourished, and then died. He was one of the originators of the St. Louis Medical Society, and was for some time the president of that body. In 1856 the St. Louis Academy of Science was organized, and he was one of the founders, and for many years held the honorable position of president. His son is a well known gynecologist.

QUERIES AND REPLIES.

EDS. MED. AND SURG. REP.—

On reading the few lines on Dr. Rezin Thompson in the *REPORTER* of March 8, I will add my mite—not biographical, but professional, for of the former I know nothing.

Although it has been several years ago, I remember well his strong advocacy of oil of sassafras in the treatment of zymotic diseases, and that his theory of its therapy was based upon his idea that all continued fevers were caused by the admission of germs into the system, and because he found the oil of sassafras was a powerful insecticide. I have heard physicians who were personally and professionally acquainted with him say he was wonderfully successful in treating typhoid fever.

I cannot call to memory now his formula for making his fever syrup, but do remember that oil of sassafras and the expressed juice of the green peach leaves were two of the most important, in his estimation. It is my impression rhubarb and carb. soda were the other ingredients.

I have little doubt that Prof. W. L. Nichol, of the Medical Department of Vanderbilt University, Nashville, can give you further information, and I hope he will. Dr. Thompson was a very eccentric man, but a fine physician, a liberal and independent thinker. His therapy was based upon the germ theory of disease, and most likely he was the first to publish such views. Respectfully,

S. W. CALDWELL, M. D.

Trenton, Tenn.

Asthma.

EDS. MED. AND SURG. REP.—

I noticed in a late number of the *REPORTER* a request for the treatment of asthma which had been found most satisfactory. In the course of a long practice, I have treated several cases of asthma, and have derived benefit from iod. potass., which, indeed, is the medicine in which I placed most confidence until employing *grindelia robusta*; this I have used in but two cases, but with benefit in both. Indeed, in the last case in which I have used it (formerly treated by iod. potass.), the patient is loud in his praises of the remedy, which he declares has done him more good than anything else he has ever taken.

Wishing to satisfy myself as to its effects, I gave it uncombined, but think it quite possible that there might be an advantage in combining other medicines with it, according to the original recommendation of Dr. Gibbons, of California.

A lady, a former resident of our county, is so affected with asthma when in this State that she resides most of the time in Colorado, where she finds immunity from her troublesome complaint.

I might add that believing in the positive treatment of all diseases that require anything more than "good nursing," I have given the *grindelia* in full doses.

COMMUNICATIONS.

THE UNKNOWN FACTOR IN THE EQUATION OF THE NERVOUS SYSTEM.

BY J. M'F. GASTON, M. D.,
Of Atlanta, Georgia.

(Continued from page 361.)

It is not supposed that the use of medicines by the mouth can be entirely substituted by other modes of introducing them into the system. In all cases that may be appropriate for propagating the best effect of medicinal agents through the stomach, of course this channel should be adopted. Yet there are numerous instances in which embarrassment is presented in the repugnance to swallowing medicines, or in the inability to retain them; while there are many cases in which medication through other channels is attended with more satisfactory results in the treatment of the disease. The hypodermic method is better adapted generally to acute diseases, and yet should not be confined exclusively to this class of derangements, as there are chronic cases that require this kind of treatment.

The advantages of medicated injections upon the organism are manifested, not only when made into the areolar and cellular tissues, but also when passed into the substance of glands and tumors, into mucous and serous cavities, and into the excavations of various abscesses. This depends upon a peripheral development of nerve energy, co-existent with the general distribution of the capillaries and the minute nerve fibrils to the cutaneous surface, and to the serous and mucous membrane, as likewise to the reticulated struc-

ture and cellular tissue, that become exposed in abscesses. The impressions upon these several parts are, to a great extent, independent of the brain and spinal marrow, and *yet are extended by a connecting link of the ganglionic nerves in such a way as to reflect a vital influence of the remedial agent back upon the respective structures.* There is abundant evidence of the close relations of the great nerve-centres with the cutaneous and other superficial structures, yet it is not known what is the exact line of communication from one to the other, nor through what channel the centripetal and centrifugal forces operate in propagating the impressions made upon the different classes of tissues. A precise understanding of the distinct relation of the nerve fibres to the capillaries, and their joint influence upon the nerve centres, and through them upon the various internal organs, is a desideratum for experimental physiology.

The subcutaneous areolar tissue is so intimately connected with the internal parts by the correlation of the capillaries and the nerve fibrils, as to afford a most important medium for the application of remedies. Their effects are manifested more speedily either by absorption or by direct action upon the nerves than is practicable through the stomach.

In the true language of Dr. H. C. Wood, "the subcutaneous tissue affords the most rapid route to the central organs;" and this line of approach to the citadel of life, requires more thorough research on the part of scientific men.

An explanation of "the action of medicine on the cure of diseases," must be sought in a primary impression through the capillaries upon the minute ramifications of the nerves, which is ex-

tended to the nerve-centres, and thence propagated by the joint influence of the ganglionic and spinal nerves to the whole vital organism. The immediate transmission of the venomous emanation from the bites of poisonous snakes and insects, cannot depend upon the comparatively slow process of passing through the ordinary route of the circulation, but results from the entrance of the poison through the network of capillaries and nerve fibrils, being transmitted from the former to the latter, and thence by the nerves to the nerve-centres, with the convergent derangements and disturbances of the animal economy. It may be that the antidotal influence of hartshorn, or other corrective, could be efficaciously applied through the same channel, and if an immediate resort to the subcutaneous syringe could neutralize the poison or its effect, it should be hailed as a grand advance in therapeutics. There is a peculiar result from the curari, that unlike the venom of snakes, does not occasion local inflammation when inserted into a wound, but appears to act exclusively on the nervous system. It manifests its effects in arresting the action of the lungs sooner than the pulsations of the heart, and hence creates a strong presumption against the operation of the poison by means of the general circulation, notwithstanding that it has access to the nerves through the medium of the blood in the capillaries. The influence of this powerful agent is so limited to the nervous system, that when the lungs cease to act, while the heart continues to beat, respiration may be maintained artificially until the otherwise fatal depression passes and restoration ensues. In the course of a few hours, the poison is dissipated and eliminated, and leaves the system in a condition to recuperate its natural powers by a return of nervous energy.

It may be deduced from the facts already known, that independent of any direct operation upon the nerves, the influence of traumatic poison is developed through the circulation of the blood upon the ganglionic system of nerves, and as a consequence, the implication of the pneumogastric nerve, which controls to a large extent the action of the lungs. Yet, this does not preclude the recognition of a primary and immediate action through the capillaries upon the correlated fibrils of the nerves, and the transmission thence of this influence; and the route followed in the introduction, progress, and elimination of such agents, requires to be more closely defined, indicating the source of the disorder to the animal economy. Outside of the residual influence exerted by external applications, we may note the

operation of accidental impressions from various sources upon the human system.

The transmission of cutaneous modifications to the internal organs, becomes in many instances a source of disorder to the animal economy. The contact of cold and moisture with limited portions of the surface of the body in an irregular or partial manner, interrupts the nerve power in such parts, and thereby interferes with the proper equilibrium of the circulation in a way to impair the dependent organism. Currents of air acting suddenly and locally on the surface of the chest, frequently induce pneumonia or pleurisy.

The liver becomes deranged by undue exposure to the sun and night air, from the influence of the alternations of temperature upon the skin.

The intestines and bladder are often affected from dampness of the feet and vicissitudes of the weather, operating upon the surface.

Rheumatism and neuralgia are the ordinary results of sudden atmospheric changes; and though the person may be exposed generally to the deleterious impression, certain parts are attacked, owing to a predisposition to such derangements in their tissues.

The exact line of operation in any of these impressions, by which the effect is produced upon the vital functions, cannot be clearly traced. Yet there are sufficient data upon which to base a very plausible solution of all the varied manifestations of this relation of the outer and inner parts in health and disease.

The medical profession are familiar with many facts that go to sustain the pervading modification of the organism through this connecting link of nerves, and the special nature of the cause is propagated in a peculiar way for the development of specific diseases in the varied structures of the body.

The absorption of any virus into the system, by contact with a delicate mucous surface, or by its introduction beneath the cuticle, develops subsequently the specific constitutional effects of the special contamination. As an instance, the syphilitic virus comes in contact with the delicate tissues of either sex, and its immediate and direct influence upon the part is not perceptible for the time being, but in the course of a definite period of incubation, it causes an ulcer upon the surface. Again, from this point, in the course of a variable period, there is transmitted throughout the organization a peculiar and distinct disorder, which indicates that this poison has been operating gradually, but surely, through some definite channel, to bring about this effect.

Here is a point for study, and presents some of the obscure points of my theory more distinctly than is shown by any other phase of the reciprocal relations between the surface and the interior structure of the body, with their dependencies.

We observe a peculiar process in the termination of the incubatory state by the primary ulcer of syphilis, and we further note its advances in the ultimate development of the secondary phenomena of this disease. This exhibits a class of results quite different from those previously adverted to, and experience affords other convincing proofs of the extraordinary vital link by which distant parts are associated.

In the simple operation of vaccination and its consequences, we have an illustration of the same principle. As in the case of the virus of syphilis, the vaccine lymph is brought into contact with the delicate tissue beneath the cuticle, and then appears to remain dormant for a definite period, when it is found to have been transmitted through a distinct channel to the general system. At the expiration of eight days, more or less, it develops a characteristic pustule at the point of introduction, accompanied by a corresponding constitutional excitement. It is not considered that the retention of the vaccine lymph for this period, causes a mere local influence upon the tissues. Those who have any claims to pathological knowledge, view this as simply a *punctum salicus*, from which a special disorder is propagated to the general system.

The pustular eruption at the point of introduction is only an evidence of its complete development, or a local manifestation of a constitutional disease, which by its pervading character exempts the subject from the access of variola in the future.

In this connection, attention may be drawn to the very extraordinary history of the varying conditions that characterize the latent period of the germ or virus of hydrophobia. An individual being bitten by a rabid dog, and no steps being taken to intercept the absorption of the poison, it should naturally be inferred that the consequent disturbance should present itself within some definite period. Yet, by some unaccountable modification of the dynamic element that operates in the propagation of poisons to the general system, it occurs that no calculation can be made as to the lapse of time in which the disorder may appear.

The condition consequent to the contamination is not localized, as it is notorious that any delay in excising the part bitten or in neutralizing the

effect on the tissues, is unavailing for the arrest of the evil.

The malady must, therefore, from the outset be in operation, and is gradually propagating its influence, according to its quality, through the organization.

There is positive evidence that an impression made through the areolar tissue, or even upon the delicate mucous membrane, finds ready access to the subcutaneous net-work of capillaries and nerve fibrils, leaving its effect on them.

This influence is transmitted in a definite and uniform manner, through a nervous channel to the central parts of the organization, so as to operate through the ganglionic system in developing the consequences that qualify the agent employed.

It may yet be ascertained that all these striking developments of structural disorder arise from some molecular change, that is to be corrected upon a large generalization of therapeutics.

It is incumbent upon the pathologist to afford a satisfactory exhibition of the mode in which the efficient cause of derangement brings about the consequent alterations in the functions of the various organs, so that we may be enabled to proceed understandingly in arresting the disorder.

It devolves also upon the physiologist to point out the modifications that may be impressed upon the nervous system, consistently with the normal tone of the healthy organism, and through what agencies and by what routes effects are produced. The propagation of nerve power from the spinal column, as exhibited in the voluntary movements of different parts, and the reception of impressions from without or within the body, depends upon the anterior and posterior branches of the nerves, which are classified as motory and sensory, according to their respective capacities. This important distinction in regard to the attributes of these two sets of nervous trunks is due to the investigations of Magendie, though it has been claimed for Sir Charles Bell up to a very recent period.

The relations of the nerve fibres in the different segments of the spinal cord, and their association and decussation in the medulla oblongata, have been demonstrated by Charcot in a satisfactory manner. They supply the requisites for the nice and varied conditions of action and re-action from the many impressions upon the sensory nerves. The most recent researches have assigned very complicated functions to the medulla oblongata; and these additions to our knowledge enable us to interpret more accurately the variations in the different regions of the cord, and in

the different columns, as modified by transmissions from the afferent and efferent nerves.

Those manifestations and exhibitions that are associated with the spinal cord in its reflex capacity, are not in any way identified with the phenomena which are developed by the reciprocal relations of the capillary plexus with the great sympathetic nerve. The sensations, with the voluntary and reflex movements, are not associated in the demonstration of these mutual dependents. It is to the organic system of nerves, and the nerve fibres intermingled with the capillaries, that we must look for an explanation of the effect of remedies, poisons, and other varied agencies, which operate through peripheral impressions upon the body.

The general division of the nerves into the cerebro-spinal and ganglionic systems, presents a satisfactory solution of most points connected with the performance of the animal and organic functions. A separate, if not an independent action on the part of the great sympathetic, admits of nutrition, secretion, and excretion, with the special acts of respiration and defecation, while the cerebro-spinal influence is interrupted by paralysis or other agencies of a temporary character. Yet the key to the vital casket needs to be given to the physician. An intelligent explanation of the sympathetic relations of the nerve fibrils and the capillaries, with the normal and systematic performance of the functions of the various parts of the human organization, on the part of the physiologist, will conduce greatly to a better understanding of the derangement of the vital operations by the pathologist. We need precise information in regard to the workings of these two divisions of minute structures, and I have sought in vain for any satisfactory solution of the recognized influence of the nerve-fibrils and the capillaries upon the vital functions.

(To be Continued.)

AN UNOBJECTIONABLE FORM FOR THE ADMINISTRATION OF MEDICINES.

BY M. S. FRENCH, M. D.,
Of Philadelphia.

Of all the various forms in which medicine is prescribed, there is none so well suited for the administration of drugs possessing a poisonous influence, unpleasant odor, or taste, as the manufactured pill form.

The advantages derived from prescribing remedies in this form are so apparent, that it was a matter of surprise to learn that their use was not

more general. It is on this account that I present this short article, hoping that it may lead to more extensive use and appreciation of this valuable method of prescribing.

Manufactured pills will become more popular with physicians, as their value and advantages are recognized. They are so beautiful in appearance, so accurately compounded, so quickly dispensed, reducing the danger of making a mistake, on the part of the physician or druggist, to an almost impossibility.

They also enable the physician to carry with him, in a small and compact form, ready for administration, all the remedies that might be needed in emergencies, and night practice.

To the physician engaged in country practice, where his patients are at a distance from a drug-store, they become of especial value.

In that class of pharmaceutical preparations which exhibits medicines in an elegant and palatable form, without the sacrifice of quality, uniformity or accuracy, American pharmacists have been doing excellent work, the result being that most of the objectionable features which formerly pertained to manufactured pills have been removed, being now produced in such a perfect and attractive form, that the most fastidious patient can find no objection to urge against their use.

There is little doubt but that much of the popularity of Hahnemann's system of cure, based upon the maxim *similia similibus curantur*, is due, not to the truth of the law, but to the preference for the tiny, tasteless and attractive pellets; and the sooner the medical profession recognizes this, the quicker will the public see that, aside from pleasant doses, there is nothing but fallacy and error in homeopathy.

There are some drugs used in practice that cannot be administered in pill form, and there are instances where solutions are preferable. Such is the case in treating the various types of fevers, and where tonics are employed; but in the greater number of cases, the object desired is a continued influence, rather than an immediate impression upon the system, and for the accomplishment of this end pills are best suited.

In an article of this nature, it is not necessary or possible to dwell upon all the conditions to which the administration of remedies in the manufactured pill form are applicable, but to detail a few of the more frequent diseases, and specify instances where they have been used with success, during the past six or seven years.

The physician engaged in city practice sees no departures from health so frequently, as those as-

sociated with the digestion and assimilation of food. A majority of the patients presenting themselves for treatment, suffer from either a simple dyspepsia or some one of its many manifestations. The life led by people massed together in large cities is such an artificial one, the inhabitants being so subjected to the enervating influences surrounding them, that the indiscretions of diet, mode of living, anxieties, and the continual struggle for existence, become active factors in producing the large number of dyspeptic cases.

There are certain conditions that cannot be relieved by dietetic and hygienic treatment alone, but require the use of drugs, which should be given in the most pleasant and unobjectionable form; as there is no class of patients so prone to find fault with their medicines, being best suited by doses that are attractive, tasteless and not bulky.

It will not be a digression to dwell upon the treatment of this common affection, as it will enable me to mention more particularly the remedies suited for administration in the form under consideration.

The power of digestion being depressed, special aids to that function will be found in pepsin or alkalies; the anæmic condition may require iron, quinine or strychnia. Where remedies are needed, the action of which must be sedative, good results may be obtained from bismuth, opium, belladonna, arsenic or silver.

A very useful pill is that of aloin (gr. $\frac{1}{8}$) and strychnia (gr. $\frac{1}{16}$) given at bedtime; this will produce a mild, thorough, laxative effect, unloading the stomach and intestines, removing the fetid breath, the furred coating upon the tongue, and the cerebral congestion.

An error liable to be committed is the administration of cathartics of too active a nature; they are rarely called for, do little good, and might possibly do evil. Mild laxatives only are required, and care should be exercised as to their selection and frequency.

Formerly it was my custom to use pepsin and pancreatine more than at present, as recent investigation has led me to believe that as much benefit can be derived from the former agent alone, as when given in combination with the latter. Pancreatine has been shown to be itself digested by pepsin, so that its chance of getting through the stomach to the duodenum, where it normally exerts its function, is very slight, while when combined with pepsin, it must be digested as soon as the mixture becomes warm enough, in or out of the stomach, to carry on the process. Yet we see

many preparations of which the chief virtue is supposed to be that they contain *all* the digestive principles. These can be active only so far as they contain pepsin, and have no advantage over the simple drug.

It has also been shown that certain substances combined with pepsin in solution, render it inert. Alcohol is one, and even in moderation diminishes its action, while, in any quantity, the activity of pepsin is totally prevented. This is a point often lost sight of, and serves as a hint concerning the use of liquors at meals, by dyspeptics.

Pepsin and bismuth are frequently combined when treating dyspepsia, and should always be administered in pill form, owing to the difficulty of keeping both agents together in a permanent solution, one requiring a somewhat acid menstruum, the other a neutral or an alkaline one. Nothing is more common than to see elixirs of pepsin, bismuth and strychnia, which darken, harden, and shrink the albumen placed in them. Liquid preparations are theoretically, if not practically, inconsistent, and will generally be found to be unsatisfactory.

In treating that form of dyspepsia met with in malarious districts and in persons who have passed the autumn months in the country, much good can be obtained from quinine, or a combination of quinine, iron and arsenious acid, given after meals and for a length of time. When using quinine the pill form is the best that can be resorted to, the soluble-coated pill possessing many advantages over the solutions, capsules or wafers. In an article upon quinine, published about four years ago, I called attention to the ready solubility of the bi-sulphate and urged its use, being the most soluble of the quinine salts used in medicine. On this account it is more active and better calculated for administration in pill form than the sulphate; but it should be borne in mind that as the bi-sulphate of quinine contains a smaller proportion of the pure alkaloid, the amount being only about 60 per cent., the dose should be one-fourth greater than that of the sulphate, in order to represent the same amount of alkaloid.

Iron is a most valuable remedy in the treatment of dyspepsia, but furnishes best results when given toward the termination of a course of treatment.

Active business men, brain-workers, and those who are subjected to much mental anxiety or overwork, frequently suffer from what is termed "nervous indigestion." To meet this condition we possess a valuable remedy in phosphorus, which should be given in small doses, immediately after meals.

The best form of administering phosphorus is that afforded by the manufactured pill, which possesses many advantages over those made to order in the prescription room. A pill of this kind is exceedingly difficult to make, requiring especial care and skill. The phosphorus should be incorporated with the various ingredients, while in solution, so as to effect a thorough and uniform diffusion; they should also always be coated, in order to prevent oxidation. I have made some interesting experiments with phosphorus pills manufactured by Schieffelin, of New York, proving that their coating entirely protected the enclosed mass. A pill that had been manufactured a year ago was cut open, and the mass found to be as soft as though made but a few days. Another pill, of the same manufacturer, made eight years ago, was found to be but little harder. Upon placing two of the latter pills in a small quantity of water, the coating was quickly dissolved, the mass broken up, and when placed in in a dark room the vial was plainly perceived, owing to the unaltered luminous property of the phosphorus. This simple experiment goes to show that if properly made and coated, a manufactured pill does not become affected by age, nor do the various ingredients become so altered that they lose their medicinal properties. Experience has shown that such pills may be kept for years, even in a very warm climate, and still produce prompt and active effects when administered.

In treating the secondary forms of syphilis, the plan recommended by Dr. Keys, "of administering mercurials in granules," possesses many advantages over the older method of prescribing the same substance in solution. Intestinal irritation seems to be later and less painful in its manifestations, it is an easier matter to regulate the quantity given when pursuing the "tonic treatment," and the granular form is the most convenient and portable for the patient. Certain cases will be encountered where the symptoms are so pressing that there is not time to get the patient quietly under the influence of the drug, when administered in granules, but fortunately such are not frequent, and can be met by resorting to the older methods until the urgent symptoms abate. The obstinate lesions occurring in the mouth are most successfully treated with granules, the patient being told to allow the little pill to slowly dissolve upon the tongue, thus obtaining the effect of a solution of corrosive sublimate upon the patches, while at the same time the general treatment is pursued.

In a case where the mucous patches in the mouth

were very numerous and troublesome, no impression could be made upon them until the plan mentioned was tried, when they disappeared in a short time.

While pursuing the hyoscyamine treatment upon a patient afflicted with mental disease, the manufactured pills were of great advantage, as there was no doubt as to accuracy of dose, and they were easy to administer.

In a recent conversation with one of the leading alienists of this city, I was informed that he was using pills of this form upon several cases, considering them preferable to the hypodermic method.

When prescribing a medicine so powerful in its influence that doses of from $\frac{1}{200}$ to $\frac{1}{5}$ of a grain are desired, it is almost impossible to obtain the exact amount in each pill, unless a large number are prepared at one time and great care exercised in the manipulation of the mass. With drugs like arsenious acid, aconitia, aloin, atropia, codeia, digitalin, hyoscyamine, morphia, phosphorus, strychnia, and the more powerful mercurials, accuracy of dose and the decreased possibility of a careless mistake, are points in favor of the manufactured pill; while with such remedies as asafoetida, quinia, and others possessing a very unpleasant taste, the coating removes the objection to their use, which patients so frequently make.

Little children who struggled and had to be forced to take quinine when prescribed in solution, powders or uncoated pills, will take the drug without objecting, when given in a coated pill.

In this article it has been my intention to point out a few of the advantages possessed by manufactured pills, over those prepared in the old and ordinary manner, and to speak of a few cases in my own practice, where the results from their use have been satisfactory. During the past seven years, the soluble-coated pills made by Schieffelin & Co., of New York, have been the ones prescribed, and I do not hesitate to recommend them to the profession.

The "coating" of pills is a subject of much importance and of especial interest to physicians.

In a future article I shall bring to their notice some facts, to add to those published a number of years ago.

1423 Walnut Street.

—M. Renzi has contributed a paper on pulmonary syphilis to the *France Médicale*, in which stress is laid on the absence of bacilli in the sputa of such cases.

A FURTHER NOTE ON THE SPECIFIC TREATMENT OF ENTERIC FEVER.

BY JAMES C. WILSON, M. D.,

Physician to the Jefferson Medical College Hospital, and to the Philadelphia Hospital.

Read before the College of Physicians, of Philadelphia.

A year ago I read before the College a brief paper "On the Management of Enteric Fever according to a Plan Based upon the So-called Specific Treatment." That communication, which will be found in the sixth volume of the third series of the *Transactions*, beginning on page 221, was the outcome of the clinical study of a very limited series of cases in which the plan referred to had been fully carried out. The object of the present communication is to lay before you the results of the plan as employed during another year in the management of a second series of cases.

Before presenting to your attention the facts relating to this second series of cases, permit me to state that the plan of treatment consists in a close adherence to the so-called rational or expectant method of treatment in all its details, plus the systematic use of purgative doses of calomel in the early days of the attack, and of iodine and carboic acid throughout its whole course. These drugs are administered chiefly with the intention of realizing their effects in diminishing the activity of the supposed specific cause of the disease and the treatment is therefore properly designated a specific treatment, in contradistinction to the rational or expectant treatment on the one hand and to all forms of symptomatic treatment on the other.

The first series of cases numbered sixteen, of which all recovered.

The second series, treated during the year 1883, by a curious coincidence, also numbered sixteen, of which two died.

Of these, seven were severe, the temperature reaching or exceeding 104° F. (40° C.)

Of these seven severe cases, the two which terminated fatally were colored men, admitted to the wards of the Philadelphia Hospital late in the attack and in a state of profound stupor. One, aged twenty-seven years, died on the seventh day after admission; the other, aged forty-seven years, on the twenty-first day. The latter passed albuminous urine, and presented after death the lesions of interstitial nephritis in addition to those of enteric fever.

Two non-fatal cases were attended by profuse and repeated intestinal hemorrhage in the third week. One of these, a man aged twenty, had,

during convalescence, necrosis of the mastoid process of the right temporal bone. One case of great severity occurred in a man aged sixty-two years, whose convalescence was, however, rapid and without sequels.

No instance of relapse was observed.

The characteristic eruption was present in all the severe cases. It was not discovered in four of the mild cases.

The average duration of the five severe cases in which recovery took place was about thirty-two days; that of the nine mild or medium cases was about twenty-four days.

Of the whole number, six were treated in hospital and ten in private practice.

It is worthy of note that the convalescence in these cases was rapid, as a rule, without complication, and that no instance of relapse occurred. An analysis of the combined series shows as a result of this treatment in my hands thirty-two cases, sixteen treated in hospital, sixteen in private practice, with two deaths (cases admitted to hospital in profound stupor). The death-rate is, therefore 6.25 per cent. I refrain from citing, for comparison, the familiar statistics of the death-rate of enteric fever. We have come to regard it as ranging from 15 to 20 per cent., with a more favorable showing in private than in hospital practice. But Welch, from the statistics of the medical service of the British army, has recently shown it to exceed 33.3 per cent., and Dr. Francis Delafield, in an important statistical paper on this fever as it occurs in New York (see *Medical News*, November 24, 1883), has shown that the death-rate in hospital cases, though varying in different years, ranges between 20 per cent. as the lowest, and 30 per cent. as the highest limit.

HOSPITAL REPORTS.

A CLINICAL LECTURE DELIVERED IN THE HOTEL DIEU, PARIS, FRANCE.

BY DR. F. RAYMOND,

Fellow of the Society of Medicine, Physician to the Hôpital des Incurables.*

1. Acute Meningitis in the Course of Typhoid Fever. 2. Tubercular Meningitis in an Adult.

GENTLEMEN: The last few days we have observed together two patients who have succumbed to meningeal affections. One of them has had acute meningitis with rapid march in the course of typhoid fever. The other has died in consequence of tuberculous meningitis; this patient was a woman, aged 45, and the diagnosis of her

* Translated for the REPORTER by E. P. Hurd, M. D.

affection presented many difficulties, as you well remember. It has occurred to me that it would be interesting to review in detail these two cases.

1. The 16th of August, there entered our hospital, Ward St. Christopher, No. 6, a man 26 years old, painter by occupation. At the morning visit August 17th, the patient appeared prostrated, depressed, and in a partial stupor. The pale complexion, the flushed cheeks, the injected conjunctivæ, the burning hot skin, indicated at once that he was suffering from an intense fever, and in fact the thermometer gave an axillary temperature of 103° F. The pulse was weak and rapid (120 a minute), and manifestly dicrotous. When questioned, the patient responded willingly and with precision. He complained particularly of a violent headache, seated principally in the frontal region, and of tinnitus aurium. He also complained of pain in the back of his neck, in the region of the nucha; this pain was dull, continuous, and was increased by sitting up, which also caused vertigo and marked pallor of the countenance. The appetite was gone, there was intense thirst; the tongue, covered with a thick white coat, was dry at the tip and borders, which were of a lively red color, and appeared devoid of epithelium. The patient was much constipated, the bowels did not move without purgatives or injections.

The abdomen, somewhat tympanitic, was painful to pressure over the right iliac fossa. Pressure elicited no gurgling sounds. There were several lenticular rose-spots on the belly and back.

Percussion showed the spleen to be much augmented in volume. The nasal fossæ were dry, the voice was slightly hoarse; there was, however, no catarrhal angina.

Percussion of the thorax revealed nothing in particular; there were here and there a few snoring and sibilant rales, especially at the bases. Heart beats weak and precipitate. Urine, high-colored, acid, and albuminous. There seemed to be no marked predominance of morbid manifestations on the part of any of the viscera or the nervous system.

On interrogating the patient, we learned that previously to this sickness he had enjoyed good health. He came to Paris two years ago, pursuing his occupation till within about ten days, when, without any appreciable cause, he felt his strength leave him. He could not walk without vertigo; there was ringing in the ears; he slept poorly during the night; had startings in his sleep and frightful nightmares. At length he lost his appetite, and not being able longer to sit up, he decided to enter the hospital. Never had nose bleed; bowels always constipated. The diagnosis in this case was easy from the very first. The disease dated back in fact eight or ten days. We could therefore at once exclude all the eruptive fevers, which, as you know, during their prodromic period often manifest a clinical tableau which resembles the initial period of typhoid fever. Besides, on taking into consideration the cephalalgia, the lenticular spots, the meteorism, the augmentation of the volume of the spleen, the stupor, the insomnia, the state of general prostration, the march of the disease, there seemed to be warrant, notwithstanding the absence of diarrhoea and constipation (you have often seen in my service patients affected with typhoid fever, and who

were constipated—this has been the case in several epidemics), there seemed, I say, to be warrant for the diagnosis which we made, of typhoid fever; all the symptoms of the fever were in fact perfectly regular, if I may thus express myself. There was no predominance of symptoms on the part of the lungs, nervous system, or other organs, suggesting broncho-pneumonia, meningitis, etc. The prognosis, with such reserves as belong to every case of typhoid fever which has reached its eighth or ninth day, was quite favorable.

The 16th of August, the day of his entrance into the hospital, I put him on the following treatment: wine and water for drink; meat broth for nourishment; 30 grains of salicylate of magnesia every two hours, till a drachm and a half was taken; this to be the daily allowance of the medicine. You know, gentlemen, that the parasitic theory of infectious diseases is making a great many converts every day, and by reason of the new inclusion of typhoid fever in the category of germ diseases, there is a great therapeutic movement in favor of the antiseptic medication. You know the results furnished by the carbolic treatment and the treatment by salicylate of soda. One of the objections, and one well founded in my estimation, against these various medicinal agents—given with antiseptic intent—is the impossibility of making them reach the last portions of the intestines, where are habitually seated the lesions of typhoid fever.

Professor Vulpian has asked if it might not be possible to have recourse to other medicaments equally antiseptic, and capable, not being immediately absorbed, of having a local effect on the lower portions of the alimentary canal. It is in accordance with this view that I employ salicylate of magnesia, and I have already tried it, as you remember, on other typhoid patients. I begin by giving 30 grains a day, then a drachm, then a drachm and a half; I hope thus to obtain a purgative action, as well as a lowering of the temperature.

In the case of our patient, I have been disappointed in my expectations. The 17th of August we gave 90 grains. The temperature, which in the morning was $102\frac{1}{2}^{\circ}$ F., rose to 104° in the evening. There was no movement of the bowels following the large doses of the salicylate.

August 18th, the general condition was the same, that is to say, generally assuring. I increased the salicylate of magnesia to 2 drachms a day, in four doses of one-half drachm each. The temperature in the morning was 103° , in the evening 104° ; the patient remained constipated.

August 18th, a little more stupor. Tongue dry and black. Salicylate of magnesia increased to $2\frac{1}{2}$ drachms. Morning temperature $102\frac{1}{2}^{\circ}$, evening temperature 102° , a decline of one-half degree. Pulse small, rapid, and irregular.

August 20th, general condition is the same. Salicylate increased to $3\frac{1}{2}$ drachms. Notwithstanding these large doses, constipation persists. An enema was given in the evening, which resulted in five diarrhetic stools. Morning temperature 102° F., evening temperature $101\frac{1}{2}^{\circ}$; a fall of one-half degree.

August 21st, great increase of prostration; patient can hardly answer questions, his responses are vague and uncertain. There is some restlessness and agitation. The tongue is dry, the gums

fuliginous; meteorism much more pronounced; pulse very irregular. Discontinued the salicylate; N. B., to give wine, broth, quinine, and employ cold sponging. Morning temperature 102°, evening temperature 101.5°. About 4 p. m. the patient was suddenly taken with a violent delirium (delirium of action and of speech). It was necessary to put on a strait-jacket, and the entire night of the 21st, and the next day, he was in a state of extreme agitation.

The morning of the 22d, his condition was as follows: He lay on his left side, his head somewhat thrown backwards; the muscles of the neck slightly contracted, the eyes protruded and convulsed, turning upwards and to the right, the pupils contracted. The patient kept uttering plaintive cries. The mouth, wide open, gave issue to a frothy, sanguinolent mucus; the muscles of the face were the seat of fibrillary twitchings; the arms and the legs were stiff, and agitated by short, rapid spasms, ceasing for a few moments, and returning more violently than ever. The temperature had again risen to 104° F.: pulse still irregular.

In the presence of these complications, so marked in their expression, divers hypotheses suggested themselves. In order intelligently to appreciate these phenomena, their diagnostic and prognostic signification, I made successively the following suppositions: (1) Is it possible that our patient, whose occupation has been that of a painter, is now suffering from saturnine encephalopathy in the course of his typhoid fever? There was nothing to authorize this view of the case; there was no red line along the gums, he had never had any paralysis of the extensors or other manifestation of lead poisoning. (2) Have we here a case of uræmic eclampsia, supervening in the course of nephritis, a frequent complication of typhoid fever? There was no increase in the urine of albumen, which was even less in quantity than at the commencement of the fever. The temperature, far from falling, was higher; there was, moreover, stiffness of the neck, contracture of the ocular muscles, the delirium was very intense, and the patient was only at the tenth or twelfth day of the fever. For all these reasons, I decided that uræmia was not the cause. (3) Have we to do with simple nervous phenomena, a consequence of the aggravation of the fever? One certainly often sees, in the course of typhoid fever, which has been very regular during the past few days, a violent delirium set in with carphologia, general muscular tremblings, etc.; and at the autopsy, if the patient dies, which is not always the case, nothing is noted on the part of the brain but a well-pronounced hyperæmia of the meninges and gray substance. In our patient all the symptoms were too well marked not to indicate clearly, especially if due regard were paid to the contractures, the convulsive shocks, etc., a material lesion of the nervous centres, an inflammatory lesion developed in the course of typhoid fever; and on taking into consideration the symptomatic aggregate, in particular the contractures, the irregularity of the pulse, it seemed almost certain that the trouble was localized in the meninges. There was warrant for going even farther, and for positively affirming that the meningitis was seated at the base of the brain. This

was my conclusion, and the autopsy proved it to be correct.

You should remember that such cases, relatively speaking, are very rare. As I told you, the first nervous disorders of dothineritis have sometimes a great resemblance to those of meningitis, to wit, the headache, delirium, ocular troubles, the vomiting, the hyperæsthesia, etc. Hugues, who has carefully studied these facts, thinks that generally, we should exclude the hypothesis of meningitis or meningo-encephalitis as complications of typhoid fever. Nevertheless, Lèrèboullet, in a very able monograph, has shown that these meningeal accidents may be present in the stationary period (*period d'état*), or even from the very commencement of the fever.

"In the first class of cases," he says, "the stupor becomes extreme on the eighth or tenth day; the nocturnal delirium intense. At the same time vomiting sets in, there are oculo-pupillary troubles, convulsive movements, contractures, with fixation of the head backwards. Nevertheless, these symptoms, even when they all occur together, do not make the diagnosis sure. The temperature in general undergoes a relative depression, and presents oscillations of great irregularity; the pulse becomes, and remains during several days, irregular, slow, wavy; the respiration is also irregular and sighing. If in these conditions the delirium is intense, the cephalalgia violent, the face spasmodically distorted; if the eyes squint, meningo-encephalitis is almost certain."

You observe, gentlemen, how closely this description resembles the clinical tableau presented by our patient; and in this connection I must refer you to the classical treatise of Murchison. You will there see how difficult is the diagnosis in the presence of such symptoms. Having settled the diagnosis of meningeal complications, it was easy to foresee the fatal result which occurred in the course of a couple of hours.

The autopsy was made the 23d of August. These, in brief, are the results:

Abdominal Cavity.—The intestines were distended with gas (meteorism); their external surface (principally in the last portion of the ilium) injected and aborescent in spots. The small intestines were washed and incised along their convex border; a few feet above the cæcum a number of Peyer's patches were found in various stages of inflammation. Some of them, but little prominent, were softened; others were tumefied and firmer than the preceding; there were still others, very near the cæcum, which were ulcerated, the ulcerations having the form and size of Peyer's patches.

The mesenteric glands, notably enlarged, were soft and of a livid red color on section. The spleen very much hypertrophied (it was three times the ordinary size), was softened, so as to be diffuent, the parenchyma was of a reddish-dark color. The liver, a little congested, presented nothing worthy of note. The kidneys were large and congested; their capsules were removed with difficulty. Section of these organs showed only congestion.

Thorax.—The mucous membrane of the bronchi presented a deep red injection; it was lined by a viscid mucus; the lower lobe of the left lung

was congested and œdematous. There was the same condition in the right lung, but less marked. The tissue of the heart, a little discolored, offered nothing particularly worthy of note.

Cranial Cavity.—On removing the calvarium, the membranes of the brain were found congested; the superficial veins were very much engorged. The membranes over the convex surface were incised, and reflected back; the same state of hyperæmia was noted in the convolutions. At the base of the brain a purulent exudation was found over the optic commissure, and within the hexagon of Willis. This exudation was greenish-yellow, and adherent. It covered all the blood vessels and all the nerves of the region. On each side, in the substance of the pia mater, it extended along the sylvian arteries to the surface of the island of Reil. Over the tubercular quadrigemina, along the fissure which separates the cerebellum from the posterior lobes of the cerebrum, and between the crura cerebri, appeared the same exudation, and in large amount. Nowhere was there any trace of tubercle granulations. There was no œdema of the cerebrum. The spinal cord presented nothing worthy of note.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

The Bacillus Tuberculosis and the Etiology of Tuberculosis. Is Consumption Contagious?

BY H. F. FORMAD, B. M., M. D.

(Continued from page 368.)

From the examination of tubercular tissue from various sources, I may say that I have seldom succeeded in finding tubercle bacilli in newly-formed tubercular tissue made up of small lymphoid cells. In older tubercular tissue, made up of opaque epithelioid cells and giant cells with a nodular arrangement, particularly when this tissue is undergoing necrotic change, bacilli are quite common, except in some forms of tubercles of serous membranes, to be referred to later. Tubercle tissue that has undergone a complete cheesy change, contains the greatest number of bacilli. Cheesy matter of any source is a dead substance, and it is usually inhabited by bacilli, if these get access to it; while other bacteria are scarce on this nidus.

Examination of materials from the autopsy table shows that tubercle expresses itself in various manners. Primarily, tubercle occurs as a mere infiltration of lymphoid cells in the adventitia of blood-vessels, or as small nodular masses of lymphoid infiltration around blood-vessels or ducts of any kind; or tubercle tissue may organize within blood-vessels and various ducts. Sometimes tubercle appears as a diffuse lymphoid infiltration, extending over a larger area, showing a greater or less tendency towards the formation of nodes and cheesy or fibroid change, as in the lungs. Tubercle tissue may form masses of the size of a hen's egg, particularly in the brain and serous membranes. In the lungs, in racemose glands, and in mucous membranes, catarrhal

changes always follow the tubercle infiltration. On serous surfaces primary tubercles appear often as flat or nodulated patches of various sizes (in peritoneum), or as fungoid vegetations (in synovial cavities), or even as large plastic masses (in omentum). In the skin and mucous membranes, tubercles produce eruptions, ulcers or nodular indurations; in bones—caries, with abscess formation in surrounding parts (cold abscesses). Fibroid capsules, made up of connective tissue, due to reactive inflammation, enclose often smaller or larger tubercular masses, especially if these have undergone cheesy change.

Primary tubercle manifests itself quite variously in different animals. In Guinea-pigs and rabbits, it appears mainly as small cellular infiltrates; in dogs, it often undergoes a fibroid change; in goats, and especially in cattle, tubercle often forms large nodular, sometimes pedunculated masses, which often calcify;* in birds, it forms, preferably in the liver, large round mulberry masses, which, on section, appear sometimes as horny radiating structures.

Secondary tubercle presents an aspect entirely different from primary tubercle, and it manifests itself in nearly all instances in but one form, namely, as a fine milinary eruption representing those well-known gray semi-transparent nodules of the size of a millet-seed, called milinary tubercles. These seem to lie in the perivascular lymph-spaces, and are probably distributed throughout the body mainly by means of these lymph-channels of the blood-vessel walls. Tubercles do not occur in avascular tissues. There is, however, a second form of embolic or metastatic tuberculosis, which evidently distributes itself by the blood-current proper, and it appears in the form of conical masses or round nodes, which may reach the size of a walnut, and are located usually at the bifurcation of arteries. No mention of this form of tubercle is made in textbooks, although upon the post-mortem table this variety of tubercle is a very common occurrence; Especially is it seen in the lung and, more rarely, in the spleen and liver.

Taking into consideration the enormous frequency of local tubercular lesions (counting pulmonary phthisis into this category), the occurrence of secondary or true milinary tuberculosis must be considered as a rare affection. A tuberculosis affecting the lining of even the whole peritoneal cavity, including its lymphatic glands, or that of the pleural sacs, or that involving one or both lungs, must, when occurring thus in but one locality, be considered a local tuberculosis. In such instances, the tubercle spreads by continuity of structure.

It is a fact, established by Virchow, that tuberculosis is at first a local disease, and only becomes generalized secondarily. This generalization does not affect the blood like in infectious diseases, but it takes place simply as an embolic process like in some tumors. Local tuberculosis in external organs and accessible lymph-glands is

*I have met with, on the autopsy table of the Philadelphia Hospital, two cases of tuberculosis in man that were identical in every respect to bovine tuberculosis. Dr. Creighton, of Cambridge, England, describes a number of cases from his own observation, and collected from literature. Bovine Tuberculosis, London, 1881.

often a harmless affection. It is strongly related to primary tumors. Complete early removal of local tubercular lesions is practiced successfully in Europe. Volkmann and others have removed, for instance, lymphatic glands, testes, and joints affected with fungoid synovitis, with the object of preventing secondary tuberculosis, and have thus prevented a general miliary tuberculosis.

Nor should a gloomy prognosis be given in early phthisis. It is astonishing what a large number of healed cavities and cicatrices in the apices of lungs are found on the post-mortem table, indicating the healing of phthisis in persons who long subsequently died from some other causes in later life.

We have seen that tuberculosis manifests itself quite differently as to structure, appearance, distribution, and termination, in the various animals, and even differently in the various organs of one individual. Our studies have shown that these variations in the expression of tuberculosis depend upon the structural peculiarities of the various kinds of animals, and sometimes even upon the difference of the structure in animals of the same species. We have also seen that even in human beings tubercle tissue may manifest itself in various forms. In some individuals it develops rapidly, and spreads over large areas, becoming generalized and undergoing speedy cheesy change; in other individuals it develops slowly, fibroid change predominating; and in others the tuberculous product may calcify. In most individuals tubercular lesions may remain entirely local.

It is well known from clinical experience that the general condition of the organism has very much to do with the healing of a local tuberculosis. A local tuberculous inflammation may heal or become arrested in its progress, if the patient "gets strong," or it becomes more developed and aggravated if his general health "runs down." Observation has further shown that any simple non-specific wound in a weak, ill-nourished individual, may fail to heal, becoming unamenable to treatment, and probably assuming a tubercular character.

In some animals spontaneous tuberculosis is unknown, and while some animals are easily tuberculizable experimentally, in others tuberculosis cannot be produced.

It is in accordance with experience that in a large number of families the predisposition to tuberculosis is hereditary, and that their members die promptly of phthisis at a certain age from the effects of a simple "cold," while in the history of other families this affection is unknown. Every individual is liable to acquire syphilis, smallpox, and other contagious diseases, but it is proven that not every one can have tuberculosis. A special predisposition and a special individual are required. In such an individual, a simple inflammation resulting from any cause whatever, can produce tuberculosis.

Therefore, for the development of tuberculosis, two conditions are necessary:

1. A *definite* soil.
2. An *indefinite* irritant.

The reaction of the soil is always the same under the influence of any irritant, whether that irritant be a bacillus or not; since the result (tu-

berculosis) following a lesion in such a soil depends upon the character of the soil and not upon the character of the irritant, even though one irritant, say bacilli, may act more readily than other irritants.

In view of the demonstrated fact that simple injuries of any kind can excite a tuberculosis, but only in certain individuals and tissues, it is evident that tubercularization is determined by the kind of soil and not by a specific irritant. *Tubercle should, therefore, be defined as being an inflammatory new formation in a specific individual or tissue.*

What is the place for tubercle in pathology? The anatomical criterion for tubercle is a granulation tissue made up of lymphoid or epithelioid cells, which, on account of deficiencies in the soil, does not undergo any higher organization, nor tend to heal; but tends to form nodes and undergo cheesy change. Under favorable circumstances it may heal through fibroid change. The elements of tubercle tissue may spread by continuity of structure to surrounding parts, and occasionally tend to the production of metastasis, distributing themselves by means of the lymphatic system principally, and rarely by blood-vessels; and may generalize themselves through the whole body, forming miliary nodes or tubercles.

This miliary eruption of tubercle appears to have the same relation to the primary tubercular growth as the secondary metastatic cancer eruption has to the primary cancerous growth. Like in cancer, the elements of tuberculosis may be arrested temporarily by the lymphatic glands governing the affected region.

In tuberculosis, lymphoid cells form the nodes; in cancer, epithelial cells. While secondary cancer nodes are, as a rule, much larger than tubercle nodules on account of the well-known great proliferating power of epithelium, it is also a fact that cancer may appear as a miliary carcinosis, expressed by minute nodules not distinguishable macroscopically from miliary tuberculosis. Cancer is proven to be a local disease. It is not contagious. It is infectious only to the individual who is affected by it; i. e., it is self-infectious. And so is tubercle, in every respect, a local, self-infectious disease.*

That local manifestation of tuberculosis in the lung, which is designated by the traditional name of pulmonary phthisis, forms perhaps nine-tenths of all tubercular lesions, and hence deserves some special consideration.

I arrange myself with those who regard all forms of pulmonary phthisis as tubercular. There are only three or four lesion of chronic wasting disease of the lung which may be excluded from phthisis. These are atelectasis, or collapse from

*Cancer and tubercle are considered analogous lesions, and classed with tumors, by a number of pathologists. This fact would not make it inconsistent to call tubercle an inflammatory product, as the distinction between inflammatory processes and tumor formation is a purely arbitrary one. Virchow pointed out that the majority of tumors are purely inflammatory products (a statement antedated twenty years by Prof. S. D. Gross). A few years ago I made the question of the etiology of tumors a subject of careful personal study, which I yet continue, and I am forced to the conclusion that *all* true tumors are inflammatory products, and that no line of distinction can be drawn where the process which we call inflammation ends and where tumor formation begins.

pressure of effusions; bronchiectasis, in which the enormous dilatation of the bronchi may lead to large cavities and atrophy of lung structure; primary fibroid changes; and abscess of lung. Yet all these lesions may become tuberculous from secondary inflammatory changes which usually follow.

The lesions that are known as catarrhal pneumonia, broncho-pneumonia, pneumonic phthisis, cheesy pneumonia, tubercular phthisis, and fibroid phthisis, are all manifestations of the one disease. Such a classification may be, however, entirely justifiable and useful for practical, clinical and therapeutic purposes. Pathologically considered, phthisis is a local tuberculous inflammation of the lung which may manifest itself in various ways, the appearances depending upon the duration of the disease, the mode of onset, and the constitution and condition of the patient. Lesions representing the different forms of phthisis, and their transition from one form to the other are often seen in the same lung.

Virchow insists that nothing should be considered tubercular unless it shows true tubercle nodules, and hence he does not recognize cheesy pneumonia—or cheesy hepatization, as he calls it—as tubercular, although he does not object to the term phthisis for this lesion.

I was fortunate enough to attend several times the classical demonstrations on this point of Virchow, the father of the view of the dual origin of cheesy matter and phthisis; yet, from our present knowledge of what constitutes tubercle, I cannot help interpreting all the forms of phthisis as of a unitarian origin. It is, after all, as Virchow himself says, only a matter of nomenclature. If we consider the presence of bacilli of Koch as the differentiating point between what is tubercular and what is not, we find that catarrhal and cheesy pneumonias are the most tubercular of all, because they contain, as a rule, more bacilli than any other forms of phthisis.

Although cheesy pneumonia, like all forms of phthisis, remains commonly a local affection, it is seen on the autopsy table to give rise to miliary tuberculosis at least as often as any of the other forms of local tuberculosis.

We are then at present at the same standpoint in regard to the character of tubercle and cheesy matter as Lænnec (1819); and it is indeed perfectly reasonable to suppose that any cheesy matter found in a scrofulous person or animal is tubercular. Of course it is evident that tuberculosis of the lung is usually accompanied by simple inflammatory products, such as organized connective tissue (chronic phthisis), or unorganized croupous and catarrhal exudates (predominating in acute phthisis), which may undergo rapid necrotic and purulent changes, resembling cheesy material. For the latter products the name "coagulation necrosis," as applied by the Heidelberg and Leipsic people, may be employed. Tubercle bacilli are commonly found in this coagulation necrosis. True tubercular cheesy matter should, I think, be considered only that product which is derived from the breaking-down of previously well-organized tubercle tissue.

I need not refer to the details of the manifestation of tubercle in the lung, as these are too well known. But I would like to remark here that

those small whitish or gray nodules, usually of somewhat irregular shape, which are seen more or less densely scattered throughout the parenchyma of lungs affected by phthisis, are not miliary tubercles, but minute foci of broncho-pneumonia.*

These minute broncho-pneumonic foci take their origin from tuberculous matter disseminated by means of air-passages, as explained before. *Miliary* tuberculosis of the lung distributes itself by means of the perivascular lymphatics, is very rarely accompanied by catarrhal changes or hepatization, and rarely arises from a primary tuberculous focus of the lung itself; it is, as a rule, a part of general tubercular disease.

2. The Predisposition.

Having shown that for the production of tuberculosis we need a special soil, and that the irritant is only of secondary significance, some inquiry into the nature of this soil is necessary.

The question of the predisposition to tuberculosis, as it stands at present, must be considered from three aspects:

1. The clinical aspect.
2. The anatomical aspect.
3. The bacteridian or parasitic aspect.

The consideration of the clinical aspect of the predisposition to tuberculosis is invaluable, as it rests mainly on actual observation, on demonstrated clinical facts, and on conclusions drawn from statistics.

From time immemorial, a clinically well-defined condition of the system, known as the strumous diathesis in its various forms, has been recognized. This condition will be considered later on.

There are a number of ailments which, from the experience of clinicians, are known to have a great, direct or indirect, influence in the development of general tuberculosis and pulmonary phthisis; or are known to create conditions of the system that predispose it to this malady. Such are syphilis, inflammation of serous membranes, bronchitis, croupous pneumonia, diabetes, the exanthemata, especially measles and typhoid fever, deformities of the skeleton, rickets, cerebral and spinal diseases of various kinds, dyspepsia, the puerperal state, uterine diseases, prolonged nursing of children, onanism, change of climate, continuous loss of sleep, distress, etc.

That exhaustion, exposure, the deprivation of food, and other hardships of campaign life, etc., are prominent etiological factors in the production of pulmonary consumption, is learned from the accounts of military surgeons, who observed among young, robust soldiers a remarkable increase in the morbidity and the mortality of phthisis, during and immediately after the close of a war. Such observations have been made in the Franco-Prussian and Turko-Russian campaigns. The fact that consumptive soldiers are not allowed to enter upon a campaign (certainly not in Germany and Russia) excludes here the probability of contagion.

Statistics also show the remarkable prevalence of phthisis in persons of certain occupations, such as stone-cutters, miners, cigar-makers, weavers,

*See, in connection with this, the excellent studies of Wm. H. Mercur, from the pathological laboratory of the University of Pennsylvania, published only in abstract form in the *Philadelphia Medical Times*, July, 1883.

telegraph operators, book-keepers, and persons engaged in certain other occupations of a more or less sedentary nature. It is more natural to suppose that the disease or the predisposition to it is created by the character and the conditions of the occupation, than that a contagion should affect preferably shoemakers, miners, or soldiers in the battle-field. Again, in most phthisical patients the beginning of the disease can be plainly attributed to an exposure, to a "cold."

On the other hand, there are pathological conditions or diseases which appear to prevent the development of phthisis and tuberculosis in general. It is an established clinical fact that phthisis is extremely rarely, if ever, associated with mitral heart-disease; and, from my own observations, I believe that phthisis is rarely coincident with tumors. For the latter circumstance, I can offer no explanation; nor is there any statement to this effect in literature. Rindfleisch has suggested that heart disease prevents the development of phthisis by inducing repeated slow congestions of the lungs, these congestions producing an overgrowth of the muscular tissue of the bronchioles and air-vesicles, which thus gains strength for repelling the exudates following inflammation.

If tuberculosis were depending upon a contagium for its development, neither heart nor tumor disease, nor any condition of the organism, could ever prevent its occurrence.

All the clinical facts above referred to prove definitely the necessity for a predisposition for the development of tubercular disease, and militate against the necessity of a contagium.

The anatomical aspect of the question—the morphology of the soil in which tubercle develops—is the most important aspect.

Beneke* tries to explain the disposition to tuberculosis by a disproportion between the size of the heart and blood-vessels and other organs to the bulk of the body.

Schottelius† made recently some interesting observations concerning the mode of termination of the smallest bronchioles, and their relation to the lung acini in different animals. He found that in the carnivora the entrance of the bronchioles into the acini presented very small apertures, so that the air-vesicles were not easily accessible to irritants; while in the herbivora the terminal bronchial terminations were quite wide, thus permitting the free entrance of irritants. He states that in man the bronchial terminations congenitally approach sometimes those of the carnivora, and sometimes those of the herbivora. In the latter type, he believes he has found anatomical explanation for the predisposition in some in some individuals to pulmonary tuberculosis.‡ Weigert, of Leipzig (one of the most enthusiastic germ-theorists), properly remarks upon the observation of Schottelius, that it does not explain the predisposition, as the same animals will react, upon the introduction of the "poison of tuberculosis," into any other part of the body, where the bronchioles do not come into play.

My own studies upon the minute anatomy of the tissues of man and of animals predisposed to tuberculosis, extended over a large amount of material, and gave results which, to my mind, satisfactorily explained this condition. These results I announced at a meeting of the Society in October, 1882.

The anatomical peculiarity observed in either man or animals, be it inherited or acquired, I first showed to be, briefly stated, as follows; all the tissues of the body approach somewhat an embryonal type—they are peculiarly rich in nuclei and young cells, and the lymph-spaces of the connective tissues are narrower, fewer in number, and show a great many more cellular elements in the serofulous than in the non-serofulous. So far, subsequent observations of others agree with mine. Objections are raised only as to the direct relation between these structural peculiarities and tuberculosis. Here I must state that I only suggested, and never asserted, the necessity of such a relation. It is quite possible that there are some other and more striking peculiarities in the morphology of serofulous animals yet undiscovered. This much I can, however, reassert to-day: that tuberculosis usually ensues when a simple inflammation is set up by any kind of injury, in animals with the structural peculiarity which I have described; but tuberculosis cannot be produced in animals that do not have this structural peculiarity, so far as my experiments show, unless the injury is inflicted upon serous membranes.

For the details of my researches in this direction, I must refer to my first paper upon this subject.*

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Discussion on the Specific Treatment of Typhoid Fever.

(See page 391.)

Dr. Arthur V. Meigs said: This so-called "Specific Treatment of Typhoid Fever" appears to me a mistaken plan founded upon an untenable theory. We are asked in the first place to assume that typhoid fever has for its cause a germ whose very existence is not known, and second that calomel, iodine, and carbolic acid, given by the mouth, will meet with and destroy this imaginary germ. Neither of these assumptions can be considered proved. Why do we not give the same drugs in cases of scarlet fever, measles, or smallpox?—for there is as good reason to believe them to originate from germs, and that the same germicides would be effective for their destruction. I should not be so outspoken in my denunciation of this method of treatment if it could be looked upon as harmless; but it seems capable, on the contrary, of much mischief. Whatever may be the effect of such large doses of iodine and carbolic acid, we were almost all taught and have up to this time believed the effect of purges given in the earlier stages of typhoid fever to be most disastrous. Dr. Wilson himself, I doubt not, was taught, as I was, when a resident physician in the Pennsylvania Hospital, that even a teaspoonful of castor oil given to a

† Virchow's Archive, vol. xci, 1883.

‡ The method of investigating this condition is not without interest. The vesicular structure of the lung was injected, through the bronchi, with a resinous melted mass, which, on cooling, presented molds of the bronchioles, in connection with their characteristic infundibula and acini.

* Loc. cit.

patient in the early stage of the fever might cause a diarrhœa which would continue throughout the attack. Is there no reason for this belief, and is not calomel capable of producing the same effect? Dr. Wilson says the treatment of typhoid fever is at sea; to me it seems on the contrary that there is no disease in regard to the treatment of which there is such general agreement. How many men in this room treat cases of scarlet fever alike, and how many treat typhoid fever differently? The present treatment of the disease is the treatment of common sense; so far as the local lesion is concerned, we treat it as a surgeon treats a wound—we try to give the part rest, and avoid all causes of irritation, and nature thus is given time and opportunity to heal the ulcers. We treat symptoms as they arise, and support the strength of the patient with food and water, and stimulants if necessary, through the four or six weeks during which fever is burning his tissues until he is reduced almost to a skeleton. Now, can purging with calomel, or administering such nauseous drugs as carboic acid and iodine, conduce to this result? Will the patient be any better able to go through his weeks of fever? Does Dr. Wilson show that the method shortens the duration of the disease one day, or one hour? It appears like asking us to go back to the days of ignorance, which existed before Stokes, and Graves, and the great men of that day, taught us how to treat the disease. Years ago Stokes put in a few words the common-sense view of the question. It must be remembered that at that time distinction between typhus and typhoid fevers was not drawn. He says: "I confess that it was not until several years after I commenced practice that I became fully aware of the erroneousness of what is termed the anatomical theory of disease; and I feel certain, humiliating though the confession may be, that the fear of stimulants in fever with which I was imbued, was the means of my losing many patients whose lives would have been saved, had I trusted less to the doctrine of inflammation, and more to the lessons of experience, given us by men who observed and wrote before the times of Bichat or of Hunter.

"The hospital physician will be frequently asked by students to state the principle on which he administers wine in fever. Typhus fever is a disease which has a tendency to a spontaneous and favorable termination, but one in the course of which the powers of life are attacked by a most malignant influence. By wine, food, and other stimulants, we support nature until the struggle is past, so that, to use the words of an ancient author, which embody a more profound principle than appears at first sight, we 'cure the patient by preventing him from dying;' that is to say, we prolong his existence until the natural and favorable termination of the disease arrives. We do not allow our patients to die of exhaustion, and bearing in mind the depressing influence they have to struggle with, we give stimulants at the proper time and with a bold hand. We give our patients an artificial life till the period arrives when nature and health resume their sway."

If we are asked to try the method because it lessens the death-rate, I think that can hardly yet be considered as proved. The number of cases recorded by Dr. Wilson is yet too small to prove

any point. In looking over some old lectures of my father, the late Dr. J. Forsyth Meigs, delivered about the year 1850, I found that he reported a series of sixty-nine cases treated in private practice, and only five deaths. This makes a death-rate of 7.24 per cent., while Dr. Wilson's series of thirty-two cases and two deaths makes the death-rate 6.21 per cent. The number of cases treated by him is less than half. The cases reported by Dr. Meigs were treated when bleeding and purging were still customary, and even his results are but little inferior to those of Dr. Wilson, and both are infinitely better than any published hospital statistics. In the first thirty-nine of Dr. Meigs's series of cases he had four deaths; but in the thirty coming afterwards, only one death occurred. These results bear comparison with Dr. Wilson's, particularly the second series, which came after the first, and when bleeding and purging were becoming less the medical fashion of the day, and the expectant plan was more pursued. A comparison of the first and second series of cases shows how little reliance is to be placed upon deductions drawn from the treatment of such small numbers; for in the first the death-rate was 10.25 per cent., while in the second it was only 3.33 per cent. An examination of such records as I possess enables me to recall twenty seven cases I have treated in private practice. Of these, two died, making a death-rate of 7.40 per cent. One of the deaths was of a boy who was taken sick in a house where there were eight or nine cases of diphtheria and diphtheritic sore throat, almost every one living in the house at the time being more or less affected—the cause being a foul, leaky brick drain which ran through the cellar. The other death was of a man about fifty years of age, in whom the diagnosis was not made until about the end of the second week of the disease. During the first two weeks he was in and out of bed, and made at least two journeys of sixty or seventy miles by rail, and finally died of perforation of the bowel and peritonitis, which were found at a post-mortem examination. If the total number of cases reported by Dr. Meigs and my own be considered together, there were treated in private practice ninety-six cases with seven deaths, making an average death-rate of 7.29 per cent—not a bad showing for the old treatment, when it is considered that typhoid fever has always been looked upon as one of the most fatal of all diseases.

Selling His Practice.

A physician sold his practice, and agreed not to practice "in that city or its vicinity." He broke this agreement, and his successor brought suit for an injunction, which was granted to him generally. The case was carried to the Supreme Court of Michigan, where the decree was confirmed. The Court defined the term "city or its vicinity" to include the territory surrounding the city for the distance of ten miles from its corporate limits. "The extent of territory, in the matter of doing business, included in the term 'vicinity of the city,' must necessarily depend in a great measure upon the size of the city, its location, and particular surroundings."

EDITORIAL DEPARTMENT.

PERISCOPE.

Koch on Cholera.

The *Lancet*, February 23, 1884, says:

Our Berlin correspondent has favored us with the following Fifth Report of the German Cholera Commission, which he correctly says is of such importance that it does not permit of abridgment. Dr. Koch writes from Calcutta, January 7:

"As a sequel to my report of December 16 last concerning the work of the Cholera Commission in Calcutta, I have the honor of sending to your Excellency the following account. The Commission has been gratified with the lively interest and active support given by the local and hospital authorities in this city. Nearly all fatal cases of cholera in which dissections were made the city hospitals were thus available for our researches. Up to the present time the material has been collected from nine post-mortem examinations, as well as from eight living individuals, suffering from cholera. The cases following each other in almost equal intervals, the time was just sufficient for a thorough examination in all directions. Some cases, ending fatally after a short illness and uncomplicated with other morbid conditions, furnished the best material for examination, as post-mortems could be made soon after death. To these favorable conditions it is due that the Commissioners have been able to make essential progress in the advancement of the work entrusted to them. Microscopical examination in all cases confirmed the existence of the same bacilli in the cholera intestine, which had been found in Egypt. However, in my report of September 17, I was obliged to leave it undetermined whether these bacilli do not belong, like so many other bacteria, to the regular parasites of the human intestine, which under the influence of the choleraic process are enabled to penetrate within the mucous membrane. At that time sufficiently marked characters were still lacking for distinguishing these bacilli from other intestinal bacilli of a very similar shape. But this want has now fortunately been supplied; for with the aid of the methods pursued by the Board of Health, which have also proved most reliable on this occasion, we succeeded in isolating the bacilli from the intestinal contents of the least complicated cases of cholera, and in cultivating them in pure cultures. A minute observation of the bacilli in these pure cultures has led to the discovery of some very characteristic peculiarities as to their shape and mode of growth in gelatine, by which we have been enabled to distinguish them with certainty from other bacilli. We had now the means for definitely deciding the question whether these bacilli belong to the ordinary inhabitants of the intestine, or whether they exclusively occurred in the intestine of individuals suffering from cholera. For this purpose, again by aid of the gelatine cultures, we endeavored to demonstrate the bacilli in the choleraic discharges and in the intestinal

contents after death from cholera, in which task we succeeded in all the cases examined in this city. On the other hand, a similar examination of the intestinal contents in other diseases gave evidence that the bacilli met with in cases of cholera were invariably absent. Thus far the research has been carried out on the bodies of six cases of pneumonia, dysentery, phthisis, and kidney disease. Nor has it been possible to find bacilli similar to the cholera bacilli anywhere in the intestinal contents of animals, and in other substances abounding with bacteria.

"If these observations should be confirmed on further investigation, a very important result will have been gained. Indeed, if these bacilli, endowed with specific properties, belong quite exclusively to the cholera process, the etiological connection between the prevalence of the same and the cholera would barely admit of doubt, even if the reproduction of the disease in living animals should fail. But in this latter respect things seem to be in our favor, since several experiments recently made on animals have given results which allow us to hope for further success. Besides these experiments, the Commission has been occupied with getting the best possible information about the behaviour of cholera in the city of Calcutta. In cities outside of India, which are only exposed at long intervals to cholera infection, it is impossible to make out with certainty the influence exerted on this disease by sanitary improvements, such as the supply of good drinking water, drainage of the soil, etc., since it must always be a matter of chance whether such a locality be once or often the seat of the disease. But in cities like Calcutta, which every year have a high mortality from cholera, each measure that operates successfully against the disease must be followed by a more or less remarkable and lasting decrease in the mortality. As a matter of fact, in Calcutta the cholera has decreased in a striking manner since 1870. Before this year the annual average mortality was 10.1 per 1000 inhabitants. Since 1870 it has fallen to 3 per 1000, or more than threefold. This fact, deserving the utmost attention, must carry indications on the most successful means of attacking the disease. The physicians of this city nearly all agree in the opinion that the decrease of the cholera is solely owing to the introduction of a drinking-water supply. It will be an important business for the Commissioners, by personal study and inspection, to arrive at an unbiased judgment on this point. For this end they have visited the waterworks as well as the sewage arrangements of Calcutta. A number of samples of river water, before and after infiltration, in the waterworks of Puttah, have also been examined, and the drinking water supplied to the city has been found of excellent quality.

"I learn from the medical journals that the French Commissioners sent to Egypt to investigate cholera declare in their report that they have gained other results than those communicated by myself, having found organisms in the blood al-

leged to be peculiar to cholera. Since this might give rise to the impression that the researches of the German Commission were going in a wrong direction, I think it necessary to state to your excellency my views upon the above statements. In the blood of the healthy man, besides red and white blood-corpuscles, there exist, in varying numbers, small, roundish, pale elements, the so-called blood-plates (*Blutplättchen*). In some febrile diseases—typhus fever and pneumonia, for instance—these elements are greatly multiplied, and, in consequence of their resemblance to micro-organisms, have been repeatedly taken for bacteria. In the blood of individuals suffering from cholera, and of those who die from this disease, they are almost always increased, as we were able to ascertain in the cases of cholera examined by us. This fact, after all, is not a new one, having been already mentioned by former investigators. Dr. D. Cunningham, for instance, as early as 1872, in his 'Microscopical and Physiological Researches into the Nature of the Agents producing Cholera,' has given a very good figure of these formed elements of the choleraic blood. Now, since even the most approved methods of examination do not permit of the recognition in the cholera-blood of any other elements similar to bacteria, and since the description given by the French Commission corresponds in every way with the above-mentioned blood-plates, I cannot but argue that the French Commissioners, falling into the same error as previous investigators, have mistaken the 'Blutplättchen' for specific organisms. Any etiological connection with cholera cannot be ascribed to these blood-plates, because, as I already mentioned, these elements are also met with in the blood of healthy individuals, and others suffering from other diseases."

Since the publication of the above, a telegram from Calcutta announces that Drs. Koch, Fischer, and Gaffky have discovered the cholera-bacillus in a water tank.

Physostigma and Eserine in the Night-sweating of Phthisis.

Dr. William Murrell thus writes in the *Practitioner*, December, 1883:

On theoretical grounds, it might be supposed that physostigma would be useful in the treatment of sweating. It is allied in its physiological action to jaborandi, pilocarpin, and muscarin, whilst it is antagonized by atropin, daturin, hyoscyamin, and homatropin.

I have used physostigma and the salts of its alkaloid in the treatment of the night sweating of phthisis for nearly two years, and have notes of over fifty cases. Of these, thirty-three were males and seventeen females. Of the adults, thirty-eight were between the ages of twenty and thirty-nine. The oldest patient was forty-nine, the youngest was a girl of four. They were all out-patients at the Royal Hospital for Diseases of the Chest, and they were all suffering from phthisis. Their symptoms were those usually met with in these cases—cough, expectoration, more or less hæmoptysis, loss of flesh, and night-sweating. With regard to physical signs, all stages of the disease were represented; in some there was simply consolidation, others had moist sounds

over the chest, and in others, again, the indications of the existence of a cavity were apparent. The sweating was in every instance profuse, only well-marked cases being selected for observation. It is hardly necessary to say that whilst the physostigma was being taken no other treatment was adopted. The only exception to this was in the case of cod liver oil. If the oil had been taken continuously for some time, it was thought better to allow the patient to go on with it, rather than to introduce a disturbing element by discontinuing its use.

Of the fifty cases, thirty-four were treated with physostigma itself. The preparation was the extract, the dose one-tenth of a grain made into pilules with sugar of milk. In ten cases one pilule only was given at bedtime, and in eight of these, the sweating was completely arrested by the fourth or fifth night. Of the two cases of failure, one was relieved by two pilules of physostigma at bedtime, and the other by a twenty-grain dose of agaric. In twenty-four cases the physostigma pilules were given three times during the night, and this gave even better results. In most cases the sweating was checked the first or second night, and in every case it had almost ceased by the end of the week. In some cases, where there was profuse sweating during the day as well as at night, a pilule was given every four hours. The dose is too small to produce "untoward effects," and no hesitation need be felt in repeating it frequently. The sweating once stopped, does not, as a rule, return for three weeks or a month, but at the expiration of that time it is usually necessary to resume the treatment. In two cases in which the physostigma failed to act promptly, Shoemaker's oleate of zinc was used as a dusting powder at bedtime with excellent effect. This new oleate is a beautiful greyish-white soft powder; but as it has a slight, though hardly perceptible, odor, it should be prescribed with the addition of $\frac{1}{100}$ part of thymol. The combination is a pleasant one, and succeeds admirably, not only in excessive sweating, but as a remedy for many acute and irritable skin diseases.

I have used three salts of eserine—the hydrobromate, salicylate, and sulphate—and all three answer equally well. The dose best adapted for the treatment of excessive sweating is the sixtieth part of a grain, and this may be conveniently made into pilules, one to be taken three or four times during the night. In fifteen consecutive cases in which I gave them I had no failures, although it is hardly likely that this mode of treatment will succeed in every case.

Physostigma is undoubtedly a good remedy for excessive sweating, but there is no reason to suppose that it will take the place of other and better known modes of treatment. It may be said that we have now so many remedies for sweating, that practically it is not desirable to extend the list. This may be true; but on purely pharmacological grounds the use of Calabar bean to check sweating is of interest.

In one case of phthisis I gave the patient at intervals six hypodermic injections of a sixtieth of a grain of sulphate of eserine. The temperature was taken every four hours for six weeks, but I could not see that it influenced it in any way.

The Treatment of Bright's Disease.

From an article by Dr. N. M. Baskett, in the *St. Louis Courier of Med.*, January, 1884, we note as follows:

The diagnosis being made, the question of treatment occurs; and I shall give my own plan of treatment. Most of the authors object to the use of mercurials in Bright's disease, because the system is so easily ptyalized. This may be true, but in the acute form of the disease I consider them the most reliable agents we have for its successful treatment. I always use them, and have never yet salivated a patient. My usual plan, if there is much œdema, with impeded heart-action, is to give the following recipe:

R.	Hydrarg. chlor. mit.,	gr. ss.
	Sodi bicarb.,	grs. ijss.
M.	Ft. chart No. j.	
S.	One powder twice a day.	

In conjunction with this, I give night and morning:

R.	Potass. bitart.,	ʒj vel jss.
	Jalapœ pulv.,	grs. viij.
	Gambogia pulv.,	gr. j.
M.	Ft. chart No. j.	

Should this not cause an elimination of the watery elements rapid enough, and there is danger of uremic coma or apoplexy from retardation of the blood, I add:

R.	Pilocarpin muriat.,	gr. j.
	Sacchari lactis,	grs. x.
M.	Ft. chart No. x.	
S.	One three times per day.	

For the action of the heart and system, I use the following tonic, varying the ingredients to suit the exigencies of the case:

R. Potass. iodid.; tinct. digitalis; syr. squills; liq. ammon. acetat.; fl. ext. phytolac dec.; syr. sarsap. comp.

These ingredients, given according to the age and condition of the patient and the effect desired.

Under this treatment my acute cases have always improved rapidly. I have always seen a cessation of the graver symptoms in a few days. Of course I do not continue the mercurials long after the dropsy is subdued. But I have frequently found it necessary to return to them when the symptoms manifested themselves, and always with benefit.

In the chronic condition, the most that can be done is to keep the bowels regular and build up the system with tonics. For this purpose, I find nothing better than the comp. jalap powder, the alterative mixture mentioned above, and a teaspoonful of the ferri nitrogeniz. comp., as manufactured by Chapman, Green & Co. This to be taken three times per day, after meals. Occasionally I find it beneficial to give the powders of pilocarpin three or four days in succession.

With these measures, these patients will enjoy a fair degree of health, and be able to attend to the lighter forms of labor. In the last two years I have attended five cases of acute and chronic albuminuria. None of these patients have died of the disease. One of them, an old gentleman, sixty-seven years of age, died a few weeks ago of capillary bronchitis, with which he had suffered for years.

The question of dietetics during the disease is discussed by many writers. Of course, I always

caution my patients to avoid indigestible food. Anything disagreeing with them in health will certainly disagree during the disease. But beyond this I do not limit them. Some authors condemn the use of albuminous foods, which, to me, seems a great mistake. Albumen is essential to life. The waste going on in the system can only be supported by a constant supply of material. If it is not furnished with the food, the tissues of the system will be broken down to supply it. In fact, it is highly probable that the albumen is supplied from tissues of the system. Let the patient eat, then, anything which agrees with his digestive apparatus, and trust to the recuperative powers of nature and proper remedial agencies to eventually re-establish a normal equilibrium.

The Organic Phosphorus in Urine.

The *Lancet*, January 5, 1884, says: Glycerin-phosphoric acid has been found in the urine in leukæmia and in certain cases of chyluria, and there is now reason to believe that in extremely minute quantities it is a normal constituent of urine. Sotnischewsky has shown that if the phosphoric acid in urine be estimated in the ordinary way, after the urine has been boiled for some time with strong nitric acid, the amount of phosphoric acid indicated is more than that of the same urine which has not been so treated—the inference being that the boiling with nitric acid oxidizes the phosphorus in combination with organic matter in the urine. Zuelzer confirms Sotnischewsky, and, in addition, has made a series of observations on healthy animals under varied conditions of diet, etc., and also in various diseases in man. He finds that the amount of what for convenience we designate organic phosphorus is extremely small in healthy individuals on ordinary diet, but that it is considerably increased by feeding with brain substance and fatty matters. The morbid conditions in which the most marked increase occurred was in a case of dementia, and in several instances after the administration of chloroform. In a case of diabetes, the amount found was also considerable. These observations are of interest as being likely to elucidate several obscure points with regard to the tissue metamorphosis that occurs in nervous diseases. Hitherto the evidence obtained by an estimation of the phosphates in these diseases has been disappointing, and of a negative character. But if, as is very likely, the phosphates present in urine only represent the normal tissue metabolism of the body generally, and the glycerin-phosphoric acid that of the phosphorized constituents of the nervous system, then it is not a matter for surprise that our labors in the past have been so unsatisfactory, since we have not recognized the possibility of phosphorus being found in the urine in this form. In future investigations it will be necessary to determine both separately, and to clearly express their relationship. When this has been done in a series of cases, there can be little doubt that we shall be able to discriminate between the increase of phosphoric acid due to general tissue metabolism and that caused by disturbances of nutrition in the nervous system, and thus elucidate the mysterious rôle played by phosphorus in the organism generally.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT MEDICAL LITERATURE.

—A case of multiple sarcoma of the skin, closely resembling leprosy, is described in a brochure by Dr. James Nevins Hyde, of Chicago.

—An interesting pamphlet on the therapeutic uses of peroxide of hydrogen, especially in diphtheria, has appeared from the pen of Dr. R. J. Nunn, of Savannah, Ga. He records some striking observations, and certainly this curious agent merits closer investigation.

—There are 50,000 insane persons in the United States not in asylums. How they should be cared for is one of the main questions of an essay by Dr. Samuel Ayres, of Pittsburgh. He stigmatizes as a mistaken idea the one which so generally prevails, that because a person is insane he must be sent to an asylum. Insanity in its forming stage may be easily cured, and there is no necessity for inflicting upon patient and family the mortification and grief of asylum confinement.

—A case of epithelioma arising from local irritation is recorded by Dr. J. Solis Cohen in a late reprint from the *Laryngological Transactions*.

—In a reprint from the *Columbus Med. Jour.*, Dr. W. H. Phillips writes an article in favor of the more extended employment of hydrotherapy. His suggestions are timely, and his points well taken. He shows that the good results do not depend on any curative element in the water, but on its intelligent application as an alternative, detergent and stimulant.

BOOK NOTICES.

A Year-Book of Surgery for 1883. Edited by Charles H. Knight, M. D. 8vo., pp. 147. Price \$1.50.

A Year-Book of Therapeutics for 1883. Edited by R. W. Amidon, M. D. 8vo., pp. 247. Price \$1.50. G. P. Putnam's Sons, N. Y. City.

We cannot speak with much commendation of these compilations. It is not obvious what use they subserve. Made up, as they are, from extracts more or less condensed from a few leading journals, they are a poor substitute for the quarterly or semi-annual abstracts published, which can be had for less money, with more frequent issue, and containing more matter, at least as well arranged. The Year-Book of Surgery has no index, that of Therapeutics but a slight one,

which does not name several important additions to our remedial resources within the time included.

A Plea for the Cure of Rupture; or, The Pathology of the Subcutaneous Operation by Injection for the Cure of Hernia. By Joseph H. Warren, A. M., M. D. Boston: James R. Osgood & Co.

The author of this monograph explains in a series of short chapters the method he employs for bringing about obliterative inflammation in hernial protrusion by deep injections. He answers the questions which would be apt to suggest themselves to surgeons, and cites a number of cases.

The Veins of the Brain and its Envelopes, their Anatomy and bearing on the Intra-Cranial Circulation. By William Browning, M. D. F. B. O'Connor, jr., Brooklyn, N. Y.

This anatomical and pathological study has been carefully carried out, and the author deserves credit for the thoroughness of his researches. The topic is one intimately associated with important pathological and clinical facts, and this has been borne in mind and frequent applications made.

Report of the Secretary of the State Board of Health of West Virginia for 1881-3. Wheeling, Va.

In this volume of 300 pages a large amount of useful information is condensed. Besides the proceedings of the Board, a number of special pages are inserted from competent hands on topics of value to the public, and generally put in such language as can be understood by ordinary readers. Thus some sensible advice is given on nursing the sick, on preventing malarial disease, on the care of the eyes, on ventilation, on the use of tobacco, etc. Although the profession may not find much that is new, the people at large cannot be too often or too thoroughly instructed on these points of daily hygiene. There are also some well-prepared articles on veterinary medicine and a number of pages of statistical information.

The Pathology and Treatment of Gonorrhœa. By J. K. Milton. Fifth edition. Wm. Wood & Co.

The work of Mr. Milton is a sensible one, based on personal observation in a great city (London), and expresses opinions little due to echoing the words of any master. Hence, while his treatise is fresh, readable, and suggestive, he has an arbitrariness of judgment, a positiveness of praise and condemnation, against which the younger reader should be on his guard. Few will be disappointed in its perusal, and none can fail to derive many useful hints from his pages.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

The COMPENDIUM, formerly published every six months, appears now *every three months*. It is compiled with special reference to being taken *with the Reporter*, and none of the articles which appear in our weekly are reproduced in our quarterly publication. It is made up exclusively from other sources.

Each number of the *Quarterly Compendium* contains 150 pages of reading matter, carefully selected from American, British, and European medical journals, with a special view to the wants of the American physician. It is on excellent paper, and neatly bound in pamphlet form, with full table of contents and index.

The price of the COMPENDIUM is 75 cents a number, or \$2.50 a year; and it will be found well worth it. But when taken with the REPORTER, we offer the two journals at the very low price of SIX DOLLARS, when paid for *strictly in advance* and directly to this office.

THE NEW YORK STATE MEDICAL ASSOCIATION.

In a pamphlet of 43 pages, this Association, "founded February, 1884," assigns the reasons for its existence, and reports the proceedings of its first annual meeting.

As the profession knows, it was a question of "Code" or "No Code." The disreputable manner in which a conclave of New York city specialists managed to gain control of the New York State Medical Society, and commit it to action destructive of professional honor, is set forth in clear terms. It is proved that on a fair and full vote both the membership of the Society and the profession of the State of New York are opposed to the position of the State Society by a heavy majority. As Dr. Austin Flint remarked:

"The 'New Code' in effect removes the barrier dividing members of the regular profession from irregular practitioners; and, in this point of view, it is the sentiment of a large majority of the medical profession of the State, that the adoption of the 'New Code' will prove greatly detrimental to the honor, the interests, and the usefulness of the profession."

Nothing is more true than these words. No action is more certain to degrade the profession in the eyes of the public, and in the understanding of sound-thinking men, than this deliberate overthrow of the barrier between the regular, scientific practitioner, and every ignorant quack who manages to hold a diploma.

The physicians of New York, those who respect the honor and welfare of the profession more than some few consultation fees, have done well to cut loose from a clan of specialists, who have at heart only their own profit as a motive of action, and to it are willing to sacrifice not only their professional honor, but the honest sense of the Medical Society of their State.

One remark of the chairman of the meeting, Dr. H. D. Didama, we take occasion to quote:

"One other matter is worthy of consideration. The remarkable activity of a few leaders of the minority is well known. They have been aided by certain medical journals in New York and elsewhere. These journals, in violation of all sense of propriety, have received our money for their support, and have then, week after week,

thrust their misrepresentations, their boasts, their puerile arguments, and their pitiful sophistries, into our unwilling faces.

"I need not intimate that there is a remedy for this evil also; that there are medical journals, able and deserving our support, and disposed to give us at least civil treatment."

We have observed the fact here stated—the singular warmth of certain journals for this ill-advised movement. By so doing they are working a personal injury to every one of their subscribers, except, perhaps, specialists in large cities, and these will feel it sooner or later. They should be made to see that they do not represent the opinion of the profession, and that their course is one destructive of its best interests.

ALBUMINURIA VS. BRIGHT'S DISEASE.

A few years ago, when albumen was detected in the urine, a diagnosis of Bright's disease, and a very gloomy prognosis was the consequence. Albuminuria and Bright's disease were usually regarded as but different names for the same disease, for a serious degenerative disease of the kidney. Now, all is different, and while the majority of physicians realize that albuminous urine does not necessarily imply kidney disease, yet there is a tendency among many, in their practice, to ignore this fact, and oftentimes to give a hasty diagnosis and prognosis, based upon the presence of albumen, and which the subsequent history of the case fails to substantiate.

Albuminuria may be the result of many causes, among which, for the purposes of illustration, may be cited a temporary congestion of the kidney, as from suddenly plunging into cold water (for a distinguished English authority has recently stated, that he believes that if the urine were examined immediately after coming out of an ocean bath, that of nearly every one would be found to contain albumen, a transient albuminuria being produced by action of the cold water on the body, determining the blood to, and causing a temporary congestion of the kidneys), faulty digestion, by which according to Semmola, the albumen of the blood, instead of being nutritious, is excrementitious, and is removed by the kidneys.

These two instances will suffice to point the statement with which, as has been said, we are already familiar, that albuminuria does not necessarily imply Bright's disease. What then, you may ask, does indicate degenerative kidney disease? We must answer, that the diagnosis of Bright's disease is, to-day, one of the nicest problems in diagnosis that the physician can have presented to him. There are no absolutely pathognomonic signs, since all of the usually accredited symptoms may be present when the disease is absent. We can, however, in very many cases form a fairly accurate opinion; but it would take much more space than we can afford, to clearly elucidate this question. In view of the increasing prevalence of this disease, of its insidious nature, of the difficulty of diagnosis, and of its subservency to hygienic laws, we know of no more important reading for the general practitioner than a good, recent work on this subject, for the views of to-day are altogether different from the views of ten years ago. The point that we wish particularly to emphasize, and to do so we will repeat, is that albuminuria does not mean Bright's disease, and that he who makes his diagnosis solely on this symptom will be repeatedly doomed to disappointment.

PIGMENTATION AND DISEASE.

One of the oldest divisions of the human race was that by color—the white, the yellow, the red, and the black varieties. To this day physiologists are not agreed as to the proximate causes of the variation in the amount of pigment deposited in the epidermic cells and in the hair. It is probable, as some have maintained, that it bears a definite relation to lung capacity; the more complete aëration of the blood in races of ample pulmonary development enabling them to throw off the carbon by the lungs, while in races of diminished lung power, notably the negroes, this carbon being retained is deposited on the surface of the skin.

Certain it is that a large group of diseases stand related in frequency and severity to the amount of pigmentation observable.

Quite recently Prof. ALEXANDER GRAHAM BELL has commented on this fact with reference to some nervous diseases. Deafness is more common among whites than among negroes. Many deaf mutes have a peculiar pallid complexion. Epilepsy is decidedly a disease of the white races. Even in lower animals this holds true. Mr. LAWSON TAIT and others have observed both epilepsy and congenital deafness in white cats, and only in such as are white. He adds: "Every kind of white animal I have kept as a pet has been the subject of epilepsy."

The general rule may be laid down that in white races, and in those members of dark races who become white—to wit, albinos—diseases of the nervous system and of the liver are more marked both in frequency and severity; while in dark races, the affections most common and fatal are of the lungs and bowels.

This rule is based on observed anatomical and physiological facts, such as the greater complexity of the cerebral convolutions in whites, the smaller lungs of negroes, their proportionately more active livers, the brevity of the intestinal canal, etc.

It would be interesting to collect further observations on this racial nosology. Though the literature on it is not scanty, it is as yet insufficient to enable us to explain the problems presented with satisfaction. In this country there is an unusually fine field for observation, as the three races are in many parts side by side under the same conditions of life.

THE M'GINNIS CASE AND PROFESSIONAL EXPERTS.

This case, which has been recently brought to a termination in this city, after a most protracted experience, is in some respects a noteworthy one. This man was condemned to death for the murder of his mother-in-law, and he has been hung under circumstances that do not seem altogether as they ought to be. His counsel recommended to the Governor of the State that the prisoner was of unsound mind, and requested a commission in lunacy to examine into and report upon his mental condition. Such a commission was appointed,

and upon it were two physicians who have extensive reputation as alienists, and among the balance one distinguished surgeon. After deliberating, the commission united (with one single exception) in saying to the Governor that they believed the prisoner of unsound mind. This one dissentient was, as we have said, a surgeon, whose only qualification to pose as an expert in such cases is to be found in the fact that he married the daughter of a distinguished alienist. The minority report of *one* was received and acted upon, the Governor refused to interfere, and the man was hung. Extended comment is unnecessary; he who runs may read how ridiculous this case must make the usual methods of expert testimony appear to any sensible person.

NOTES AND COMMENTS.

Neuropathic Plica.

This singular condition is well illustrated in a case reported by Dr. J. F. Le Page, in the *Brit. Med. Jour.*, January 26, 1884:

"J. H., aged seventeen years, consulted me on September 30, 1882. She stated that for six or seven days she had felt ill, complaining of more or less general numbness; and that, on September 29, she suffered the whole day from severe headache, which affected chiefly the brow, together with the sensation of 'pins and needles' over the scalp. In the hope of obtaining relief, she, in the evening, washed her head in warm, but not hot, water. After partially drying her hair, which measured three feet one inch in length, with a towel, she commenced combing it out on the left side, in the presence of her parents, who are intelligent and reliable people, and, whilst so engaged, she felt a tearing sensation on the right side of her head, as though the hair were being pulled out, and, on placing her hand to her head, found that it was being drawn up. In one or two minutes nearly the whole of this long hair on the right side of the head, was drawn into a hard lump. The parents, who witnessed this extraordinary phenomenon, spent a great portion of the night in a fruitless attempt to untangle the mass. The few hairs combed out were spread on her pillow while she slept; but afterwards most of them were found to be drawn up as before, although not tangled as was the larger mass.

On examination, I found the hair on the left

side of her head quite smooth, very slightly waved, and not in the least tangled nor drawn up. On the right side, extending to nearly the median line behind and to within an inch of the forehead, the whole mass was contracted to a hard tangled lump, which it appeared impossible to unravel. My patient's parents refused for some days to allow me to cut off the hair, as they, to use their own words, considered it 'a visitation from God.' On closer examination, I found that, under the superficial portion, the arrangement was strikingly peculiar, the hair being looped and festooned in a way which I might even describe as beautiful. Under the microscope, individual hairs appeared quite natural, but a very significant fact is brought to light; all the hairs which are contracted, closely curled, and intertwined, are, more or less, flat hairs, whilst those which are looped and festooned are round. Viewed without the microscope, it is at once evident that no dexterity could have produced the most remarkable condition—a condition which art could not produce. Menstruation commenced when she was sixteen, and was irregular until six months before she consulted me. Since that time she had not menstruated. Her appetite was fairly good; her habits were sedentary."

Puncture of the Aorta.

The following case possesses sufficient medico-legal interest to allow Dr. T. Pagan Lowe (*Brit. Med. Jour.*, March 8, 1884,) to tell it in his own words: "A few nights ago, I was called in haste to see a man who had been stabbed in a public house. I found the man dead, and learned from the bystanders that, about ten minutes before, he had been stabbed in the neck. Immediately on receipt of the blow, he exclaimed, "I am stabbed," and fell back into the arms of a man near him. He did not speak again, and died in about four minutes. On examination, I found a small triangular punctured wound situated on a level with the upper border of the sternum, just internal to the right sterno-clavicular joint; it measured three-quarters of an inch in one direction, and about half that in the other. A few drops of blood represented the whole of the hemorrhage that had taken place externally. At the necropsy the following day, I found that the weapon, which was a common pruning-knife, had taken a direction downwards and backwards, entering the thorax between the cartilages of the first and second ribs, notching the sternum. It had perforated both layers of the anterior fold of the right pleura, entered the pericardium on its

upper aspect, and penetrated the anterior wall of the aorta one inch from the valves. Blood had been poured out in huge quantities, filling the pericardium, and finding its way along the track of the wound into the right pleura, which it had about half filled. No other important structures were injured.

"The small amount of external hemorrhage is a notable feature in the case. It is easily accounted for. The skin-wound, owing to the direction of the blow downwards, was valvular, and retracted upwards as soon as the knife was withdrawn. Some impediment in this way was offered to the outward escape of blood; but the chief factor in its prevention was the laying open of the right pleural cavity, into which the hemorrhage had free vent. This latter circumstance would also tend to relieve the distension of the pericardium, and thus account for the length of time the patient survived such an injury."

Epithelioma of Penis; Amputation; Transplantation of Urethra through the Perineum.

As of interest in connection with the two similar cases that we have recorded, we note the following instructive case from the *Lancet*, January 12, 1884:

F. T., a baker, aged fifty-two, was admitted into hospital July 16, 1883. He declared that he never had any chancre or clap. Nine months ago he noticed a small tumor about the size of a pea on the under part of the glans, close to the frænum preputii. In a month's time the growth was as large as a hazel-nut, and he began to suffer from the most painful priapisms. Up to four months ago, he had been able always to uncover the glans penis.

The day following his admission, Mr. Storrey slit up the foreskin, and removed a growth about the size of an ordinary hazel-nut, together with a portion of the glans penis from the under side of the penis.

In a fortnight the patient was made an out-patient; but he presented himself in about six weeks' time with a return growth, and with some considerable infiltration of the penis. His great complaint was his terrible suffering at night from painful erections. There were no enlarged glands in the groin. Mr. Storrey, under ether, amputated the penis, after the method adopted by Prof. Thiersch, a short account of which is given in the May number of the *British Medical Journal* for 1878. The urethra was dissected out and transplanted through a hole in the perineum, and a drainage-tube was passed through the whole

length of the scrotum. Within twenty-four hours the scrotum filled with blood, which caused the stitches to give way, and, of course, delayed union. At the end of six weeks from the date of operation the patient was discharged, with the wound almost healed, passing his urine easily and comfortably through the hole in the perineum, to the edges of which the urethra was attached. Three months after the operation he appeared at the hospital to show himself, having gained in flesh, and feeling "a new man," as he expressed himself, declaring he had no pain whatever, and could pass his urine with great ease and comfort, although he was obliged to take down his trousers altogether to micturate.

Direct Pulmonary Therapeutics.

A foreign correspondent of a contemporary says that at a recent meeting of the Académie de Médecine, M. Sandras objected to treating bronchitis, laryngitis, and colds, by entrusting therapeutic agents to the stomach and intestinal canal. The drug thus administered is absorbed, passes into the circulation, and reaches the organs requiring treatment after a very roundabout journey, even if it do not lose its way there. M. Sandras recommends that the laryngeal and pulmonary mucous membranes be acted upon by direct inhalation of the vapor of turpentine and tar. The necessary apparatus consists of a bottle with a cork presenting two orifices. An India-rubber tube is passed through one of the orifices, with its end at a little distance above the level of the fluid in the bottle. Another tube is passed through the second orifice; this is in communication with the air, and is passed into the fluid. The bottle is half-filled with a mixture of chloroform, ether, and turpentine, or with 100 grammes of turpentine poured on to twenty grammes of Norwegian tar. The inhalations should take place three times a day, and be kept up for five minutes, at the rate of fifteen to twenty inspirations a minute. M. Sandras asserts that this treatment rarely fails to cure coughs, and all the unpleasant complications attending colds and bronchitis.

A Word Against Jequirity.

It seems that Parisotti and Galewski ("Revue d'Ophthalmologie," August, 1883,) have not succeeded as well with infusions of jequirity in the treatment of granulations as Wecker and others have. They obtained their infusion of the beans from the same pharmacist who furnished Wecker with his infusions; and they employed it with rigid regard to the directions given by

Wecker; but they produced only negative results. They noted the appearance of a completely smooth surface of the conjunctiva where the granulations had been, but at the end of two weeks the lids had almost regained their normal thickness, and the granulations had remained completely intact. If the conjunctival surface be examined before the swelling has entirely disappeared, there will be seen a united, almost glistening surface, resembling cicatricial tissue, but which is only caused by the swelling of the tissues. During this period the granulations remain concealed by the swelling of the mucous membrane; but, as soon as the inflammation has completely disappeared, the granulations will be found in their primitive state, without having undergone any modification. Moreover, they think that this method of treatment is not without danger to the cornea, which may be even entirely destroyed.

Turpentine as a Prophylactic in Infectious Diseases.

The *Med. Record* tells us that H. Vilandt writes in the *Ugeskrift for Læger*, vol. viii., No. 8, 1883, concerning the value of the oil of turpentine in the treatment and prophylaxis of diphtheria and the exanthematous diseases. He states that he has never seen any of these diseases spread from a sick child to other members of the family when this remedy was employed. In many of his cases no isolation could be attempted, as the mother was the only female in the family, and was obliged to take care of both the sick and the well, continually passing back and forth from one to the other. His method was to pour from twenty to forty drops of a mixture of equal parts of turpentine and carbolic acid into a kettle of water, which was kept simmering over a slow fire, so that the air of the sick-room was constantly impregnated with the odor of these two substances. He claims also that by this means a favorable influence is exerted upon the exudation in diphtheria, although it is by no means curative of the disease, and should never be relied upon to the exclusion of other remedies.

Examination of Fæces of Infants.

Dr. N. A. Randolph, of this city, has made some noteworthy observations on the fæces of starch-fed infants, and the fæces of infants after inunction of cod liver oil. On the former he reaches the following conclusions:

1. That many infants under three months can digest starch foods.
2. That the individual variations in this regard

are so numerous that no broad and general statement can be made as to the period at which infants *begin* to digest starches ; and,

3. That the physician can be absolutely certain that a farinaceous ingredient in the diet of a young infant is beneficial, only by an examination of the dejecta under such diet.

Of inunction he found that in eighty per cent. of the cases a notable increase of the fatty matters passed per anum was observed after the persistent inunction of cod liver oil. In the remaining twenty per cent. the quantity of faecal fats was unaltered by the treatment, and in one case remained negative throughout.

Social Relations of Inebriety.

Some conclusions on this subject reached by Dr. Crothers, of Hartford, are as follows :

1. Inebriety as a disease was noted in antiquity, and has ever been considered a form of insanity, marked by a progressive march or order of events, from certain physical causes, on to death.

2. The march of inebriety is in waves and currents, controlled by some unknown law, clearly within the range of a wider knowledge to prevent and remedy.

3. The treatment of inebriety by penal methods is disastrous to the victim, actually intensifying and making the disorder more incurable.

4. Physical treatment and isolation in special work-house hospitals, where the best conditions of physical and mental health can be applied and maintained for a long time, give the largest promise of cure and permanent restoration, and are the means suggested by nature and scientific study.

5. As a question of economy simply, it would be an immense gain to the tax-payer and society to thus quarantine these persons, and make them self-supporting. This is a fact whose practical character is well assured in many ways.

Typhoid Fever Complicated by Nephritis.

An interesting case from a diagnostic standpoint is that which Mr. Milnes reports in the *Brit. Med. Jour.*, February 16, 1884:

A nurse, who had been nursing cases of typhoid fever, was admitted into Addenbrooke's Hospital, suffering from high fever and pain across the loins; her urine was scanty, thick, and bloody, highly albuminous, and contained casts. There was no drowsy. She said she thought she had caught cold during a catamenial period a week before, and ever since had suffered from languor, feverishness, and pain across the loins. Five days

after admission, a copious eruption of typhoid spots appeared, and for several days there was moderate diarrhoea. The fever ran a rather short course, and the albumen gradually disappeared from the urine.

Artificial Food for Children.

There has been great discussion as to the qualifications of condensed milk as a substitute for the human article. Some men strongly advocate its use, while others bitterly condemn it. After reporting a case of infantile scurvy, in a foreign exchange, Dr. Edmund Owen says :

"The opinion which I have been compelled to form in my work in the out-patient rooms of the Children's Hospital, is that the worst nourished of the hand-fed infants are those that have been reared upon condensed milk and the various patent food stuffs; and that whenever an infant cannot have human breast-milk, the best substitute will be found in fresh cow's milk prepared and administered *secundum artem*."

The Absorptive Power of the Skin.

Since drugs are frequently used by inunction, it will be interesting to read that from experiments made with salicylic acid, salicylate of sodium, and tincture of iodine, applied to the skin as simple solutions or in the form of spray and with mercurial ointment, Dr. Ritten (*Deutsch. Archiv. für Klin. Med.*, p. 143, vol. xxxiv.) comes to the conclusion that the normal skin has not the power of absorbing these substances either in a fluid condition or in the form of ointment or of spray, but that all substances which irritate the skin may produce, when sufficiently vigorously applied, a solution of continuity, and may then be absorbed from the altered skin.

The Value of Internal Œsophagotomy.

Stricture of the Œsophagus has hitherto been usually ranked among that class of ailments for which little could be done. Dr. Henry B. Sands has an article on the subject in the *N. Y. Med. Jour.*, February 23, 1884, which thus concludes :

On reviewing the whole subject, we may conclude that certain forms of Œsophageal stricture, which have heretofore proved unmanageable, are no longer beyond the reach of surgical art; and that in some of these, the internal Œsophagotomy is capable, not only of saving life, but also of re-establishing the function of deglutition, so essential to its enjoyment.

Relapsing Fever Complicated with Small-pox.

In the *Ejened Klin. Gazeta*, 1883, May 15, Dr. B. P. Brajnikoff publishes a case in which a patient, aged eighteen, admitted for relapsing fever, during the fourth relapse of the latter developed all the signs of small-pox. Microscopical examination of the blood after the appearance of variculous rash showed the presence of Obermeier's spirilla. The small-pox took its usual course. The patient recovered.

SPECIAL REPORT.

PROGRESS OF OTOLOGY.

BY LAURENCE TURNBULL, M. D.

Fatal Suppuration of the Middle Ear, and Hemorrhages from the Ear.

Hassler (*A. f. O.*, vol. xviii.) has collected twenty-one cases of injuries of the carotid artery in its passage through the carotid canal of the temporal bone. Thirteen of these cases were of suppuration of the middle ear, terminating fatally from erosion of its walls; and of the other eight cases there was serious, and in some of them fatal hemorrhage, one of which occurred in his own practice. At the post-mortem examination in his case, a portion of the carotid canal adjoining the tympanic cavity, was carious and defective. The destruction was associated with spreading caries of the temporal bone, and the osseous gap in the carotid canal was still occluded with sequestræ. (A similar condition existed in a case which I presented at a meeting of the Philadelphia County Medical Society.) The aperture in the softened arterial wall was found at the spot where the course of the vessel passed from the vertical to the horizontal direction.

Boke (*Archiv für Ohrenheilkunde*, vol. xx., p. 47) has reported two additional cases, in which there was fatal hemorrhage—in one from the bulbus venæ jugularis; in the other, from the sinus petrosus inferior.

Cases of serious hemorrhages from the large vessels in the vicinity of the tympanum, which terminated fatally, are fortunately rare, and are generally the result of long-continued and improperly-treated otorrhœas. They are found in scrofulous and tubercular individuals.

I have seen and treated a number of cases of serious hemorrhages from the ear following severe blows or falls upon the external ear and face. In one recent case the hemorrhage was caused by a fall upon the chin, in which profuse bleeding took place from both ears without apparent per-

foration of the membrana tympani. My usual course of treatment has been injections of ice water and powdered persulphate of iron, hypodermic injection of ergotine, or the mixture of acid tannic with gallic acid of "Mackenzie" given internally. When these means fail, digital compression of the carotid is maintained, or, as a dernier resort, ligature of the carotid.

The following is an interesting and instructive case of another form of hemorrhage from the ears: I was called to see Mrs. Hannah N., aged thirty-three years, on April 14, 1883, and found her to be a delicate woman, who had suffered from disturbance of the heart and kidneys when a girl, but who had since never entirely recovered therefrom. After marriage, she had conceived and borne three children, only one, however, living. The fœtus in the present instance had been dead for some time, and considerable force had been employed in the delivery, with great pressure upon the abdomen, and exposure. She recovered to a degree from the miscarriage, but suffered from sick stomach, pain in the region of the liver, difficulty of breathing, and, not regaining strength, was anemic and feeble. Early in March, 1883, she had an acute attack of "gathering in her head of both ears" (otitis media purulenta), which was followed by a discharge of blood—at times quite profuse, and then again a continuous oozing, which had kept up since the eighth of that month. The blood was most of the time of a bright color, but at intervals mixed with pus.

The previously attending physicians had plugged the ears, and the following was the condition when I visited the patient: Blood was escaping through the dilated eustachian tubes into the naso-pharynx, which was accompanied by fainting attacks. She had at three different times fainting, with convulsive attacks. However, not to anticipate, when I examined her, the pulse was very feeble, respiration rapid and irregular, face yellowish, abdomen sunken, and no tumor present except some enlargement of the liver. Her mouth was full of clotted blood, part of which she removed by her fingers or had it wiped out, but the majority must have been swallowed and afterwards vomited in the form of partly-digested blood mixed with bile. The diagnosis as received from two physicians not of our faith was *malignant disease of the stomach*.

The following is a report of the autopsy upon the body of Mrs. N., performed by my assistant, Dr. L. W. Steinbach: The body presents a somewhat emaciated appearance, subcutaneous adipose tissue being rather scanty, but the muscular

structure not extensively wasted. The abdominal parietes present a greenish, livid discoloration. There exist pleuritic adhesions of the left lung's apex anteriorly, and the lower lobe postero-laterally, but none of the right lung. The structure of both lungs is normal, with the exception of a very limited tubercular deposit in the right apex. The heart occupies a normal position, is considerably and uniformly hypertrophied, its auricles empty, and each ventricle containing a large clot of apparently freshly-formed fibrin.

The omentum had a yellowish-green color. The intestines were moderately filled with gas and greenish-yellow liquid feces. The stomach was moderately distended, and its walls thin, discolored, and not congested. It contained about a pint of reddish-brown liquid, of the consistency of thick cream—apparently partly-digested blood mixed with gastric juice. The liver is slightly enlarged and greatly discolored on its posterior surface by bile pigment; its structure being apparently normal. The gall bladder was large and full. The spleen had twice its normal size and weight. The right kidney, larger than usual, presented otherwise a healthy appearance. The left kidney being atrophied, with its cortical and medullary substance disappeared, only the collapsed (not contracted) investing capsule, the pelvis, and other fibrous structures, remaining.

Her bladder was normal, but the uterus bore at its os the cicatricial marks of former ulceration. The ovaries were markedly enlarged, having the dimensions of a laage-sized peach-stone. The left fallopian tube remained impervious, but in other respects the uterus and its appendages presented nothing abnormal.

The brain was not examined. The temporal bone on the right side being forcibly removed for examination, caused a breaking or tearing off of the carotid artery from the carotid canal, and the condition of this vessel could not therefore be ascertained. The middle ear and the external auditory canal contained some dried blood. The upper two-thirds of the tympanic membrane were destroyed, leaving a crescent-shaped segment below intact. A portion of the handle of the malleus was wanting, though not broken off (by manipulation), though otherwise the ossicula were intact. There was no sign of caries or necrosis of any part of the temporal bone. We would therefore class this case as one of a true otitis media hemorrhagica, and the blood may have come from one of the sinuses.

—In Vienna, in 1882, there were 16,605 births in wedlock, and 12,657 illegitimate.

CORRESPONDENCE.

Salicylic Acid in Cerebro-Spinal Meningitis.

EDS. MED. AND SURG. REPORTER:—

I see in your issue of the *REPORTER* of March 8, 1884, page 313, an article with the above caption, taken from the *St. Louis Courier of Medicine* for February, 1884, in which my name is referred to by Dr. D. C. Ramsey, as "verifying his good success with salicylic acid in the treatment of cerebro-spinal meningitis." The facts are as follows:

I took Dr. Ramsey in as a one-fourth partner, in the autumn of 1880, for one year—he being then in his twenty-second year of age, and having had six months' practice, while I had been established here as a practitioner for over twenty years. During the winter of 1880-81, we had cerebro-spinal meningitis in an epidemic form.

Toward the very latter end of the epidemic, being struck with the frequent and sudden metastasis (or apparent metastasis) from the head and neck, to one or more of the larger joints, thinking the investing membranes of the brain and spinal cord were of much the same character as the ligaments and coverings of the joints, that the pain in cerebro-spinal meningitis was of the same acute degree as in inflammatory rheumatism, that as the intense pain subsided the effusion came on as in joints affected by rheumatism, I could not resist the thought that there must be, to say the least of it, a great similarity in the two diseases; and consequently if salicylic acid was anything approaching a specific in acute rheumatism, it should do good in cerebro-spinal meningitis. These reflections I communicated to Dr. Ramsey and Dr. E. V. Spencer, of this place, at the time, also to Dr. Wm. M. Holton and Dr. McDonnald, of New Harmony, Ind., saying that my convictions were so deeply rooted, that if another opportunity offered I should certainly make the trial.

At that time I did not think, by Dr. Ramsey's actions and Dr. Spencer's words, that either of them were of my way of thinking, and was very much surprised when Dr. Ramsey, last fall, read a paper "On the Use of Salicylic Acid in Cerebro-Spinal Meningitis," (since no other epidemic of the disease has occurred in his practice), before our little county medical society.

Since I first thought of trying salicylic acid in this disease, I have had but a single opportunity, and of course that was sporadic. This case was a German boy, fourteen years old. After an efficient cathartic, I gave him salicylic acid in solution with carbonate of ammonia and bicarbonate of soda, in fifteen-grain doses every three hours. Several doses having been given without, as far as I could see, benefiting him, I increased the dose to thirty grains every three hours. This seemed to have the desired effect, so I ordered the dose back to fifteen grains, extending the time to six hours. During the following day the symptoms became aggravated, when I again returned to the half-drachm doses. After three or four doses of that amount, he seemed much improved, and was returned to fifteen-grain doses every six hours.

From this time on he made a steady and rapid recovery on the fifteen-grain doses every six hours. One case, and that not during an epidemic, simply does not prove anything. Now, I am not alto-

gether in favor of one person "stealing another's thunder," and I am utterly opposed to stealing a man's thunder when he really has none to steal.

I consider the remedy entirely untried. What its effects may be during an epidemic, I deem perfectly problematical, trusting a sufficient number of the profession may think it worthy of investigation.

Too many, frequently those who have only been engaged in practice a short time, have to air themselves by appearing in print; and frequently by seeming worth, cause us to have to clear away such an immense amount of rubbish to get so little of worth or fact.

What we want are *candid* writers, with *practical* articles, based on a *thorough* experience, and not simply to have their names sounded abroad in the land; there certainly should be a higher ambition than that.

JOHN B. WEIVER, M. D.

Mt. Vernon, Ind.

Blood-letting vs. Morphia in Puerperal Convulsions.

EDS. MED. AND SURG. REPORTER:—

The following case of puerperal convulsions may be of interest to the profession from the two remedial agents applied:

On the 21st of February, at 6 p. m., I was called to see Mrs. L., aged twenty-five, primipara, pregnant at full term; found patient vomiting; complained of pains incident to labor. Upon examination, found os undilated and rigid; pulse 100. Within a few moments, she was seized with a severe convulsion. As soon as practicable, gave R. potass. bromid., gr. x.; chloral hydrate, gr. x., which was immediately thrown up. Sent for Dr. Henry; then gave, hypodermically, R. morphia sulph., gr. $\frac{1}{2}$. In one hour she had another convulsion, followed by same treatment, and continued to have them at same intervals, followed with same treatment, until the fourth convulsion occurred. At this period, there was no change of circulation (100), no progress in labor apparent, pupils contracted, skin moist, with profound sleep, which continued twenty-four hours from time of first convulsion. Then she aroused at short intervals, complaining of pain in back and uterus. Upon examination, found her in first stage of labor, which progressed nicely without anesthetics or opiates. At 9 p. m. a still-born boy, of medium size, was born. Gave R. fl. ex. ergot in latter end of second stage; uterus contracted, with little hemorrhage—probably too little, as the sequel may show. Applied bandage, and within one hour, having other patients requiring my attention, I left her with Dr. H.

Patient rested quietly for five hours after delivery, when she was seized with a violent convulsion. I was summoned at once to return. Arrived in two hours after paroxysm; found doctor (not being equipped with a hypodermic instrument) had taken thirty ounces of blood from her arm. Circulation 100. Patient remained quiet by the aid of a few inhalations of chloroform upon any indication of emotion throughout the following day. Patient made a good recovery.

Now, the question may arise, should blood-letting have been the proper treatment after the first convulsion? If we had had the assurance

of controlling the third stage of labor properly, blood-letting appears to have been indicated, and might have prevented a recurrence of them. The convulsions evidently were of a nervous character. Orient, Iowa. H. V. MONNETT, M. D.

Salicylic Acid in Cerebro-Spinal Meningitis.

EDS. MED. AND SURG. REPORTER:—

GENTLEMEN: In your journal of March 8th, I notice a comment on the use of salicylic acid in treatment of cerebro-spinal meningitis, by Dr. D. C. Ramsey, which prompts me to give my short experience with the remedy in that dread disease.

February 20, 1883.—I was called to see a very acute and severe attack of cerebro-spinal meningitis. The patient was a German boy, ten years of age; good constitution, strong and healthy. With quinia, bromide of potassium and gelsemium, I reduced the high fever in twenty-four hours; but the intense pain and suffering still remained. Having had good success with salicylic acid in acute rheumatism, the thought occurred to me: Why will it not be good in this case? Having never heard or read of salicylic acid being used in cerebro-spinal meningitis, I was a little careful in beginning the use of it. But thinking my patient would surely die any way, I determined to try it; and with from ten to twenty grain doses every six hours, I controlled the pains and gave my patient comparative ease. The rigidity of the muscles of the neck and back became less marked, and at times completely relaxed.

Fearing serious results from too prolonged administration in the young subject, I suspended the use of it, and immediately all the pain with intense suffering returned. Again I gave the salicylic acid, and my patient got quiet and slept for hours. I repeated this several times in the course of two weeks, with the same results. In the meantime, Dr. B., a very eminent physician, with an extensive experience in cerebro-spinal meningitis, was called in consultation. He marveled at the relief that the salicylic acid gave, but did not altogether approve of its administration. Nevertheless, I continued to give it at intervals, as it seemed to give more relief and do more good than anything else I could give, or rather did give.

He made a complete recovery in about twelve weeks, without any of the bad consequences that generally follow a majority of the severe cases of this disease.

The frontal headache, noises in the ears, etc., claimed by some from the use of salicylic acid, were not observed in this case, but *vice versa*. When he was screaming loud enough to be heard into the street, with pain in the head and noise in the ears, a full dose or two of salicylic acid would calm him down and give him some rest.

I will also mention that the quantity of urine voided when he was taking the salicylic acid was twice as much, or nearly so, as when he was not taking it.

Unfortunately, I took no notes in this case, consequently cannot report it as minutely as I would like to, but hope to learn and hear more of this remedy in the future.

J. CHEWNING, M. D.

Renault, Ill., March 13, 1884.

NEWS AND MISCELLANY.

Transactions of the Medical Society of Virginia, Fourteenth Session, 1883.

This Society has four hundred and forty-three members, of the fifteen hundred regular practitioners of the State. Of this number there is about an average attendance annually of one hundred.

The annual address to the public and profession was by I. Edgar Chancellor, M. D., on "Mineral Waters." This subject was also presented by M. G. Ellzey, M. D., on "The Therapeutic Value of Rawley Water," and by A. M. Fauntleroy, M. D., on "Medicinal and Therapeutic Properties of Rockbridge Alum Waters."

These several papers are interesting and exhaustive, and will contribute to direct the mind of the profession beyond our limits to the great value of the mineral waters of Virginia. For several years, the Society has in vain sought such information from committees.

Report, "Obstetrics and Diseases of Women," M. G. Ellzey, M. D., Washington, D. C. This paper strongly commends the adoption of the principles of Lister in obstetrical practice, and the observance of scrupulous purity in the lying-in chamber. The author deprecates the use of iron styptics, and Monsel's solution to relieve flooding, and prefers tannin, alum and ice. As to the relative advantages of home and hospital treatment of chronic uterine diseases, the craze after specialism is considered to have gone as far as the profession should sanction, otherwise this practice may degenerate into a bold system of advertising quackery. The author rightly maintains that unmarried females should not always be subjected to vaginal explorations in ordinary cases of dysmenorrhœa; the pessary, he pronounces to be a great-abused instrument, sometimes inducing ulceration, and even blood-poisoning. The report concludes with a warning as to the danger of the protracted use of opiates and alcoholic stimulants, resulting sometimes so disastrously to women of high social position, and inducing conditions of psychological disease and of morbid erotism.

Report on "Disease of Children," by Wm. H. Coggershall, M. D., is excellent. The suggestion of Dr. Denar, of London, as to the value of fluid extract of ergot in four to fifteen minim doses every three hours for the relief of whooping cough is endorsed. In cases of cholera infantum, ice-water injections, cold compresses to the abdomen, and internally, a cream of subnitras of bismuth, are recommended; also for *infantile convulsions*, bromide of sodium, one grain well diluted in a teaspoonful of water given every fifteen minutes; and for cancrum oris and aphthous sores, the local application of subnitras bismuth often repeated, with the usual disinfecting wash and supportive treatment.

Report on "Chemistry, Pharmacy, Materia Medica and Therapeutics," by A. M. Fauntleroy, M. D. Compressed discs for hypodermic use, as prepared by Wyeth & Bro., are commended to the trial of physicians as excellent and convenient forms to administer the salts of morphia, atropine, etc., which are rendered soluble by mixture with

sodium chloride, or sulphate. *Convallaria majalis*—lily of the valley—in the form of tincture, Dr. Fauntleroy considers a valuable cardiac stimulant and tonic, free from the cumulative syncopal action of digitalis, though inferior in diuretic properties to the latter drug. The author concludes with the practical remark that "the earnestness displayed in the search for new remedies, and the critical testing of them by physiological methods, will tend to add to the resources of the healing art."

Report on "Medical Practice," S. K. Jackson, M. D. Dr. Jackson claims that during the present century epidemics of plague, Asiatic cholera, typhus or jail fever, and scurvy, to which list might be added yellow fever, have been arrested or prevented, and human life lengthened, and our ideas of the causation and the prevention of disease have been revolutionized. This report embraces the actual treating of diseases, especially those of germ origin. Quinine is the first-mentioned germicide, and is used to antidote and neutralize the sedative power of malarial poison; second, the various forms of mercury for the destruction of organisms productive of the suppurative processes of syphilis and phthisis pulmonalis; and, also, soda-bisulphite for the arrest of pulmonary abscess, the "modus operandi" of the latter being suggestive of the law that "no organism can live in the effete products of its own life, in its own excreta."

Second, there is a brief consideration of the chemical treatment of such diseases as cholera infantum, rheumatism, gout, and calculi, and finally is noticed Koch's great discovery of the existence of a parasitic organism in the tubercle of phthisis pulmonalis—a disease causing one seventh of the deaths of the human race. This parasite belongs to the rod-shaped bacteria. This interesting paper concludes with a tribute of praise to army and naval medical officers, "whose labors have already resulted in a marked decrease in the death-rate on shipboard and on land, due to improved sanitation and methods of the treatment of disease which have been suggested by modern science and by disinfection."

Reports on "Ophthalmology," are furnished by Charles M. Shields, M. D.; "How Shall We Remove Foreign Bodies from the Ear," by Julian J. Chisholm, M. D.; "Plastic Surgery of the Face," by L. McLane Tiffany, M. D.; "Injuries of the Eye," by Joseph A. White, M. D.

In a paper by W. C. Dabney, M. D., the bacillus tuberculosis question is briefly discussed. The theory of Koch that bacilli are only found in tubercular or caseous deposits, and are the essential and specific cause of tuberculosis, the author does not, as yet, consider fully established. If they were, it might be expected that nurses and attendants in hospitals for consumptives would contract the disease by inhaling the germs, which does not occur by experiments made at Brompton, Eng. A damp atmosphere and scrofulous habit, however, present the predisposing causes; and the presence of bacilli in the lungs, or other diseased organs, contributes to hasten the advance of the morbid process. The antiseptic and germicide treatment of tuberculosis is omitted. The chairman of the Committee on Hygiene, W. F. Barr, M. D., deploras in his report that the Legislature

of Virginia has refused to enact a statute regulating the practice of medicine in the State, and that the Board of Health has virtually become a nullity.

The subject for general discussion was Diphtheria, during which a valuable paper was read by Bedford Brown, M. D., of Alexandria, entitled, "Reminiscences of personal experience in the history of Diphtheria," covering a period of thirty years' time, and commencing in 1856. The distinguished author, whose opinions on surgery and medical practice have been favorably commented on abroad, urges the importance of the maxim of the sagacious Watson, viz., "Study constantly the tendency and mode of death:" this precaution, he adds, is of vital consequence in nearly all cases of diphtheria, since the danger may occur from septicæmia, uræmia, or paralysis of the reflex system of nerves, or from paresis of the organic system of nerves, resulting in an early and rapid decline of the strength of the heart's action, and of the corporeal temperature below the normal standard. Such signs the author of this paper asserts do not occur in cases of membranous croup. In the latter affection the temperature is high, and there are no indications of septicæmia, or typhoidism, whereas in diphtheria there is a decline of temperature after forty-eight hours, and proofs of blood-poisoning causing mal-nutrition and vital depression, with membranous deposit on the mucous surface of the conjunctiva, the vagina or rectum;—the infective poison expends its action on the various ganglia of the sympathetic and vaso-motor systems of nerves of the heart, lungs, and stomach.

In the necrological column of the Transactions is a notice of the death of W. O. Hill, M. D., of Woodstock, Shenandoah county, Va., adding another sad example to that of Dr. A.'s case, of Ellentown, N. Y., of the reckless use, even by physicians, of potent anæsthetic drugs. Dr. Hill, it appears, instructed his wife to bring to his bedside an ounce vial of chloral, and to pour the crystals into her hand, telling her when the dose was sufficient. This quantity was dissolved in water and swallowed, and in one hour caused death. The remnant of chloral in the vial showed that the victim had taken 120 grains.

Among the delegates-elect to the approaching session of the American Medical Association in May, are Drs. James L. Cabell, R. S. Payne, Hunter McGuire, Landon B. Edwards, and Frederick Horner.

The New Paris School of Medicine.

In the new School of Medicine now being erected at Paris, it is intended to provide unusual library facilities. Indexes of all the works in the library, representing about 60,000 volumes, are being prepared—one an alphabetical list of authors, and the other an alphabetical list of titles. It is also proposed to keep a register of all legally-recognized practitioners of medicine throughout the world. A preliminary investigation has shown that such a list would comprise about 193,000 names, namely, 65,000 in the United States, 26,000 in France, 32,000 in Germany and Austria, 35,000 in Great Britain and colonies, 10,000 in Italy, 5,000 in Spain, etc.

New Instruments.

As a matter of general interest, we insert a description of some new instruments manufactured by John Reynders & Co., of New York.

The illustration shows the speculum as now perfected after a long series of trials. The new speculum has an Archimedean screw at (A), by

so far short in answering its purpose as to seriously interfere with the usefulness of the instrument. At (B) there is another screw by which the width of the blades from each other is changed. The square plate at (C) rests upon the sacrum, while the looped band goes around the shoulder of the patient over her clothes; the end of this band has

Fig. 1.

DAWSON'S MODIFICATION OF ERICH'S SPECULUM.

which the blades can be moved forward and backward very conveniently; the mechanism in the place of this in the original Erich speculum falls

button holes, by which, when the blades are introduced, the speculum can be made firmly self-retaining. This speculum, as now perfected, en-

Fig. 2.

ables the operator to dispense with the assistant or nurse who would have to hold a Sims' speculum; the vaginal walls and uterus cannot be displayed any better by any means known than by its correct application.

Figures 2 and 3 show Dr. Swinburne's Mouth Gag with Retractor, and his Polypus Forceps.

These instruments have been devised for the removal of abnormal posterior nasal and pharyngeal growths. The mouth-gag serves, of course, for holding open the mouth, and the retractor attached to it to draw forward the uvula and soft palate. Thus the walls of the posterior nasal and pharyngeal space are distended and brought in the most favorable condition for seizing the growths with the polypus forceps, particularly successfully constructed for its peculiar use. In the hands of many, these instruments have caused a most agreeable surprise by the simplicity and efficiency of the method of use they are intended for.

Fig. 4.

Fig. 5. A new pocket hypodermic syringe. The top illustration shows the entire instrument put together; the right end is the syringe itself, having a glass barrel and surrounded by a metal casing; to its left end a series of seven compartments are attached for holding hypodermic pellets. The instrument is so arranged that if desired but one of the compartments can be attached. It is then so compact as to be easily carried in the vest pocket.

Fig. 6. A new ear-syringe, by which a continuous injection can be made without removing the instrument from the ear. The piston-rod is surrounded by a coiled spring, by which the same in its natural position is held as though withdrawn to the rear end of the barrel. By grasping the syringe as indicated by the rings attached to it, and pushing in the piston-rod, which latter is hollow, the soft rubber tube, with its sucker, being placed in a basin with water, the syringe will become filled; releasing pressure upon the piston-rod, the coiled spring will push it back and the water pass through an opening in the piston controlled by a valve, to the other side of the lat-

Fig. 3.

ter. When the piston is again pushed in, the water in front of it will be ejected, while at the same time an additional supply will fill it to the back of it from the basin. In this manner the

Fig. 5.

Fig. 6.

Fig. 4. A new nasal speculum by Callen, of Paris. Its advantages are obvious. operation of injecting with this syringe can be continued *ad libitum*.

South Carolina Medical College.

The annual commencement of the Medical College of the State of South Carolina was held March 1 in the presence of a large and cultured audience at the Academy of Music, in Charleston.

The degrees were conferred upon the following graduates by General B. H. Rutledge:

In Medicine.—N. Yancy Alford, Simon Beckham, William D. Bratton, R. Andral Bratton, John W. Corbett, H. L. Culbertson, J. D. S. Fairy, James E. Fales, W. N. H. Folk, B. W. Hunter, Archibald McIntyre, Joseph F. McKay, G. Augustus Neuffer, Mazyck P. Ravenel, Howard Reedy, B. Frank Smith, J. Houseal Thompson, Charles E. Wideman.

In Pharmacy.—Messrs. F. W. Schwettman, first honor; A. P. Aimar, J. A. Barbot.

The College prize, a handsome silver goblet, was then presented to Dr. M. P. Ravenel by the Hon. Wm. A. Courtenay, Mayor, who, in making the presentation, alluded to the College as being identified with the highest educational interests of the State and city, and who, in closing, said: "A reward of merit from such a source is indeed a prize, and I congratulate you upon having secured it. May it ever be to you an incentive to continuous exertion in your noble profession, and may you win its highest honors."

The annual address to the graduates was then delivered by ex-Attorney-General LeRoy F. Youmans. The address was a finished and scholarly exposition of the philosophical features of the science of medicine, and abounded in rich classical allusions and stirring rhetorical figures. It was calculated in the highest degree to impress upon the young graduates the duties and responsibilities which would attach to them in the profession they had chosen for their life-work, and was delivered with all that fervid eloquence which characterize the orator, and never fails to engage the rapt attention of his audience.

The valedictory address was then delivered by Dr. R. Andral Bratton, of Rock Hill. The address was well delivered, and included a chaste and fitting tribute to the memory of Dr. J. Marion Sims.

The exercises were closed with the benediction. During the interludes, Metz's Band added to the attractions of the entertainment by discoursing choice musical selections. There are few occasions of the kind in Charleston which are more popular than the commencements of the Medical College, and the pleasure and interest of the large audience was manifested by frequent applause and the generous offering of a wealth of floral tributes to the graduates.

Doctors on the Witness Stand.

The Hon. Will Cumback, in an address at the recent commencement exercises of the Medical College of Indiana, related this bit of personal history:

"The very last case I had in court as a lawyer some years ago was a suit against a doctor for malpractice. The witnesses were nearly all physicians, and they kindly took possession of the case. The plaintiff and defendant were soon lost sight of, and the issue was soon changed to a contest between the allopathic and eclectic systems of

medicine and surgery. The court-room became blue from the firing and explosion of the most immense technical terms from those men of science. The jury became so bewildered and dazed that they brought in a verdict of but one cent damages for my client, and failed to make any finding whatever as to the merits of the allopathies and the eclectics, so that the people of my county are still in doubt which is the best—some are for one and some for the other. I became so desperate that I accepted an office under the government, and will never return to the practice of law unless driven to it by sheer necessity."

Dr. Yandell.

Two singular and pathetic incidents are connected with the death of Dr. L. P. Yandell, the late chief editor of the *Louisville Medical News*. He sent word to the printers to reserve space on the editorial page of the issue of March 15, for some special matter that he would send to them. What he intended to publish there no one will ever know, for in the reserved space was announced his sudden and untimely death. The other incident referred to is as follows: On the day of his death he called on a physician, and, the subject of chloral being mentioned, he told his friend of a case that had come under his notice. A patient suffered much from trouble with his heart, and while suffering severely, summoned Dr. Yandell. Dr. Yandell administered a dose of chloral, which he assured his patient would relieve him. It did some good for a few moments, but then the patient fell back in his chair and died. It was, said Dr. Yandell, in speaking of the case, too sudden for the chloral to have produced the death, and the man had simply died of angina pectoris, or paralysis of the heart. In describing this case to his friend, Dr. Yandell imitated the actions of the dying man, falling back in his chair, and throwing his arms about. A few hours later, and under the same circumstances, he himself breathed his last.

Practical Chemistry in the University.

The Trustees of the University of Pennsylvania intend organizing a new department of pure and applied organic chemistry in connection with the Towne Scientific School, as soon as \$100,000 is placed in their hands for the purpose. Since the establishment of the Towne School there have been numerous applications on the part of chemical students for instruction in applied organic chemistry, together with practical work in the chemistry of those raw materials or finished products in which the applicants have been particularly interested. The University has been unable to meet the demand, since the laboratory at present is exclusively devoted to inorganic or mineral chemistry. As there is no other school of science of the same scope as the Towne School in the vicinity of Philadelphia, the trustees feel that the community has a right to look to them to supply a need if it be shown to exist. H. H. Houston has started the subscription list with a donation of \$10,000.

For the laboratory work, a building will be erected at the southeast corner of the University grounds.

Religious Mania.

The *Allgemeine Medicinische Central-Zeitung* states that a sect of persons has been discovered to exist at Rostov, in Southern Russia, who kill children by narcotic poisons, in order to keep them from earthly suffering, and secure them at once heavenly joys. The people are the victims of a religious madness.

If these people would control their own animal passions, so that these children would not be brought into the world, then the same ultimate result would be accomplished, and in a less censurable manner.

OBITUARY NOTICES.

CASPER MORRIS, M. D.

Casper Morris, M. D., a well-known physician, died March 16, in the 79th year of his age. He was born in this city, and his ancestors resided here since the founding of the colony by Penn. He graduated from the medical department of the University of Pennsylvania in 1826, was resident physician of the Pennsylvania Hospital, and practiced his profession until 1871. He was an eminent lecturer, and contributed liberally to medical works, among his publications being a valuable volume on scarlet fever.

Items.

—The centennial anniversary of the General Hospital at Vienna is to be celebrated in June next.

—The Miami Medical College held its annual commencement at Cincinnati on March 6, graduating a class of twenty-seven.

—The Detroit Medical College held its annual commencement on February 29, graduating a class of twenty-five.

—The Michigan College of Medicine, of Detroit, held its annual commencement on March 3, graduating a class of twenty-seven.

—In the *Am. Jour. Med. Sci.*, January, 1884, Dr. G. C. E. Weber reports a case of elephantiasis arabum cured by ligature of the femoral artery.

—Sponging the surface of the body with a solution of quinine in alcohol—one drachm to the pint—is now recommended for excessive sweating. It is a remedy that has long yielded us good results.

—It is reported that a new medical college has been organized in Cincinnati, under the title of the "Medical University of Ohio." This will make the fourteenth medical college in the State of Ohio.

—Another death from ether is reported in the *Brit. Med. Jour.*, the victim being a laboring man, fifty years of age, who was being operated upon at the Gloucester Infirmary for cancer of the gums and throat.

—The Medical Department of the University of Buffalo held its annual commencement on February 26. Degrees were conferred upon sixty-two graduates. The address to the graduating class was delivered by Dr. Roswell Park.

—The Medical College of South Carolina held its annual commencement on March 1, graduating twenty students in medicine, and three in pharmacy. The College has established a graded course of three years.

—The treatment of syphilis without mercury is well enough in theory, but does not work in practice. Such is the conclusion arrived at by Prof. Newman, of Vienna, as the result of a series of cases treated in both ways.

—At a meeting of the Faculty of the Medical Department of the University of Georgetown, D. C., held March 13, a committee of three was appointed to report a plan for the procurement of a suitable building for college purposes.

—A bill entitled an act to appropriate a sum of money to enable the Baltimore Medical College to equip and maintain a hospital, to be known as the "Maryland Infirmary and Lying-in Hospital for Indigent Women," has been introduced into the Senate of Maryland.

—The following placard hangs in a Tennessee store-window:

Peppermint Ile for
Hed ake
Bellee "
Tooth "

—During the academic year 1882-83 six hundred and seventy-two M. D. degrees were conferred in France. Not far from three-quarters of the whole number, or four hundred and sixty-five, were conferred by the Paris faculty. Montpellier comes next, with sixty-nine; then follow Bordeaux with forty-six, Lyons with forty-three, Nancy with twenty-one, and Lille with twenty.

—The soap weed, which grows abundantly in Colorado and New Mexico, is coming to the front as a superior material for the manufacture of paper. Experiments, it is reported, have demonstrated that from the fibre of the soap weed a paper equal to the finest linen may be produced; and as the weed grows in immense quantities indigenously in the localities mentioned, the supply of the material is inexhaustible.

—A correspondent at Stockport tells us: The latest medical bull perpetrated in this direction occurred last week, when a doctor was called in to see three sick children, for whom he prescribed. A few hours after, the mother came to him in great trouble, telling him that two of the children had died. "But," said Dr. —, "I gave you medicine for three. Where is the other?"

—The Surgeon-General of the Marine Hospital Service is informed that small-pox is epidemic in Louisville, and there were seven deaths from the disease in the Marine Hospital in that city during the last week of January.

—The Secretary of the Treasury has approved a recommendation of Surgeon-General Hamilton that an immediate inspection be made of the cities bordering on the Gulf of Mexico and the Caribbean Sea having commerce with the United States, in order that their actual sanitary condition may be known in advance of the yellow fever season. A medical officer of the Marine Hospital Service and a revenue marine officer will be detailed for the inspection.

ORIGINAL DEPARTMENT.

COMMUNICATIONS.

THE UNKNOWN FACTOR IN THE EQUATION OF THE NERVOUS SYSTEM.

BY J. M^r F. GASTON, M. D.,
Of Atlanta, Ga.

(Concluded from page 388.)

An independent order of small uniform tubes serves to connect the final ramifications of the arteries and the initial developments of the veins. Even in the original investigations of Harvey, upon the circulation of the blood, communicating channels were recognized, by which the transfer of the blood from the arteries to the veins becomes established. Yet, the discovery of a distinct arrangement of vessels, known as the capillary system, was reserved for the genius of Malpighi, who elucidated the general properties of this connecting-link in the circuit of the blood. The special physiological role of these intermediate tubercles is not, however, as yet, fully comprehended. It is evident that the blood is conveyed through this network of filiform ducts from one to the other set of vessels; but what physical law controls this transmission has not been clearly defined; nor is the element that effects the appropriation of alimentary particles, and causes the alteration in the blood, duly understood. The impulse given by the heart, propagated through the elasticity of the coats of the arteries, is sufficient to urge forward the column of blood in its course until it reaches the capillaries.

After passing through this sieve-like structure, and undergoing a process by which its nutrient

elements are incorporated into the various tissues, the current of the blood enters the small initial venous branches on the other side, and under the influence of the *vis a tergo*, and the suction of the gradually enlarging calibre of the veins, it is then conveyed along the venous trunks, until, by the active dilatation of the right ventricle, it enters the heart. This seems all very simple; but what is the nature of the dynamic action upon the blood in its passage through the intermediate conduit betwixt the arteries and the veins remains to be settled. It is the province of all tubes of small calibre to promote the entrance of fluids to a limited extent, even against the force of gravity. Beyond this capillary attraction, there is nothing in the anatomical arrangement of these tubes which determines the flow of blood. The capillaries have an action distinct from the heart; but what is the character of that capacity for independent action is not well understood; and this factor is lacking for a due comprehension of the correlation of the vital forces.

The vaso-motor system supplies the nerve element that pertains to the coats of the arteries, and it may appear that we need not look beyond this recognized distribution of the ganglionic nerves for a clue to the circulation of the blood; yet the student of physiology will fail to discover in the ramifications of this class of nerves any correspondence to what has been referred to as the dynamic property of the nerves.

While the excito-motor element of the nervous system is intermittent and even accidental in its manifestations, and the excito-secretory function is variable, being dependent upon many concomitant circumstances for its operation and results,

the vaso motor system does not sufficiently elucidate the supposed relations of the external and internal parts of the body, that are vaguely comprehended in the term sympathy.

The property of the nervous system which I would indicate as the excitodynamic element is more constant and continuous in its bearing upon the physical and vital operations of the organism. In its inherent quality of sustaining the forces of the organization, we have, as it were, the main-spring of life. Either of the other attributes of nerve-power might be arrested temporarily without impairing seriously the performance of the vital functions. Should there occur, however, any interruption of the function of the dynamic system, the machinery that is dependent upon its influence would cease to act, and death must ensue.

The due operation of this vital force, if I may use a much abused term, can be modified, but not suspended, consistently with the role of the various organs, nor can it be interrupted for any appreciable period consistently with the life of the organism.

It is evident that the plexus of nerve fibrils that enters into the network of the capillaries is so correlated with the ganglionic system of nerves as to afford a connection with the entire corporal structure, and that through this channel an influence is propagated to every part of the physical organization for good or for evil. The data here presented afford a proper basis for practical experiments as to the relations of the nerves to vital force; and I trust that the connection of the subcutaneous nerves and capillaries with the internal organs and the entire organism may soon be clearly defined.

The transmission of a telegram by the electric fluid does not more clearly prove the existence of the battery and the conducting wire, by which it passes, than the facts growing out of the developments of health and disease demonstrate a nervous connection which implies the excitodynamic function of the central system of nerves.

This inference from clinical observation requires confirmation by a series of experiments; and I await with confidence the results of experimental investigation respecting the intricate and complicated relations of the cerebro-spinal and ganglionic nerves for the presentation of facts to sustain my theory of an excitodynamic division of the nervous system, independent of the vaso-motor nerves.

Whatever doubts may be entertained as to the route traced by poisons that are brought into

contact with the minute net-work of the nerve fibrils and the capillary vessels in the areolar and cellular tissues, there can be no question as to an extraordinary and rapid transmission of an injurious impression to the other tissues, and to the different internal organs. The point to be set clear in a clinical aspect, is the reciprocal relation of cause and effect; and the clue to a rational solution must rest with experimental physiology.

The constant operation of impressions by a link of connection independent of the afferent and efferent nerves, strengthens the inference from clinical observation, in favor of a special nervous communication between the outer and inner parts of the body. If this hypothesis can be sustained by future experimental demonstration, it may be accepted as a final and satisfactory explanation of the unknown quantity in the problem of physiology and pathology, as respects the nerve element.

The same difficulties that are encountered as to the true explanation of the prompt effect of poisons, which are introduced beneath the cuticle, present themselves in the consideration of the influence of subcutaneous remedies. Should my suggestion prove to have a proper basis, it may seem to relieve all cases in either department of any embarrassment.

In deducing from facts the great principles involved in the reciprocal relations of the different parts of the organization, we have a rational explanation of the physiological and pathological development of the organism in the vital functions. If my effort to illustrate the principle I would inculcate fails to convey a distinct conception of what is to be supplied, it may at least suffice to create a strong presumption in favor of the reality of the basis upon which hypodermic and other medicated injections are preferred for the cure of diseases.

Some of these medicinal agents are introduced with a view to their remote influence, while others are used to modify the tissues into which they are injected, and hence for a purely local effect.

The aim of this paper is to impress the advantages of subcutaneous and other injections of medicinal agents over the administration of remedies by the mouth, and to inculcate especially that this depends upon the prompt introduction of the agent by the correlation of the nerve fibrils and capillaries with the central nervous system, and that the effect ensues to a large extent from a peculiar influence propagated to the organization of the various parts.

This final result of all such applications is not

a consequence of reflex action emanating from the excito-motor nerves, nor from the excito-secretory nerves, nor yet from the vaso-motor element of the nervous system. It is accomplished through a function of the nerves quite distinct from either of these recognized properties, and which underlies all other exhibitions of nerve power.

Conflicting opinions are held by those entitled to our consideration form their practical and experimental investigations, in regard to the relations of the nervous system to the dependent organs. While Brown-Sequard recognizes the medulla and spinal cord as the chief source of "the nerve influences in the tissues," Dr. W. H. Gaskell, by his investigations in the physiological laboratory at Cambridge, concludes that "many phenomena now believed to be produced by the agency of the nervous system may be really independent of it."

Until these antagonistic views of physiologists are reconciled by more conclusive experiments and observations, we must be content to grope our way, with the light of clinical experience.

As the theory proposed by Dr. H. F. Campbell in regard to the excito-secretory division of the nervous system, deduced from his clinical observations, was confirmed by the experiments of Marshall Hall, I await some similar result of experimental inquiry in support of my view of an excito-dynamic division of nerves, distinct from, and entirely independent of, the vaso-motor element of the nervous system. The local influence that effects an alteration in any part, is of little consequence, in comparison with the vital change which is operated in the tissues and organisms, by the relation of the excito-dynamic element of the central nervous system to the great sympathetic nerve and its ganglionic ramifications. The interlocking and interlacing that exists betwixt the distribution of the cerebro-spinal system and the ramifications of the organic system of nerves, afford the conditions upon which the sympathies of the excito-dynamic function of the nerves operate. This nice arrangement of the ultimate development of the minute fibres of the two sets of nerves, is found in the remote plexus associated with the distal circulation, destined to supply nourishment to every separate atom of matter that enters into the composition of the body. The interchange of powers growing out of this relation in all parts of the organization, being closely associated with the capacities of the deep-seated nerve-centres, presents a series of reciprocal actions, and the actions that constitute what are vaguely styled the sympathies of the different portions of the system, and which is

herein designated as the excito-dynamic element of the nervous system.

"RIGIDITY OF THE CERVIX UTERI AND THE USE OF ERGOT."

RY T. J. HAPPEL, M. D.,
Of Trenton, Tenn.

On page 232 of the MEDICAL AND SURGICAL REPORTER, February 28, 1884, I find an article on the above subject, apparently in the form of an inquiry as to the methods of procedure.

Labor, at best, is, to the patient undergoing its throes, a physiological process involving much suffering. It behooves medical men, therefore, to do everything that can safely be done to alleviate their pain, and to enable them to undergo with fortitude as well as safety their, to them, dreaded ordeal.

"Patience and a cheerful demeanor" on the part of the medical attendant are of prime importance in every case of labor, and especially in those characterized by rigidity of the os. One great reason why in former times lacerations of the cervix were not recognized, was that these lacerations much more rarely existed. Labor was not hurried through by the attending physician, that he might either rush to another case of labor, or that he might not lose his much-coveted sleep, or fail to make some other desired call, as is too frequently the case in these days of rush, and greed for gain.

Ergot and the forceps, two of the most powerful agents for good in obstetric practice, have inflicted upon females an unknown and an untold amount of damage. A labor lingers; a physician calls, a few questions are asked, a hurried examination is made; a dose of ergot, greater or less, as thought needed, is administered; tonic contractions of the uterus result: by the efforts of the woman the uterus and its contents are forced low down in the pelvis, the vertex is recognized as presenting, the forceps are applied, and the child forcibly delivered. The physician flatters himself that he has performed a skillful (?) operation, and goes off, after having made a slight examination of the perineum. The woman!—well, after a slow and tedious convalescence, she gets out; but, as she expresses it, "has no back." Later on, perhaps never, a lacerated cervix is recognized. I do not think I overdraw the picture. Ergot and the forceps are both abused.

To explain my own procedure, I would cite the following cases, occurring in my practice since January 1, 1884:

Case 1. January 7, 1884, was hurriedly called to visit —, colored. The messenger reported that, after some slight pains, the waters had broken; since then, that the intervals between the pains had been long and irregular. I reached the case at 3 p. m. The facts, as stated above, were repeated. The patient was a large, fleshy female of relaxed, scrofulous habit; multipara, third labor. An examination revealed the uterus high up, the os dilated about an inch, but very dilatable, thick, flabby. The pains were slight—intervals from fifteen to thirty minutes. After delaying and watching a few pains, I administered liq. ergotæ purificat., ℥ xv.; fl. ext. ipecac, ℥ ij. to ℥ v. M., every fifteen minutes, till four portions had been given. When the pains began to increase in frequency and strength, I then gave a double portion of the R. at a dose, and at 4½ p. m. the patient was safely delivered. No trouble from the placenta, which was removed in about five minutes. No hemorrhage. Before leaving I gave liq. ergot. pur. ʒj. Patient did well. Suffered but little from after-pains.

Case 2. January 17, 2 a. m., Mr. — called me to see his wife. Third labor. Waters had broken after a few pains, which had recurred irregularly from twelve o'clock. Patient was nervous, dreading the labor, on account of the, to her, irregular beginning. Soon quieted her fears, and made an examination. Os rigid, not dilated enough to admit the extremity of the index finger. Administered at once R. morphiæ sul., grs. ¼; atropiæ sul. grs. ⅛, hypodermically. In half an hour the patient was free from all pain and nervousness, and soon went to sleep. Left her and returned home, a short distance off.

Called at 9 a. m. Patient had rested well; was feeling slight pains occasionally. An examination revealed an os dilated to the size of half-a-dollar, and dilatable slightly. Repeated the hypodermic injection same as before, and left, with directions to call me when pains returned.

Was summoned at 4 p. m. Found pains regular; patient cheerful, had slept and rested well until an hour before; had not vomited. Dilatation almost complete; uterus low down; all the parts soft and dilatable. By 5 p. m., the patient was delivered of a seven-pound girl. During the expulsive pains chloroform was used. After the expulsion of the child, liq. ergotæ pur. ʒj. was given. The placenta was delivered in less than ten minutes.

Case No. 3. January 18, 3 a. m., Mr. — called me to see his wife, multipara, seventh child. He reported that at 1 a. m. his wife was aroused by the escape of "the waters." Arriving

at the house, about three miles out of town, I found the wife sitting up, cheerful, but a little nervous, over what she expected to be a tedious labor. An examination revealed a thick, rigid os. Treated as Case No. 2, and at 2 p. m. pains began to be regular. I found upon examination an os dilated about two inches, somewhat dilatable, thick. Gave

R.	Liq. ergotæ pur.,	℥ xv.
	Fl. ext. ipecac,	℥ v.
M.		

And repeated dose in 15 minutes.

In half an hour after the second dose labor ended. Chloroform was offered during the second stage of labor, but was refused. The case was completed as in the second case.

Case No. 4. January 22. Was called at 2 a. m. to see Mrs. —, multipara. The history of No. 3 was repeated. Was soon at the bedside. Pains were vigorous, os dilating steadily; no rigidity. Nothing was given until the expulsive pains began, when a small amount of chloroform was inhaled. Labor was completed at 5 a. m. Ergot was administered after the expulsion of the child, as in the other cases. The placenta was extracted in five minutes, without trouble.

Case No. 5. January 24. Visited her. Multipara, third labor. Nervous and hysterical. Claimed to have suffered for forty-eight hours. No dilatation of the os, parts rigid, and rather dry. Hypodermic injection of morph. sulph. gr. ⅓, combined with atropiæ sul. gr. ⅛, was administered. In twenty minutes she became quiet and sleepy. Returned home. Was called the next night at 9 p. m. Had vomited from the morphia. Pains regular. Os rigid, but slightly dilated, membranes protruding. A small fibroid, about the size of a small hickory-nut, on the anterior external surface of the anterior lip of the cervix. Repeated the hypodermic injection, and waited. At 12 m., the os began to relax and dilate, the posterior half of the cervix being very dilatable, the anterior being markedly interfered with by the fibroid. Pains were very inefficient, and after a little delay, began using the ergot and ipecac, as in Case 3, in the same dose, repeating every fifteen minutes. The pains soon increased in efficiency. Patient vomited frequently. Soon after the fifth dose dilatation was completed. The head passed the os without laceration, and labor was completed under chloroform at 2 a. m. The membranes did not rupture till just before the birth of the child. Before leaving, gave ergot, as in the other cases.

Case No. 6. January 27. W. B., multipara.

Labor began with the escape of the waters at midnight. Saw her at 8 a. m. Pains had been light, irregular, and inefficient. Os soft, thick, dilated an inch in diameter, very dilatable, soft parts much relaxed. Waited an hour. Only one or two very slight pains. Gave

R. Liq. ergotæ purif., $\mathfrak{m}\text{xx.}$
Fl. ext. ipecac, $\mathfrak{m}\text{iv.}$

M.

Repeated every 20 minutes.

After the third dose active labor began. At 10 a. m. dilatation was complete. Child was expelled at 11 a. m. Ergotæ $\mathfrak{z}\text{j}$ was given at once. In ten minutes the placenta came away, under friction over the uterus, and slight traction upon the cord.

Case No. 7. February 18. Visited Mrs. —, primipara, at 4 a. m. Labor began with the rupture of the membranes and escape of the waters at 1 a. m. Patient was nervous and despondent. Digital examination revealed uterus high up, os rigid, no dilatation. At once gave hypodermically R. Morphine sul., grs. $\frac{1}{4}$; atropiæ sul., grs. $\frac{1}{80}$. Quiet in twenty minutes. Left her. At 10 a. m. pains returned. Os rigid, but dilating slowly. Repeated the hypodermic injection. At 1 p. m. pains regular; os dilating—thin, soft; patient cheerful. At 3 p. m. the pains, though regular, were short, and devoid of strength. Began giving liq. ergotæ, $\mathfrak{m}\text{xv.}$, repeated every twenty minutes. After the third dose pains more active, and at $4\frac{1}{2}$ p. m. patient gave birth to an eight-pound boy. No laceration, and but little soreness. Urine was drawn with catheter once, after labor. Chloroform was used during most of the second stage, but weakened the pains. Case was completed as the others.

Case No. 8. February 21. Attended Mrs. — in her second confinement. Waters discharged with first pain at 3 a. m. Was called at 8 a. m. Patient in best of spirits; pains slight and at long intervals; os soft, thin and dilatable; external parts well relaxed. After waiting an hour, I gave ergot $\mathfrak{m}\text{xx.}$, and in twenty minutes repeated it. At 10 a. m., pains more active and regular. Then give

R. Liq. ergotæ pur., $\mathfrak{m}\text{xx.}$
Fl. ex. ipecac, $\mathfrak{m}\text{vj.}$

M.

At 11 a. m. expulsive pains began, the dilatation being complete. Before 12 m. a $7\frac{1}{2}$ -pound girl was born. Chloroform was used as in case No. 7. The placenta was removed in five minutes, the extraction being preceded by the ergot, $\mathfrak{z}\text{ss.}$

In my whole practice I have never met with as many consecutive cases, beginning as these did with the discharge of the waters.

The histories given set forth the treatment that I follow in such cases.

In all cases of rigidity of the os, with little or no dilatation, I use the hypodermic injection of morphia and atropia, proportioning to suit each case. I regard the combination as better than morphia alone. Pain is relieved by the morphia, and at the same time none, or at worst but *few*, of its unpleasant effects are experienced. Atropia counteracts many of them, stimulates the patient, keeps up the the capillary circulation, etc.

In the course of four hours, if needed, I repeat the injection; but if the os is dilating and thin and dilatable, I do not.

My experience with chloral in such conditions has not impressed me favorably. Chloral has proven with me, in safe doses, only an hypnotic, not an anæsthetic. In full and repeated doses it might have, and no doubt does have, anæsthetic properties strongly marked. I think I am sustained in these views by Ringer in his Therapeutics.

Gelsemium is unreliable.

In most primiparous cases, except such as are unusually rapid, I give morphia and atropia to prevent the wearing out of the patient during the tedious first stage of labor.

In cases where the os is partially dilated, dilatable, thin, and the pains normal and effective, I do nothing, but trust solely to nature; but in the same condition of the os, with the pains slow, irregular, and ineffective, I administer liq. ergotæ purif., or fl. ext. ergotæ $\mathfrak{m}\text{xv.}$ — $\mathfrak{m}\text{xx.}$, repeated every fifteen or twenty minutes, adding usually after the third or fourth dose, fl. ext. ipecac $\mathfrak{m}\text{v.}$ — $\mathfrak{m}\text{x.}$

In cases where the os is partially dilated, soft, dilatable, but thick, if the pains are normal, I administer a few doses at intervals of fifteen minutes of fl. ext. ipecac $\mathfrak{m}\text{v.}$ — $\mathfrak{m}\text{x.}$; but in the same state of the os, with pains slow, irregular, and accomplishing nothing, I administer liq. ergotæ pur. $\mathfrak{m}\text{xv.}$ — $\mathfrak{m}\text{xx.}$, fl. ext. ipecac $\mathfrak{m}\text{iv.}$ — $\mathfrak{m}\text{vj.}$. Repeat every fifteen or twenty minutes through the first stage of labor.

In cases where the os is thin, partially dilated, but not dilatable, with pains active, I use chloroform.

In cases similar to the last, except a thick os, I would administer hypodermically morphia and atropia, and then if necessary follow with ergot, or ergot and ipecac.

Where the membranes have not ruptured, and where no rigidity is present, I trust to nature, except in cases of primiparæ already referred to.

In a practice of more than ten years, taking the above rules as my guide, in my own practice, in about six hundred cases of child-birth, I have never had to apply the forceps, nor had a lacerated cervix or perineum, but have frequently in consultations used the forceps—in two cases recently—and have seen and operated on two cases of lacerations of the perineum, and one of the cervix; and have recently been consulted about two other lacerations of the perineum within less than three months.

One further use for ergot in obstetric cases. As soon after the expulsion of the child's head as possible, and always before removing the placenta, I give ʒj. of ergot, and unless very firm contraction of the uterus takes place, before I leave the house I repeat the dose.

I have never been troubled with excessive hemorrhage.

A CASE OF SCIRRHUS OF THE PANCREAS SIMULATING ABDOMINAL ANEURISM.

BY M. W. LILLY, M. D.,
Of Grand View, Iowa.

Mrs. J. D. Wade, aged fifty-three, rather above the medium size, and of a bilious temperament. Has been poorly for years; mostly bilious and neuralgia, with a special tendency to stomach and uterine troubles.

History.—In the evening of September 1, 1883, I was called to see her. She was sitting up, and gave me about this history: More or less of the time since February last, has been troubled with a burning pain a little to the left of the pit of the stomach. Sometimes it is a throbbing, and then again a shooting pain, upward into the heart and gullet, into the back, and occasionally downward. Sometimes the burning seemed more in the œsophagus than in the stomach, but not often. Food, even in small quantities, distressed the stomach, and made the pain worse immediately after being taken, but otherwise the functions of the stomach were not much impaired. But seldom troubled with flatus or costiveness. Kidneys and bladder gave her some trouble, also a cough; but these, she said, were not worse than they had been for the last fifteen years at times. Another physician had had the care of her for the last six or eight weeks. I found her decidedly salivated from medicine taken that morning, some of which remained, together with some large doses of salicylate of soda and some drops containing belladonna and gelseminum. I discontinued these, and applied myself to the pyalism and the purging and vomiting which still continued.

On the 2d doing fairly well.

On the 3d I examined the stomach more carefully—had been too irritable before—and found it not very tender except on deep pressure. At this visit I first discovered a small pulsating tumor, which I judged to be behind the lower edge of the stomach and transverse colon, and an inch to the left of the median line. In size it was about as large as one's finger, by 2 or 2½ inches long, lying vertically, and rather tender. On the palmar surface of each hand, opposite the carpo-metacarpal joint of the fourth finger, was a small purplish spot, about 5 by 8 lines in extent. They were under the skin, and disappeared under pressure. The pain in or under the stomach being worse of evenings, I gave quinine and applied a blister.

I saw her on alternate days till the 10th, during which time I blistered twice, and gave sulph. hydrastis, willow charcoal, and chlor. potash, on which she improved. Spots on the hands spread a little.

Did not visit her again until the 20th, and again on the 27th. Found but little change.

October 2. A good deal of pain in the uterus, particularly if on her feet at all. Made an examination per speculum, finding a small abrasion only on the posterior lip, though considerable cervical endometritis and leucorrhœa.

October 10. About the same.

October 18. Saw her with Dr. J. H. Graham, of Morning Sun. Found her about the same as on my last two visits. We used local treatment for the uterus, and continued small and frequent blisters over the stomach, with the wil. charcoal and chlor. potas. internally.

November 19. Saw her again, with Dr. Graham, to-day. For the last month I had found her gradually growing worse. The tumor was perceptibly larger; also, the spots on the hands, which now cover nearly all of the palms but the centres, and the face and edges of most of the fingers from the nail to the first joint. They are mostly of a deep scarlet color, in which are smaller purplish spots, somewhat raised, exceedingly tender, and having a constant burning pain which nothing relieves. Some days both these colors are more marked, and the spots more tender, at which times the pain and distress about the stomach are usually better. Also, at this period she had three or four slight attacks of conjunctivitis. The burning, throbbing pain in the stomach and tumor is becoming more constantly severe, and the strength and flesh failing. Food distresses the stomach very much, it being with the utmost care that she can

take any nourishment. Can sit up but little now, and lies with limbs flexed to relieve the tension of the abdominal muscles.

As to treatment during this time and for the three following weeks, we tried many things, among which were nitrate of silver, dil. phosph., and sulph. acids, aqua calcis, creasote, bromid. potass., deod. tr. opium, and fl. ex. Jamaica dogwood. The last two the stomach would not retain, and the others did no good, or but for a short time only. Blisters were frequently repeated, but they have lost their efficacy, and vesicate but poorly. The charcoal and chlor. potass. would usually give the most relief of anything used. We urged the hypodermic injection of morphia, but she would not consent to it till December 7th, when she became much worse, and the pain unbearable.

(*To be Continued.*)

ATONY OF THE BLADDER.

BY J. B. JOHNSON, M. D.,

Of Washington, D. C.

I was called on the 15th of November to visit Mr. S., at Harper's Ferry, West Virginia. I found him to be a man of seventy-two years, with a good constitution, temperate habits, and moral character. His appetite was good, tongue clean, and bowels regular. He said he suffered no pain, but felt himself growing gradually weaker, and that he had lost all power to pass his water; that day and night it was dribbling from him, unfitting him for business, causing great inconvenience, keeping him constantly wet, and always with a cold; and that he had been in this condition for two years, but for the last six months his difficulty had steadily increased. On exposing the abdomen, I saw the urine coming away, drop by drop; and placing my hand over the bladder, found it hard and distended, occupying the whole hypogastric region. He had never been catheterized, and possessed great dread of the instrument; but on being assured that its use was of the utmost importance to an intelligent understanding of his case, he readily gave his consent to its use; and selecting a well-curved No. 11 gum catheter, I passed it, well oiled and warmed, without the slightest obstruction, into the bladder, and as soon as the point of the catheter entered the bladder, the pent-up urine began to flow freely through it, and continued to flow until *four pints and a half* passed off. I then stopped the flow of the urine by withdrawing the catheter, and administered immediately by the mouth sixty drops of tincture of opium to keep off nervous excitement, and

requested him to go to bed and be quiet. He suffered not the slightest faintness during the emptying of his bladder: and four hours after the first use of the catheter, I requested him to introduce for himself the instrument into the bladder, which he did without pain or trouble, and again one pint and a half of urine passed off. I then repeated the sixty-drop dose of tincture of opium, and left him in charge of Dr. Spangler, of Harper's Ferry.

This was a well-marked case of atony of the bladder, unattended by previous disease of either the brain or spinal cord, and attended by very slight enlargement of the prostate gland. It was a loss of the contractile power of the muscular coat of the bladder, and caused by a slight enlargement of the prostate gland, attended with the habit, on the part of the patient, of retaining his urine too long in the bladder. It painlessly came on gradually, and its increasing presence was more and more manifested by an increase of the escape of urine drop by drop, accompanied by frequent and unsuccessful efforts to urinate. The catheter, rest, tonic medicines, and nourishing diet, are the only means we possess of palliating such distressing troubles of advanced life.

MODIFICATION OF COHEN'S LARYNGEAL FORCEPS, MAKING THEM ADAPTABLE FOR POST-NASAL, PHARYNGEAL, AND LARYNGEAL APPLICATIONS.

BY CHARLES E. SAJOUS, M. D.,

Instructor on Laryngology and Rhinology in the Summer and Post-Graduate Courses, Jefferson Medical College, etc.

The spring, slide and catch, and general conformation of Dr. Cohen's valuable instrument having been preserved, the only modification, as shown in the cuts below, is in the shape of the curve, which, instead of a right-angle, assumes that of the arc of a circle, with retrocession of the tip towards the centre.

In the posterior nares, this peculiar curve renders it available for applications to the turbinate mucous membrane, mouth of the eustachian tubes, pharyngeal vault, etc., the position of the tip being regulated by that of the handle. In simple curves, that is to say those in which the axis of the tip is at right-angles with that of the handle, the tip does not reach the inferior turbinated bones, or the floor of the posterior nares, the depression of the lower jaw not permitting sufficient depression of the handle.

For the pharynx, it takes the place of the straight forceps when held horizontally, directing the tip toward the pharyngeal wall, and enables the operator to medicate in one application the whole tract from the vault to the beginning of the œsophagus.

For the larynx, the curve following a line passing over the tongue and the posterior surface of the epiglottis to the middle of the vocal bands, it preserves the advantages of right-angle instruments, without involving their difficult manipulation.

The instrument is smaller and lighter than Dr. Cohen's.

—Iodoform is being adulterated with picric acid, according to Jules Libert, a pharmacist of Liège, Belgium.

HOSPITAL REPORTS.

A CLINICAL LECTURE DELIVERED IN THE HOTEL DIEU, PARIS, FRANCE.

BY DR. F. RAYMOND.

Fellow of the Society of Medicine, Physician to the Hospice des Incurables.

1. Acute Meningitis in the Course of Typhoid Fever. 2. Tubercular Meningitis in an Adult.

(Continued from page 394.)

This case is worthy of a place among several others which have been published. The meningeal complications, and those pertaining to the nervous system generally, in the course of general diseases, of grave pneumonias (the pneumonias, for example, which occur in alcoholic patients), in erysipelas, etc., are to-day well-known. You ought, in this connection, to consult the excellent thesis of M. Landouzy, in that part which concerns principally paralysis complicating acute diseases. Many pathogenetic theories have been put forth to explain such complications. Without stopping to discuss these pathogenetic theories, I desire to remark that typhoid fever is in reality a disease *totius substantiæ*; it affects all the anatomical elements, and hence the encephalon as well as the other organs. What is there then that is strange in the fact of a cerebral complication arising in a person predisposed? Has it not been remarked that the secondary meningitis of pneumonia is seen principally in drunkards predisposed by their habits to cerebral affections? Is it probable that our patient was rendered liable to this cerebral malady by his occupation? I simply put the question. It is by no means improbable that some would be disposed to blame the salicylate of magnesia for the cerebral manifestations from which the patient died. Salicylate of soda has been accused of producing meningitis when given in large doses for acute articular rheumatism, especially in the case of alcoholic patients; those particularly who were suffering from renal lesions. When given for typhoid fever the same remedy has been accused of determining cerebral complications.

In support of this view, we have been reminded of the nausea and vomiting which sometimes attend the administration of this agent. It has also been said that in some cases the cephalalgia has been greatly aggravated. I have no personal experience in this matter, as far as typhoid fever is concerned, nor have I ever seen accidents of this kind in rheumatic patients treated with the salicylate. It is true that I took care beforehand to assure myself that my patients were not alcoholic, and that there was no kidney trouble. In the case under consideration, ought we to incriminate the large doses of salicylate of magnesia employed? I do not think so, because the patient at no period of the administration of the medicament had either nausea, or vomiting, or excess of pyrexia; in a word, there was no symptom of poisoning. All these points, however, deserve to be brought up and discussed.

2. I shall be more brief in my account of the second case. You see before you, gentlemen, portions of the diseased organs of the patient, the results of the autopsy. I shall attend only to

the essential particulars of the clinical history, facts of this kind being relatively numerous. The patient concerning whom I am to speak is a female aged 45, who entered the hospital August 16, ward St. Jeanne, No. 21.

August 17, when I made my morning visit, I found her in a state of stupor, almost insensible to everything happening around her; she was with difficulty made to reply in monosyllables to questions asked her. She complained of violent headache, the pain being all over the head, also of utter prostration. The head was inclined towards the right shoulder, the face looking upward and to the left; and on trying to straighten it, we met with great resistance, due to contraction of the muscles of the back of the neck. The patient could not bend the head, and if force were used to bend it, she uttered outcries and complained of violent pains in the occiput and back of the neck. There was a slight degree of contraction in the right arm; the left arm and the left lower extremity were unaffected. General hyperæsthesia. Pinching or compression of the arms or legs, elicited severe pain. The right upper eyelid was closed, as if by paralysis of its elevator muscle. There was contraction of both pupils. The skin was hot and dry, temperature 101.5°F. , pulse small and irregular, every ten or twelve pulsations being followed by precipitation of the beats, which then became slower. Heart's action feeble; marked arrhythmia. Radial arteries atheromatous. The tongue was covered with a dirty white fur, appetite nil. No vomiting at the time of examination. Retraction of the abdomen (*en bateau*); obstinate constipation. Respiration was painful, irregular, 40 a minute, sometimes slow and sometimes quick. Dullness in the suprapinnous fossæ, especially on the right side. The same dullness under the right clavicle, with prolonged expiration of a blowing character. Expectoration scanty and purulent. Urine high colored, scanty, albuminous. The patient had subsisted by shelling peas at the central market; her diet had been poor and inadequate; she had been addicted to alcoholic excesses. For four years past had suffered during the winter from colds and coughs all the time; never had hæmoptysis. Nothing worthy of note on the part of ancestry. Eight days ago, on returning from her work, she had a slight chill; this was repeated in five or six hours, with general malaise, prostration, vertigo. Appetite failed; nausea, vomiting and constipation supervened. She was restless nights and had nightmare. Profuse perspiration.

The diagnosis of this case presented some difficulty by reason of the age of the patient and the suddenness of the attack. Was this woman tuberculous? On taking into consideration the signs furnished by auscultation, by percussion, by the expectoration, the emaciation, the fever, the antecedent attacks of bronchitis, it seemed like a chronic case of phthisis, which had not yet made much advance, for the stethoscopic signs were not well marked. In the second place, one might ask if we had not before us a case of typhoid fever or of simple *embarras gastrique* in a tuberculous patient? The state of profound prostration, the contractures, the partial paralysis, pleaded against this supposition, which was abandoned. The woman was a victim of intemperance.

Was there here chronic meningitis with recent acute exacerbation, and, perhaps, pachymeningitis? Many of you thought so, but there was nothing in the history of the case to make this diagnosis very probable. The other hypotheses suggested, acute simple meningitis, cerebro-spinal meningitis, cerebral tumors, tubercles of the cerebrum, did not sufficiently explain the assemblage of symptoms, and were abandoned.

How then were we to interpret the cerebral symptoms in this case?

The diagnosis of tuberculous meningitis, secondary to incipient phthisis, seemed sufficiently to explain all the phenomena observed. On taking into consideration the headache, the initial vomiting, the heat of the head, the contractures, the fever, I judged it to belong to the *inflammatory* form of tuberculous meningitis, which is contrasted with the *torpid* form when the symptoms are slower in their evolution. The march of the affection justified this view. The day of admission I ordered ice to the head, and prescribed a calmative draught containing codeia.

August 18. Somnolence more profound. Morning temperature 102.5°F. , evening temperature 102°F.

August 19. Sleep very much agitated during the night. This morning, profound stupor, speech embarrassed and difficult. Morning temperature 101.3°F. , evening temperature 101.4°F.

August 20. Through the night the patient was delirious, requiring the strait-jacket. The contracture of the muscles of the back and neck has increased. The patient is quite demented. Complete drooping of the right upper eyelid. Morning temperature 100.8°F. , evening temperature 101°F.

August 21. Same general condition. Some strabismus affecting the external rectus of the right eye. Right pupil very much dilated. Morning temperature 100.5°F. , evening temperature 100.8°F.

August 22. Respiration difficult, irregular, 46 per minute; pulse small, feeble, irregular, 102 per minute. The patient is plunged into a sort of cataleptic state. If you raise the left arm, it remains elevated ten or more seconds. You can put it in any position, and it continues there for some time.

Death took place on the 23d at 9 a. m. Autopsy made the 25th, in the morning.

Thoracic Cavity.—Dry pleurisy at the summit of the chest. The adhesions were much more pronounced at the right than at the left apex. A number of tubercle granulations in the former situation. There were also a small number of calcified granules in the pulmonary tissue, otherwise healthy. Heart normal, aorta somewhat atheromatous.

Abdominal Cavity.—The liver has the normal appearance. The kidneys are congested; their capsule peels off easily; a few tubercle granulations in the renal parenchyma, near the surface. The spleen and the organs of generation present nothing worthy of note. The mucous membrane of the stomach is mamillated and congested, and presented several ulcers, each the size of a small pea.

Nervous System Encephalon.—In the meshes of the pia mater exists a glutinous exudation, sur-

rounding the circle of Willis and optic chiasm. This exudation, embedding the basal nerves of the right side, extends along the fissure of Sylvius. In the midst of this exudation, fine tubercle granulations are visible to the naked eye. These are especially abundant along the sylvian artery, and in its parietal branches. In separating the convolutions which bound the fissure of Sylvius, a crop of fine tubercle granules is seen in the web of pia mater, covering the island of Reil. This is intimately attached to the underlying tissue of the brain, and is removed with difficulty. No spots of hemorrhage or softening apparent to the naked eye. The tuberculous exudation of the left hemisphere is especially abundant in the region of the ascending frontal convolution near its middle portion. The pons, rachidian bulb, the cerebellum, have their normal appearance. Along the spinal cord, principally on its posterior aspect in the dorsal and lumbar regions, tuberculous exudations of the pia mater are sufficiently abundant, and very adherent to the surface of the cord.

This observation seems to me interesting in more than one respect: 1. As M. Lionville has well pointed out, tuberculous meningitis, in clinical practice, is generally both spinal and cerebral. 2. The distribution of lesions at the base of the brain, their predominance on the left side, well explains the symptoms observed during life; the paralysis of the right levator palpebræ, the contraction of the right arm. 3. It is quite remarkable, despite the contracture of the muscles of the back of the neck, to see that the meningitis had not invaded the cervical region of the cord. 4. The age of the patient is a fact quite exceptional, and which ought to be noted. 5. The slight extent of the pulmonary lesions, which moreover were old, in contrast with the acute recent extensive tuberculous invasion of the encephalon, the spinal cord, and the kidneys, the other organs being healthy, constitutes also an important clinical peculiarity. 6. The etiological antecedents of the disease, our patient having been insufficiently nourished, and addicted to alcoholic excesses, ought also to be noted.

A CLINICAL LECTURE DELIVERED AT THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

BY WILLIAM PEPPER, M. D., LL. D.,

Provost of and Professor of Clinical Medicine in the
University of Pennsylvania.

Reported by WILLIAM H. MORRISON, M. D.

Obstruction of the Small Intestine—Exophthalmic Goitre.

GENTLEMEN: I shall first ask your attention to this young man, who gives the following history: J. W., age twenty-one, an iron founder. It is stated that, even from infancy, the bowels were obstinately constipated. At the age of two months the bowels were never opened unless a laxative were given, and it required double doses of the ordinary remedies to secure a passage. This continued until he was seventeen months old, when he had an attack of looseness of the bowels, accompanied with the discharge of mucus and blood. At the age of two years, the bowels became more

than usually constipated, and this was followed by stercoraceous vomiting. Vomiting of this character continued for seven months, the spells of vomiting recurring on an average about once a month. All this time, the belly was swollen, and he complained of intense colicky pain. After this, the bowels became less constipated; laxatives would act, and the vomiting disappeared. The belly, however, remained large. Gradually the pain disappeared, and for years the bowels were moved once every day, with hard, constipated stools. The belly has occasionally gone down to its natural size, but it never remains small for longer than three months at a time. Notwithstanding this condition, he grew, kept his strength, and was able to go to work in an iron foundry. His appetite is pretty good, and he has always been careful in what he eats, and chews his food well. He has a great deal of wind, which passes freely. The great distension of the abdomen has caused some shortness of breath.

Let us now turn to the physical examination of the patient. The heart pulsates above the line of the nipple in the third interspace, the apex beat being fully two inches higher than usual. There is no murmur over the heart, and there is no cough. The pulmonary resonance is normal all over the chest. The amount of dullness that can be developed over the liver is very slight, the resonance from the distended intestines almost meeting that of the lung. A glance shows you the remarkable figure of this patient. He looks like a man with enormous ascites from cirrhosis of the liver. There is uniform and extreme distension of the abdomen. From the history which has been given, it is evident that this enlargement is not due to the presence of liquid, but to the accumulation of gas in the intestine. He passes large quantities of wind from the bowel, and what is passed is very offensive. The surface of the abdomen is not smooth as it is in ascites, but there are varying curves and depressions, mapping out especially distended portions of the stomach and intestinal canal. The abdominal veins are slightly distended, forming in places little stellar groups, but there is not the great distension of the abdominal venous channels which is seen in cases where the obstruction to the abdominal circulation is as great as comes from cirrhosis or other mechanical obstruction. In the epigastric region the abdomen is remarkably prominent. In the hypogastrium, the distension is much less. On percussion, there is resonance everywhere, but the resonance varies in degree. Over the lower portion of the abdomen, the resonance is high pitched, and has a hardness about as though the intestine, while greatly distended, also contained some fluid or solid material. Over the prominence which occupies the upper zone, the resonance is loud and of great volume. The bowels have been opened once or twice for the past few days, this action having been produced by the medicine which he is now taking. The stools consist of one piece of hardened feces, about two inches long, and of the thickness of the thumb. He has passed feces in the shape of balls, but he has never noticed any ribbon-like feces.

If there were any narrowing at a portion of the bowel which would interfere with the passage of hardened feces, we should probably find some

evidence of it in the shape of the evacuation. This is to a certain extent a reliable sign of the existence of mechanical obstruction low down in the intestinal canal; and by the term "low down" I would imply a narrowing in the colon or lower part of the ilium, because by the time the feces have reached the point mentioned, their consistence is such that if they were forced through a constricted portion of intestine they would probably retain the shape given to them. Mechanical obstruction high up in the small intestine will not reveal itself in the shape of the feces, because at this point they are liquid or semi-liquid in consistence, and there may be a very close obstruction, requiring that the contents of the bowel be extremely liquid before they can pass, and yet the stools give no sign of its existence.

It must be admitted that in this case the stools afford no evidence of the existence of mechanical obstruction; and if such obstruction is present, we may exclude the idea of its being low down in the intestinal tract, and infer that it must be high up in the ilium or jejunum.

The common lesions of the intestinal mucous membrane, such as ulceration and the like, which give rise to the narrowing of the bowels and consequent mechanical obstruction, are far more common in the colon and the lower portion of the ilium than in the higher bowel. The lesions of dysentery, and those of severe ulcerative enterocolitis, the common form of grave summer complaint in children, are of course more marked in the colon and ilium than in the jejunum, and therefore if the contraction follow the cicatrization of an ulcer, it is most likely to be in the lower part of the bowel.

We cannot very well determine from the shape of the abdomen, the situation of a mechanical obstruction, supposing one to exist. The extreme distension obliterates the usual landmarks, and the dilated bowel thrusts itself over the viscera, preventing us from recognizing which portion of the intestinal canal presents. At first glance we might think, from the immense size of the epigastrium, that the stomach was in a state of gigantic enlargement and dilatation; but this appearance is very deceptive, and as I am speaking, you have an illustration of what I am saying. You see as the wave of peristaltic motion passes over the abdomen, that this prominence is divided by a deep sulcus, which is quite a different appearance from what we should expect if this were one large cavity. This is probably an immensely distended coil of intestine, but it is impossible for me to say whether or not any portion of this prominence is made up by the stomach. The only way in which this could be determined would be by a careful catheterization of the stomach—see how far an olive-shaped bougie will pass, and then measure the distance externally; and by injecting warm water and noting its capacity, washing it out and seeing what effect this has upon the distension.

(To be continued.)

—A physician called to attend a sick person in Reading, Pa., recently reported that the house containing four rooms, was occupied by "seventeen persons and eight dogs."

MEDICAL SOCIETIES.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

The Bacillus Tuberculosis and the Etiology of Tuberculosis. Is Consumption Contagious?

BY H. F. FORMAD, B. M., M. D.

(Continued from page 297.)

Koch asserts that the structural peculiarities of the tissues which I described can have no etiological relation to tuberculosis, because an animal not possessed of such tissue peculiarity—the cat—is easily inoculable by tuberculous material. Here I must differ from Koch, as in my experience with cats this is not the case; and, again, Koch brings no proof for his assertion, and I am unaware that he, or anybody else, produced tuberculosis in a cat, except by inoculation into some serous cavity. That inoculations into serous membranes prove nothing for tuberculosis, as I have shown conclusively, Koch still seems to fail to see. But here is a way in which cats may become tuberculous, with or without the bacillus. In one instance, we kept one of the cats in a close box, *deprived* of liberty, good air, the comforts of life, motion and sufficient food; she also had been inoculated with diphtheritic material eight months previously, but had recovered. After the lapse of a year, the cat was set free; but was accidentally killed, and was found to be affected by general tuberculosis in a high degree.

This, in my opinion, corresponds fully to the conditions in which a healthy young woman is placed, and finally becomes scrofulous, and then tuberculous, from a simple cold, after being the faithful nurse for a couple of years of a consumptive husband.

On the other hand, there is full reason to believe, as it is in accordance with experience, that young scrofulous persons, under proper conditions, may become normal individuals; *i. e.*, lose or outgrow the predisposition to tuberculosis. (I have dwelt upon this in my first communication on this subject.)

The scrofulous habit, and consequently also phthisis, may skip a generation, and does not invariably embrace all members of a family. It has been observed that parents may have at first healthy children without any vice, who grow old well; and subsequently the same parents, without being phthisical (but perhaps otherwise becoming deficient in health), may have other children that exhibit a full scrofulous habit. But even the reverse has been observed.

It would be highly desirable if physiologists would furnish some experimental observations on the circulation of the plasma in the lymph-spaces. This is, to my mind, a circulation or movement of vital juices in the tissues, which, for the well-to-do of the individual, is of importance next to that of the blood. These important channels, the lymph-spaces, are known to regulate the blood-pressure, carry and breed (white blood corpuscles) food for the tissues, lubricate tissue, and relieve the body, if any of its parts are damaged by injury of any character, of inflammatory exudates, dropsy, etc. These channels are nearly blocked up, nearly useless in the *scrofulous*, and hence cannot perform their functions; and thus modify

materially the condition and the fate of the individual, in case of disease.

The term "*scrofulous*," which I retained for describing the above-stated anatomical peculiarity of animals and individuals, is as good as any other term; moreover, it is known by all as designating the "predisposition" to tuberculosis. Scrofulosis should be called a *condition* and not a disease, as it has its (a natural) hereditary and widely-distributed type in man, and its homologue in some normal animals (rabbit, guinea-pig, etc.). It must be remembered that the scrofulous individual acquires certain lesions, such as enlargements of the lymphatic glands, cold abscesses, caries, long standing catarrhs of various kinds, skin eruptions, and certain deformities of bones, only under the influence of injuries, or of the same agencies which, in the non-scrofulous individual, lead to transient and curable affections.

Virchow designates simple, permanent enlargement (hyperplasia) of lymphatic glands, with or without cheesy change, "*scrofulous*" in contradistinction to "*tuberculous*" lymphatic glands, which contain miliary tubercle nodes (heteroplasia), and which also undergo cheesy change.

There is nothing called "*scrofulous*" or "*scrofulosis*," which by others is not also called "*tubercle*" or "*tuberculosis*." There are, strictly speaking, no scrofulous products, but only tuberculous products. The traditional term "*scrofulosis*" is variously used and interpreted, although it is not evident that any one means by it anything anatomically well defined.

Others take matters easier, calling everything *tuberculous* that contains tubercle bacilli, and calling scrofulous all cheesy matters in which bacilli are absent.

There is still a third aspect of this question, viz., the parasitic or bacillary theory of the predisposition to tuberculosis. As I mentioned in the earlier part of this paper, Baumgarten, Marchant, and several others, recently brought forward that not only tuberculosis, but that even the predisposition to tuberculosis is to be explained by the susceptibility of an individual to bacilli! Under this hypothesis, the scrofulous tendency in individuals is created through the mediation of the bacilli. It is supposed that the bacilli or their spores may be conveyed to the ovum by the organization of the mother, or in utero by the spermatozooids of the father. Furthermore, they say, inheritance is to be explained in no other way than by a bacillary infection of the infant through the milk of the nursing mother, and by subsequent living together of children and phthisical parents. We may exclude such view altogether from consideration, as it has not been proven. Besides, it is not in accordance with facts from observation. It is as contrary to biological laws to accuse parasites for the transmission of a predisposition to tuberculosis, as it would be for that of epilepsy, etc. Hence, we may dispose of such view as an unfounded, absurd hypothesis.

I am not opposed to the germ-theory of disease, where it has its well-founded and proper application. Bacteridian studies have contributed largely to our knowledge of a certain class of pathological processes and lesions. But misinterpretations of

the significance of bacteria; bacillary speculations, without occasion for them and without any proper application to the subject, are a check to the progress of medical science. The question of the predisposition to, and the cause of, tuberculosis, demands a great deal more of solid pathologico-anatomical and experimental studies; it can, by no means, be regarded as settled, and least of all through the discovery of a bacillus inhabiting necrotic tubercular tissues.

3. Tuberculosis, without Predispositions, Due to Inflammation of Serous Membranes.

For some years I felt much interested in the question whether or not simple inflammation of serous membranes could lead to tuberculosis in the non-scrofulous, that is, in persons which have no family history of tubercular disease; and I would like to ask the opinion and experience of the members of the Society upon this question. It is well known that there may be primary tuberculosis of serous membranes, producing secondary inflammations; and, on the other hand, tuberculosis secondary to adhesive pleurisy or peritonitis is also common in serous membranes. The general belief, however, is that whenever tubercular disease in either case occurs, if not secondary to phthisis or tubercular disease elsewhere, a strumous or scrofulous condition is required.

Traumatic injuries of joints are known to lead often to fungoid (tubercular) synovitis and general tuberculosis, occasionally in individuals with good family history. Simple injuries of the eyeball (the anterior chamber as well as joints is lined by serous membranes), under conditions as above stated, have also been known to lead to tuberculosis, as recorded by Wolfe (*Brit. Med. Jour.*, March, 1882); Gradenigo (*Annale d'Oculistique*, 1870).

Dr. M. Litten,* of Berlin, was the first to publish some accounts which demonstrate that miliary tuberculosis may be caused directly and primarily by pleurisy and inflammation of other serous membranes in persons with no phthisical history, and without any cheesy masses being formed in any part of the body. In his (Litten's) experience this was particularly the case when there was a rapid reabsorption of the exudates in case of chronic pleurisy, or if repeated removal of the fluid of a hydrothorax or ascites by tapping has been performed. He records several well-studied cases of that kind, accompanied by autopsy records. Litten's observations at no time, however, received their well-deserved attention.

Not only clinically, but also pathologically, this part of the tuberculosis question is rather neglected. In text-books of pathology the occurrence of primary tubercle in adhesive bands is incidentally mentioned, but no special consideration is devoted to its etiology and manifestations.

Upon the autopsy table I have repeatedly met with subjects with exquisite primary tubercular peritonitis, pleurisy or pericarditis, which, upon

*M. Litten, Sammlung Klin. Vorträge, No. 119. Ueber acute Milartuberculose, 1877. For further references see Wiener Med. Presse, No. 36, 1882 Charité Annalen, vol. vii, Berlin; Krankheiten der Respirations-Organen, in Virchow's Handb. der Spec. Path. und Ther., vol. i.; Virchow, Geschwulste, vol. ii., p. 725, etc.; also, Formad, Transactions of the Philadelphia County Medical Society, and of the Pathological Society, for 1882-83.

inquiry into the history of the cases, failed to reveal any phthisical or scrofulous history. The products of these inflammations were often plastic in character, not unlike those of fungoid synovitis. The appearances sometimes present themselves particularly strikingly in the peritoneum; all the viscera may be glued together by plastic material into a solid mass. The omentum is usually retracted and matted together into a solid cord or mass, which, lying parallel with the transverse colon, reaches across the abdominal cavity, and may have a thickness of from two to four inches; the mesenteric and other lymphatic glands are usually normal, but sometimes in advanced cases may be much enlarged, and more or less cheesy. The perfect absence of any cheesy focus in the body is, however, often a conspicuous feature in these cases.

Some pathologists deny the tubercular nature of these formations, and of the flat nodular masses which cover the serous surfaces in these cases. It is true that fibroid changes predominate in these formations; but numerous tubercle nodules, with all the necessary attributes, epithelioid and giant cells, and necrotic changes, were plainly seen in all cases which I had occasion to examine. Secondary miliary tubercles of quite recent date are also found thickly strewed locally in these parts, and may or may not be seen in the lungs and other organs. As a rule, there is more or less ascites in these cases. My colleague, Dr. E. O. Shakespeare, has recorded similar cases, and Dr. Morris Longstreth tells me also that he had seen and studied such cases. Dr. Mitchell Prudden describes (*New York Med. Record*, June 16, 1883,) an allied case.

In chronic adhesive pleurisy there occur similar primary tubercular formations in the organized plastic exudate, which in some cases gives rise to secondary (miliary) tuberculosis of other organs. The lungs may be perfectly normal in all parts, and show only peripherally, just below or bordering the pleura, some indurations of gray color made up of recent tubercle tissue. These young tubercle infiltrations are in some cases seen to have penetrated into the substance of the lung, like in a pleuro- or dissecting-pneumonia, directly from the old tubercular masses of the adjacent pleural membrane.

I have also examined several cases of plastic adhesive pericarditis, and found the plastic vegetations in this lesion to contain tubercles; two of these had coincident pleuritic lesions.

Cases which came under my observation during the last eighteen months—i. e., since the opening of the bacillary campaign—were, of course, carefully examined for bacilli, and the results may be summarized as follows: bacilli were found in most of the lesions, if the tubercular disease of serous membranes was accompanied by cavities and cheesy masses in the lung, or by tubercular ulceration of the intestines, and if cheesy changes in general were prominent; but no bacilli could be discovered, even after repeated and careful search, in any of the lesions of four cases of primary peritoneal and pleuritic tuberculosis examined. In none of these latter four cases were there any conspicuous cheesy changes in any organ, and no cavities or marked hepatizations in the lung, and no intestinal ulcers, although in two there was

slight pulmonary miliary tuberculosis. These cases will be recorded in detail in a future publication.

I have also seen several cases of primary tubercular pleurisy and pericarditis, and a few of primary tubercular peritonitis, in the pathological institutes of Virchow in Berlin, and of von Recklinghausen in Strassburg. I questioned these foremost men of pathology concerning the etiology of these lesions. They, as well as Rindfleisch, of Würzburg, told me personally their opinion, stating their firm belief that these lesions often directly originated from simple chronic inflammatory changes, without the agency of any cheesy focus, or any specific agencies whatsoever.

Birch-Hirschfeld also states, in his classical pathological work (page 183), that "nearly every exudative pericarditis, and pleurisy leads to a local tuberculosis, if it takes a chronic course."

How often primary tubercular lesions of serous membranes occur in non-scrofulous persons, and whether this is the only form of tuberculosis in this class of persons, is, of course, a matter of speculation, until thorough statistics and careful studies are made in this direction. Nevertheless, it is a demonstrated fact, as I will show further on, that primary tuberculosis can be produced in the peritoneum of animals, like the dog, which are proved not to have any scrofulous tendency. I have seen this myself, and have seen O. C. Robinson, in my laboratory, succeed in this experiment, by the introduction of simple irritants into the peritoneal cavity. Koch also never succeeded, even with the bacillus, in producing tuberculosis in the dog, except when using the peritoneal cavity or the anterior chamber of the eye (which is also a serous sac) as a point for inoculation.

Here is room for hypothesis. I would prefer to believe that tuberculosis could occur only in scrofulous persons, as this would better agree with the *scrofulous anatomy*. It is, however, possible that a scrofulous anatomy of the tissues may be artificially established by the blocking up of the lymph-spaces of the serous membranes, by fibrine and molecular *débris*, suspended in the serum, which is being reabsorbed. This would then be a mechanical process, and not one of infection. If an inflammation occur in serous membranes, resolution becomes difficult through the peculiarity of the exudate. This is fibrinous mainly, and forming extensive, usually permanent organized deposits, it impairs the function of serous surfaces quite materially; the reabsorption of new exudates is probably sometimes entirely impossible. Thus conditions may possibly be created in serous membranes, not unlike those of scrofulous tissues; and simple irritants, perhaps the fibrine, may induce in them a similar reaction.

4. Question of Contagiousness. Clinical Aspects.

The idea of the contagiousness of tuberculosis is not new, and, like other unfounded views in medicine, it has oscillated, like all fashions will, from one extreme to another for many generations. At present it is entertained by a number of scientists, and by a part of the profession. This view has called forth, from time to time, a number of researches whose results were either pro or contra. I will refer to these subsequently.

Of late, it appears that the belief in the con-

tagiousness of tuberculosis has won considerable ground, not so much on account of accurate observation as on account of Koch's discovery of the bacillus tuberculosis.

Another element, which seems to have had an influence in this direction, is the fact that certain experimenters, formerly believing, from their own experiments, that tuberculosis was non-contagious, were led, later on, to change their opinions on account of the results of subsequent experiments. These latter experiments will, however, be shown not to be conclusive.

Before discussing the merits of the bacillus question, I would like first to consider the question of contagiousness from clinical grounds; and should it be proven that tuberculosis is not contagious, then the necessity for a contagium surely falls to the ground.

According to the observations of the most prominent clinicians who have paid special attention to this matter, there is not a single authenticated case of tuberculosis as a result of contagium on record. Among scores of experienced men who deny thus the contagiousness of tuberculosis, it is sufficient to mention the names of Virchow, v. Reclinghausen, Stricker, in Germany; Gull, Williams, Watson, Paget, Humphrey, Richardson, in England; Bennet, in France; and Hiram Corson and Traill Green, in our own midst—all men of close observation, with ripe experiences reaching over thirty to fifty years.

The statistics of the large Brompton Hospital for Consumptives, for thirty-six years, with regard to the resident officials, compiled by Dr. F. Williams (quoted after the *Lancet*, 1883), shows that of four resident medical officers, one of whom had served twenty-five years, none had any lung disease; of six matrons, none were consumptive; of 150 resident clinical assistants, eight became consumptive, and five died, but in only one was the disease developed during residence at the hospital. Since 1867, of 101 nurses, only one died from phthisis, and that after leaving the hospital. Before 1867, six died, three of these of phthisis, but only one became so whilst resident, and she had a consumptive sister. She died thirteen years after first joining the hospital, but was not there the whole time. Of thirty-two gallery maids since 1867, none developed phthisis whilst at the hospital. Of twenty house-porters, five died, but none of consumption. Non-residents:—Of nine secretaries, three were threatened with lung disease, but recovered. Of twenty-two dispensers, seven died, three of phthisis, one while at the hospital. Of four chaplains, three died, none of phthisis. Of twenty-nine physicians and assistant physicians, eight died, none of phthisis. At the Chest Hospital, Victoria Park, there have been five resident medical officers during about the last fifteen years; all are alive and well. Two matrons, neither consumptive. There were two clinical assistants appointed every three months: none known to have developed the disease at the hospital. One nurse out of fifty or sixty in the last few years became consumptive while at the hospital, and she died after a year's illness.

An ingenious plan to decide the question of the communicability of phthisis was instituted by the British Medical Association by establishing the Collective Investigating Committee. This com-

mittee sent out questions relating to this subject to all the members of the Society. Of 1028 replies received, 673 negatived the idea of a contagium, while 261 replies favored it. According to these statistics, there is a manifest majority in favor of the non-contagiousness of phthisis; yet such a plan is unsatisfactory, as the answers may be of unequal value, as their worth must be estimated in proportion to the experience and authority of the sender.

Not without interest is the observation of Prof. Corradi, of Pavia, who noted that out of 133 families in which he had cases of consumptives, in only twenty-five of the families were there more than one member of the family ill of that affection.

There is no proof whatever that tuberculosis is conveyed from person to person by contagion. Seeming exceptions to this assertion can almost always be accounted for in some other way.

The assertion that the wife may contract the disease from the husband, I have pointed out in a former paper to be untenable; and I have also indicated that a predisposition to scrofulosis may be acquired from the unwholesome mode of life led, of necessity, by such individuals. Besides, it is established statistically that nearly one-third of all deaths occurring in middle life are due to phthisis. In view of the frequency with which this malady occurs, intermarriage between scrofulous individuals may be almost as common as between non-scrofulous ones.

The view taken that children become scrofulous by contagion from phthisical parents, may be met by the fact that instances have occurred where a number of young children of phthisical parents were early removed from their homes and distributed among healthy families, and yet all, sooner or later, became phthisical.

Healthy persons have even been fed on bovine tuberculous material (which is considered identical with human tuberculous material) and have thrived on it, as is proven by the interesting feeding experiments made upon man and recorded by Schottelius (Virchow's Archives, No. 91, 1883). The circumstances which led to this experiment were as follows: In Würzburg, the sale of meat affected by pearl disease or bovine tuberculosis is permitted, but, as some opposition to the sale once arose, a community of country people agreed to use exclusively tuberculous meat, on account of its cheapness, and in order to prove that it was harmless. From October 1867, to November, 1868, forty-nine tuberculous beeves, with well-pronounced lesions, were consumed by these people while they were under the supervision of the district physicians. In many instances the meat was even eaten raw in consequence of habit. Ever since then, those people have continued the use of tuberculous meat, and thus far no bad results have been noticed; in fact, the record says that the people referred to are unusually healthy.

—Dr. Dehenne writes in *L'Union Médicale* on the surgical treatment of interstitial keratitis. He recommends the performance of an iridectomy. Iridectomy, he avows, cures the disease in some days, and consequently confers immense benefit on the patient.

EDITORIAL DEPARTMENT.

PERISCOPE.

The Etiology, Pathogenesis, Treatment and Prophylaxis of Pulmonary Tuberculosis.

The *London Med. Record*, February 15, 1884, tells us that Prof. Sormani contributes an important and interesting article to the *Annali Universali di Medicina*, September, 1883, under the above title. The numerous observations now recorded in many countries confirm the importance of the discovery of Koch, of the bacillus of tuberculosis, in diagnosis and prognosis. The presence of the bacillus in the sputa, pus, and other secretions, and in the tissues and organs, is a certain indication of the tubercular process, and is sufficient to establish its diagnosis. The absence of the bacillus in the excretions, if repeatedly confirmed, with rare exceptions only, renders it certain that the affection is not tubercular. If the bacilli be abundant, long, sporigenous, and in groups, there is an active proliferation of the micro-organism, and the disease will probably run a severe and rapid course. For the microscopic examination of the bacilli the author prefers Ehrlich's method, modified by Weigert. A thin layer of sputum, spread on a cover glass, is dried over the flame of a spirit lamp, and then immersed in the solution of gentian-violet (Weigert's formula: gentian-violet, 1.5 parts, dissolve in 15 parts of absolute alcohol, add 3 parts of oil of aniline, and dissolve in 100 parts of distilled water.) It should remain in this solution for fifteen or twenty minutes, or longer; it is then rapidly passed into dilute nitric acid (50 per 100), then into alcohol, and then into a weak aqueous solution of vesuvine, and, lastly, well washed in absolute alcohol. The preparation may be mounted in oil of cloves, castor oil, or dammar varnish. Sections require three or four hours to take the color, and should generally be allowed to remain twenty-four hours.

Prof. Sormani has made many experiments on the inoculation of animals with tubercular matter. The results of these experiments are published in the *Rendiconti del R. Istituto Lombardo*, July, 1883. Inoculation with sputa containing bacilli gives rise to tuberculosis, which is developed more rapidly when the bacilli are abundant. The inoculated bacillus multiplies in the organism, and invades the lymphatic system, liver, spleen, and serous membranes; by its presence it sets up a chronic inflammatory process, with formation of products which become caseified, and subsequently soften, producing gradual destruction of the organs. The bacillus is found in the centre of the tubercles in their earliest stage of formation, and hence is the cause and not the effect of the morbid process. The lymphatic vessels, amœboid cells, and the blood-current, are the means by which these micro-organisms are transported from one organ to another and diffused throughout the body. Koch's discovery gives us a new indication as to treatment. It is reasonable to suppose that a substance may be found which, while innocuous

to the individual and to the function of the diseased organ, may act on the bacillus or its substratum, and so arrest its proliferation.

Recent studies on the artificial culture of morbi-genic germs and other micro-organisms, show that these organisms are very capricious, and that it is sufficient to modify very slightly the cultivating menstruum to arrest their proliferation. In the artificial cultivation of the *aspergillus niger*, an infinitesimal trace of nitrate of silver renders impossible the vegetation of this microscopic fungus (Duclaux, *Ferments et Maladies*). The problem is to find some substance which, while harmless to the system at large, may yet prevent the growth of the tubercle-bacillus. Many antiseptics have been tried to this end. The fumes of sulphurous or nitrous acid are fatal to the bacillus, but are not respirable. Corrosive sublimate in a solution of 2 per 1,000 does not destroy the bacillus (Vallin).

Iodoform has been tried in many ways. The author gives it internally in the dose of 50 centigrammes daily, and by inhalation in the following manner: A Woulff's bottle with two necks is taken; into one neck is inserted a glass tube, which reaches nearly to the bottom of the bottle; into the other a short tube is placed, which is connected with an India-rubber tube, having at the other end a respiratory mask; to the longer tube is fastened a cylinder containing compressed air (Waldenburg's apparatus. *Die Pneumatische Behandlung*: Berlin, 1876). In the bottle is placed about 50 grammes of iodoform, previously finely powdered, with the addition of a little ether. When the apparatus is used, the compressed air passes through the Woulff's bottle, and the strong current of air takes up a part of the iodoform and carries it into the lungs. To facilitate the volatilization of the iodoform, the bottle may be placed in water and heated up to 100° (decomposition of the iodoform only takes place at 120°). The greater part of the iodoform inhaled is arrested in the bronchial tubes, but in animals some reaches the alveoli themselves. At first one only of Waldenburg's cylinders a day was used; the number was gradually increased to ten. The iodoform was never irritating; it was absorbed, and could be recognized in the urine by nitric acid and sulphide of carbon. After about a month of this treatment, the patients had notably improved; fever and night-sweat had disappeared; and the cough and expectorations were much diminished. In three months they had gained from 5 to 12 kilogrammes in weight, but the bacilli had not entirely disappeared from the expectoration. The great diminution of the expectoration, however, proved that the proliferation of the micro-organism was much less active. The local mischief was arrested; the vital capacity of the lung was rather diminished than increased; and this is in harmony with the fact that cicatrization is taking the place of the destructive process.

Koch's process to prepare the gelatine for the artificial cultivation of the bacilli takes a week or

more. Dr. Sormani finds that it can be quite as well and much more quickly obtained by heating in a water-bath calf-serum previously filtered and rendered alkaline by the addition of crystallized carbonate of soda. His best cultivations were made with this gelatine in watch-glasses, soldered together with mastic and silicate of potash. Out of sixty attempts, in six only were developed the little greyish-white, sometimes yellowish, patches described by Koch; these patches contained very numerous oval spores, united in zoogloea, and immovable, of uniform size, the greatest diameter being one micro-millimetre. On the addition of a liquid, the peripheral spores become detached, and acquire a vivacious oscillatory movement. Later appear very fine transparent oscillating bacteria, two to seven micro-millimetres long, or even more, articulated, granular, and, like the spores, strongly coloring with gentian violet. Among the spores and bacilli, numerous crystals of chloride of sodium and carbonate of soda were visible. The uncertainty still existing as to the value of the spores and bacilli obtained as the products of cultivation, and the great tendency of these cultivations to fail, render it premature to decide on the efficacy of the various therapeutic agents from the negative results only obtained by artificial cultivation.

Dr. Sormani agrees with Marchiafava that the bacillus is not found in the breath of the phthisical. The bacillus is preserved unaltered in the expectoration for a very long time, and resists putrefaction and desiccation, and preserves its virulence. Tuberculosis is not directly contagious, but indirectly it is, by means of the dried, powdered tubercular sputa which float about as dust in the air.

In the prophylaxis of tuberculosis, the prompt destruction of tubercular sputa, and the efficacious disinfection of the rooms and objects soiled by tubercular matter, must be chiefly insisted on.

A Clinical Observation in Support of the Theory of the Contagiousness of Pulmonary Consumption.

Dr. Frank Ogston thus writes in the *Brit. Med. Jour.*, February 2, 1884:

From all that could be learned of the family history of Mr. and Mrs. G., no suspicion of an hereditary tendency to consumption could be traced; on the contrary, both his and her forefathers had been noted as being healthy and long-lived, and they themselves, at the ages of fifty-seven and fifty-five respectively, are quite hale and strong. Their family consisted of six sons and two daughters, between the ages of thirty-one and twelve; and they had been strong and healthy children, with no apparent tendency to disease.

About three years ago, the third son (George) caught cold, as it was said, and came from his home in Glasgow, where he was living with his wife, to be nursed in his father's house in Aberdeen. He was examined by a medical man in town, who stated that he was suffering from pulmonary consumption; and he died about two months afterwards. The accounts of his illness leave no doubt that the disease was correctly diagnosed, and that it had run its usual course.

There is an obscure history that some of the

members of George's wife's family had died of consumption; but she had none of the symptoms of it, and was quite well when last heard of.

George had been nursed by his sisters, Kate, aged then about twenty-one, unmarried, and Mrs. B., aged eighteen, since married, who, it is stated, were then both stout, healthy girls.

The first month after George returned to his father's house, a younger brother (Charles), aged fourteen, slept in the same bed with him, but afterwards, for convenience of nursing, went into another room.

Shortly before George's death, Kate began to lose color and flesh; but little notice was taken of her, as it was ascribed to fatigue and grief for her brother.

In July, 1882, I was called to see Mrs. B., who had been married a few months previously, and who occupied, with her husband, part of the same house with her parents. I found consolidation of the right apex, and a larger patch of consolidation in the left apex, which had just commenced to break down. She had an anæmic appearance, but was fairly plump. Her forenoon temperature was generally about 100°, but she had no night-sweats. The paroxysmal cough was the chief source of complaint. The disease progressed rapidly, in spite of cod-liver oil emulsion, Coghill's inhaler, etc.; and, in November, she died in a few minutes from an attack of hæmoptysis. She had become rapidly emaciated, and both lungs were extensively broken down. The sputa, which had become abundant, swarmed with bacilli.

During Mrs. B.'s illness, my attention was called to her sister Kate, who was nursing her, and I found in her also apical consolidation to a slight extent, with rapid pulse and an anæmic appearance. She had no cough at that time, and seemed to improve when ordered hæmatonics and separation from her sister.

During the same summer, a boy came to my house from time to time, complaining much of shortness of breath and weakness. On examining his chest, I found a suspicious dullness at the left apex. I gave him quinine and iron tonics, and he improved for a time. I did not see him for a few months; but one day I found him in Mr. G.'s house, when I discovered that he was one of the family—in fact, Charles, aged now nearly seventeen.

From time to time I visited Kate and Charles, who became gradually worse; and in a few months they died, with all the symptoms of phthisis, within a few days of each other.

There now remain four sons: the eldest, a tailor's cutter, is married, and has two strong and healthy boys; the second, a saddler, is the picture of vigorous manhood; the third, a sailor, who came in point of age between George and Kate, is a strong and vigorous man, who has come through many hardships, having been several times wrecked: "on one occasion, he was in an open boat on the Atlantic for fifteen hours, with no clothing but his night-dress, and then three days with only a suit of oil-skins above the night-dress" (a brother's statement); and the youngest, a boy now of fifteen years, is a draper's apprentice, and is strong and healthy.

Here, then, we have a man suffering from consumption brought into a healthy household, in-

fecting first a brother, who slept with him, and then his sisters, who were engaged nursing him; while his four remaining brothers, who came little into contact with him, escaped. The presumption of contagion seems strong.

Note on the Treatment of Eczema Marginatum, and of Ringworm in General.

Dr. R. W. Taylor thus writes in the *Jour. Cut. and Ven. Diseases*, February, 1884:

I have always placed much confidence in the parasiticide virtues of bichloride of mercury in the treatment of the various forms of ringworm, and have generally used it in alcoholic solution, being in accord with Cavafy in the opinion that, thus used, its efficacy is much enhanced. Even thus combined, its action is not always certain, particularly in cases of eczema marginatum. This fact was very forcibly brought to my mind in the treatment of the case of a young lady during the past summer. She had this affection, severely involving the integument of the hypogastric, pubic, crural, and gluteal regions. The diagnosis was confirmed by the discovery of the parasite in the scales, but the appearances of the eruption were thoroughly typical. I ordered a two-grain solution of the bichloride of mercury in one ounce of alcohol, which was used for about a week, when I increased the strength to four grains, as the progress was not satisfactory. Though the parts were carefully sopped with this solution three or four times a day, and care was taken that the underclothes should be frequently changed, the rings of eruption advanced, in many parts being preceded by outlying papules. The pruritus was only relieved for a limited period after each application. In this state of affairs, it occurred to me that, if I could find some vehicle by which the parasiticide could be kept continually over the morbid surfaces, and not be rubbed off, I could soon effect a cure. It happened one day when the progress of the case was thus at a stand-still, that I had on my office-table a bottle of tincture of myrrh. The thought occurred to me that, if the liquid was painted over the surface, a very thin, flexible layer of gum resin would be left which would retain the bichloride of mercury in contact with the skin. I, therefore, first thoroughly bathed the parts with a four-grain-to-the-ounce alcoholic solution of the bichloride, and, when dry, painted the whole surface with the tincture of myrrh. The lady reported, the next day, that she was much better, and had not scratched very much since the application. I then gave her a prescription containing four grains of the bichloride to the ounce of tincture of myrrh, with directions to thoroughly paint the parts twice daily. The effect was simply wonderful. In a few days, the patches and rings became less rigid, the papules less salient, the pruritus was relieved, and, within a fortnight, the disease was wholly cured. I have since used the simple and compound tinctures of benzoin in the same way, and find that they are equally as valuable in affording a vehicle for the parasiticide and a protective film to the integument. The discomfort of the application of these tinctures is very slight; patients simply complain of a little drawing or tight sensation of the parts, for a few

moments after the application—inconveniences which are more than counterbalanced by the relief of the pruritus. I have thus far used this method in three cases of eczema marginatum and two of tinea tonsurans capitis; in all with most excellent results, namely, a prompt and perfect cure. Whether the gum resins have any therapeutic effect, I am unable to say. I think that these tinctures can be still farther used with benefit as a vehicle for other agents in the treatment of skin affections.

A Ready Method for the Detection of the Bacillus Tuberculosis.

Dr. M. B. Hartzell thus writes in the *Med. Times*, January 26, 1884:

Since Koch first announced the discovery of the bacillus tuberculosis, methods for its detection have multiplied rapidly. Most of these methods, however, are more or less complicated, are uncertain, and require too much time for their execution to be of use clinically.

On account of its simplicity, and of the short time required to execute it, I wish to add another to the many staining processes already in use. This process appears to me to possess decided advantages over all others with which I am acquainted; by means of it the sputa of patients who are supposed to be tuberculous can be easily and rapidly examined, and the bacilli are so deeply stained that if any are present in the specimen under examination they cannot be overlooked, if ordinary care is used. The process is briefly as follows: A small quantity of sputum is spread as thinly and evenly as possible upon an ordinary glass slide; it is allowed to dry, which takes but a minute or two, and is then passed slowly several times through the flame of an alcohol lamp or Bunsen burner. One or two drops of the fuchsin solution, recommended by Gradle, and prepared as follows—carbolic acid, mxv ; distilled water, $\text{f}\text{.}\text{ss}$; dissolve, and add saturated alcoholic solution of fuchsin, $\text{f}\text{.}\text{ss}$ —are placed upon the sputum thus prepared, and allowed to remain from three to five minutes. The slide is now washed thoroughly with distilled water, to remove the excess of fuchsin, and the stained sputum completely decolorized by means of a saturated solution of oxalic acid. It is again thoroughly washed in the distilled water after the decolorization, and allowed to dry. It is now ready to be mounted in glycerin or balsam for examination. With a power of five hundred or six hundred diameters, the bacilli will appear as brilliant red rods, no staining of the background being necessary.

In all other methods with which I am familiar, the decolorizing agent employed is dilute nitric acid; but this, besides being disagreeable to handle because of its corrosive and staining properties, is apt to remove the color from the bacilli too, unless great care is taken. Oxalic acid, however, seems to leave the dye untouched in them.

To render the process still clearer, the different steps may be arranged thus:

1. Spread the sputum upon the slide, dry, and pass through the flame of the lamp.
2. Stain with the fuchsin solution three to five minutes.

3. Wash in distilled water.
4. Decolorize with oxalic acid.
5. Wash again thoroughly in distilled water, dry, and mount in glycerin or balsam.

Bleeding in Delirium Tremens.

Dr. E. J. Kempf reports this case in the *Louisville Med. News*, March 8, 1884:

M., a merchant of the village, called at my office one morning before daybreak, and aroused me. He was in a desperate plight, hatless and coatless; with bloodshot eyes and inflamed eyelids, trembling hands, and a nervous condition of the body. He told me candidly that he had been drinking greatly to excess for the last six weeks, that he had not slept a wink nor eaten a bite for the last sixty hours, and that he felt as if he were either getting crazy or getting the fits.

The patient was a stout, well-built, corpulent man; a high liver, one who had drunk intoxicating liquors more or less all his life. On account of business cares he had lately lost all control over himself, and been, as he himself expressed it, drunk for the last six weeks. I persuaded him to return home, and prescribed rest, small doses of stimulants, liquid, nutritious diet in small quantities, large doses of bromide of potassium and hydrate of chloral alternated, and saline purgation.

The next morning I found the patient somewhat calmer, but with a full, bounding pulse, and temperature of 102° F. His head ached and felt dull, and he seemed apprehensive of some calamity or mishap. He had slept about an hour during the night at broken intervals; he had been bothered very much by dreams and "foolish thoughts." His bowels had moved freely, the feces being watery, blackish and foetid. I advised bleeding, to which the patient readily consented. I accordingly opened a vein in his right forearm, and let blood flow to the amount of fully three pints, when the patient, who was sitting on a chair with a cane supporting his arm, fell from the chair to the floor in a faint. Large drops of perspiration stood on his forehead, and his skin had a cold, clammy feeling; his pulse was now very feeble. We put the patient to bed, and covered him with quilts, and in a short time he rallied. I now ordered absolute rest, milk frequently and in small quantities, and one-eighth grain of morphine every five hours. The patient was in his store two days afterward, asserting that he was entirely well. The marked benefit derived from the bleeding in this case induced me to make a report of it.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT MEDICAL LITERATURE.

—Dr. H. F. Hendrix, of St. Louis, in a reprint before us, describes a remarkable case of arrest of development caused by intra-uterine pressure. He considers that the history of this case will go far to substantiate the theory that most congenital deformities and monstrosities are

to be accounted for by the position which the fœtus occupies in the uterus, and the scarcity of amniotic fluid, in consequence of which the walls of the uterus are allowed to come too forcibly in contact with the embryo, causing it to retain almost any shape which it may accidentally assume.

—A careful report of a case of extirpation of the ovaries by the Battey-Tait operation is given in a reprint from the *Denver Medical Times*, by Dr. Thomas H. Hawkins.

BOOK NOTICES.

Medical Education and the Regulation of the Practice of Medicine in the United States and Canada. By the Illinois State Board of Health. Pp. 270. Chicago: W. T. Keener, 1884.

The publication of this volume will be a public benefit. It was prepared by the Illinois State Board of Health for the fifth annual report of the Board, and has been revised, corrected, and extended for this separate issue.

It contains the laws regulating the practice of medicine in the various States; a list of medical institutions in this country, both those extinct and yet existing; a list of medical colleges, with their course of instruction, fees, number of students, percentage of graduates to matriculants, etc.; auxiliary and post-graduate schools; special lists of colleges for women only, for both sexes, and for colored students; a list of institutions, extinct and existing, which are not recognized by the Illinois Board of Health, as not coming up to the requirements demanded; and other matters.

The reader will easily see that a work of this kind, authoritatively issued, cannot but have a widely beneficial influence.

Illustrations of the Influence of the Mind upon the Body in Health and Disease. By Daniel Hack Tuke, M. D., LL. D., etc. Second American Edition. Philadelphia: H. C. Lea's Son & Co. 1 vol. 8vo., pp. 482.

The growing intelligent interest in the study of psychical phenomena from the point of view of the physiologist, will insure for this revised edition of Dr. Tuke's excellent volume a great many readers. While he does not expressly deny that there are many phenomena which may call for other explanations, he justly claims that whatever can be explained by physiology, should not be placed in any other category.

With regard to this second edition, we do not find much in it not in the first. There are some diagrams added, and moderate notice is taken of several recent publications, but not so much as we had hoped. Those, however, who are not familiar with Dr. Tuke's entertaining pages, will do well

to possess themselves of a copy, and they will find it a real treat.

Eczema and its Management. By L. Duncan Bulkley, A. M., M. D. Second edition. 8vo., pp. 334. G. P. Putnam's Sons. Price, \$3.00.

The reception given to the first edition of this monograph was gratifying to the author, and in the preparation of this second issue he has closely revised his text, and aimed to render it constantly more serviceable to the general practitioner. The frequency of eczema, and its usual ready response to appropriate medication, are reasons which may be offered for the prompt sale of a monograph upon it. The author himself speaks from a study of three thousand cases of it, and of course his experience cannot but be improving to read.

We do not advocate the omission of references to other workers in the same field, all of whom are substantially ignored by Dr. Bulkley. His defense of this omission, as given in the preface, is unsatisfactory; and the result to the reader is disappointing, or else deceptive. "Personal experience," on which he harps, is very good; but, as Bacon says, no sound surgeon is made by it alone; and an author is not justified in ignoring the sources of his learning, and in omitting to credit that which he borrows from antecedent workers.

History of the Discovery of the Circulation of the Blood. By Henry C. Chapman, M. D., etc. Philadelphia: P. Blakiston, Son & Co. 8vo., pp. 56. Price, \$1.00.

This is a lecture, somewhat enlarged, and to be a chapter in a general work by the author. He reviews the subject carefully, and reaches the following chronological arrangement of the epochs of the discovery of the circulation:

1. Discovery of the structure and functions of the valves of the heart. Erasistratus, B. C., 304.
2. The arteries carry blood during life, not air. Galen, A. D., 165.
3. The Pulmonary Circulation. Servetus, 1553.
4. The Systemic Circulation. Cæsalpinus, 1593.
5. The Pulmonic and Systemic Circulation. Harvey, 1628.
6. The Capillaries. Malpighi, 1661.

To this division of the honors of this great discovery the careful historian will no doubt assent. As Dr. Chapman says, it was not the product of one man, but of the gradual progress of scientific observation.

Seventh Annual Report of the Board of Health of the State of New Jersey. 1883. 8vo., pp. 391.

Many interesting vital statistics and much general information are contained in this report. Of the topics discussed, we may mention: the pre-

vention of smallpox, odor nuisances, diseases of operatives, healthy homes, modes of interment, health resorts, charitable and penal institutions, sewage of cities, school hygiene, local boards of health, adulterations of foods and drinks, milk inspection, climatology of the state, and the usual summaries of vital facts.

The Secretary of the Board is Dr. Ezra M. Hunt, of Trenton, N. J., who has done much to promote its efficiency, and who may be addressed for copies.

Transactions of the Medical Association of the State of Missouri for 1883. 8vo., pp. 262.

A well-made volume this, with a goodly array of original articles. Most of the subjects have a living interest, and are well handled. Of these we may mention a study by Dr. P. V. Schenck, of St. Louis, on the comparative mortality, insurability, and proclivity to disease in the two sexes. He gathers together a great many facts indicating the superior viability of the female, and suggests the explanation of this. Dr. J. M. Allen takes considerable pains with his essay, "Alcohol, its Effects upon the Human System;" but shall we never find a writer who can present fairly all sides of this question? Of the undoubted benefits of the substance in its sanitary and hygienic aspects, he says never a word; and if it promotes crime so much, why is there more crime in total abstinent nations than in those that drink? Some striking cases of vaginismus are recorded by Dr. Willis P. King. Dr. J. W. Traver, of Sedalia, advocates the elastic ligature in fistula, and claims good results from it. Dr. W. A. Hardaway reports the results of ten years' observation of electricity in skin diseases. He thinks electrolysis the best cauterant for the skin.

The Diseases of Children. A Hand-book for Practitioners and Students. By Armand Semple, B. A., M. B., 8vo., pp. 352. G. P. Putnam's Sons, N. Y. Price \$1.75.

The author here presents to us a compact and well-prepared manual on this branch of medicine, one which is so important to the general practitioner. He begins with a series of general considerations on the general appearance of infants, their temperament, development, dentition, and on the methods of their clinical examination. From this he proceeds to a discussion of the various diseases to which they are liable, observing necessarily a great deal of brevity, but condensing judiciously. Scarcely any disease is omitted, reasonably full accounts being given of hereditary syphilis, skin diseases, tumors, and scrofulosis. For the purpose intended, the volume is a satisfactory one.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

The COMPENDIUM, formerly published every six months, appears now *every three months*. It is compiled with special reference to being taken *with the Reporter*, and none of the articles which appear in our weekly are reproduced in our quarterly publication. It is made up exclusively from other sources.

Each number of the *Quarterly Compendium* contains 150 pages of reading matter, carefully selected from American, British, and European medical journals, with a special view to the wants of the American physician. It is on excellent paper, and neatly bound in pamphlet form, with full table of contents and index.

The price of the COMPENDIUM is 75 cents a number, or \$2.50 a year; and it will be found well worth it. But when taken with the REPORTER, we offer the two journals at the very low price of SIX DOLLARS, when paid for *strictly in advance* and directly to this office.

LOBELIA AND ITS DOSAGE.

Those of our readers whose medical memory can carry them back a quarter of a century or more, will easily recall the popularity in some sections of the "Thompsonian" medicines, especially "Number Nine" and "Number Two." Except in remote country localities, that "school" has passed away, and its professors have yielded to some other species of charlatans.

Their doctrines were of the simplest. All diseases came either from "heat" or from "cold," these words having some mysterious etiological significance never fully cleared up. The remedy for "cold" was red pepper, for "heat," lobelia inflata, and the amount of these substances poured into the patients was something wonderful.

Though, as we say, the race of Thompsonians seems about extinct in the United States, a number still exist in Great Britain. Our foreign journals contain a notice of a recent trial in London, where a herbalist was charged with manslaughter on the coroner's inquisition, the testimony showing that the patient had died half an hour after taking a tablespoonful of an acetic solution of lobelia prescribed by the defendant.

The defense was that lobelia is not poisonous, and such conflicting evidence from medical men and medical writers was offered that a verdict of "Not Guilty" was rendered. The jury could not do otherwise in the face of such a deposition as the following from a reputable physician of thirty years' standing:

During the whole of that time he had been in the daily habit of using and prescribing lobelia inflata. He had taken it himself in drachm doses. Emphatically it was not a poison. It was an invaluable medicine; there was nothing like it in the whole of the materia medica. To a very delicate child, and in a dangerous condition, he would give a teaspoonful of it in the syrup every three hours. Lobelia was a tonic, an expectorant, a sudorific, and a most valuable emetic. When the Poisons Bill was before the House of Commons, guinea-pigs were obtained from Covent Garden Market, and experiments were made with this so-called poison; but the guinea-pigs would not die from it—they grew fat instead. If lobelia did not act as an emetic, it would be perfectly harmless; it would pass through the body as a gentle aper-

ient; it would not have a depressant effect on the heart. However large the dose, lobelia could not be deleterious.

It is strange that a plant so familiar as this should have its properties so little ascertained. But so it is. Even Ringer, in his work on Therapeutics, attributes its neglect by the profession to the fact that they administer it in too small doses. He would give it much more freely.

Its only danger would seem to be its depressing effects on an abnormally weak heart. The nausea it causes is intense in certain persons, but not of danger or of long duration.

No doubt some of our readers have watched its effects on an extensive scale, and in full doses, and we should be glad to give publicity to their observations.

THE VIVISECTION LAW.

In reference to the facts in this case, referred to in our editorial, cur. vol., p.375, two letters have been sent us, from which we make the following extracts :

From Dr. S. WEIR MITCHELL :

"We, Dr. H. C. Wood and myself, met Mr. Jones, then a State Senator, at his office. He was inclined to favor their bill. We pointed out its absurdities, and said we were willing to accept a bill to restrict, such as was about to be considered by the English Commons, but that it must end all further efforts to abolish vivisection. Mr. J. did not think our proposition would be accepted, or any one which did not mean a step towards total abolition. Next day he told us that the ladies would not entertain our offer. Mr. Jones does not to-day recall what passed."

From the second letter, written by Dr. H. C. Wood, we take the following :

"We [Dr. Mitchell and myself] offered to agree upon a rational bill, similar to that then before the British House of Commons. Mr. Jones, after consultation with the women representing the society, refused to accept any bill not prohibitive in scope, or any modification of the bill then before the Legislature.

"We then, of necessity, used our influence to defeat said bill."

As the source of our information as given in the editorial was directly from the ladies them-

selves, it is quite clear that their representative, Senator Jones, did not apprehend their intentions and wishes correctly, and unwittingly placed them in a position which they did not desire to occupy.

THE SALUBRITY OF WASHINGTON CITY.

Consumption in the Eastern States is like fever and ague out West; every locality acknowledges some cases, but claims that it is much worse in some neighboring district.

The last city which has felt it incumbent upon itself to clear its sanitary reputation is Washington. Our capital, in fact, has always been an apt disciple in that process known in political circles as "whitewashing." A few years ago it was accused of being malarious. Its health officers immediately rushed to the rescue, and demonstrated that all this talk about malaria is nonsense. Then somebody wickedly said that Washington is a hot place in summer. At once, a list of thermometrical readings were published to prove that it is quite a cool spot at that season—favorable, indeed, as a pleasant place of refuge in the dog-days.

Now, some other unbeliever has accused it of showing a very high mortality for phthisis. So far as the bare assertion goes, it is hard to get around it. Here are the official figures, on the authority of Surgeon-General Hamilton :

DEATHS FROM CONSUMPTION IN SEVERAL CITIES.

	Census 1880. Popul'n	Deaths	Year	Average.
District and Washington	177,624	804	1882	1 death in 221
Baltimore	332,313	1,272	"	1 " " 261
Boston	362,839	1,564	"	1 " " 232
Cincinnati	255,780	698	1881	" " 366
Philadelphia	847,170	2,692	1880	" " 314
New Orleans	216,000	900	1881	" " 240
Richmond	63,600	247	1882	" " 257
San Francisco	233,959	690	1881	" " 339

This would seem conclusive. Not at all. The physicians and health officers of Washington are fully acquainted with the celebrated saying of an English economist, "Nothing is so deceptive as figures, unless it be facts!"

They have been making great efforts to show that these numerous deaths are in truth attributable to Washington's famously salubrious climate

—that its reputation as a health resort attracts the consumptives from other localities, and (this is, to be sure, a little awkward) they come and die there!

Another physician puts the mortality on the black race. The white folks, according to an "old and experienced" doctor, have an extraordinary exemption from lung diseases in Washington, where the colored population suffer from it in an equally extraordinary degree.

One of the "oldest" practitioners asserts that the climate there is so healthy that no disease prevails, and as to consumption, if it is common in either race, he has yet to learn it.

It would be rather amusing to read such defences, were it not at the same time a little sad to see how professional men let their opinions be influenced by their prejudices.

NOTES AND COMMENTS.

Sequelæ of Diphtheria.

The sequelæ of diphtheria, as we know, are oftentimes more serious than the disease itself, and Dr. Alfred Carpenter endeavors to explain their occurrence (*Brit. Med. Jour.*, March 1, 1884,) by the following ingenious theory:

"But how will this explain the sequelæ which frequently follow upon diphtheritic mischief? I mentioned the fact that potato-rot is known to be propagated by the agency of resting spores. These are spores or germs which are shut up in a very resistant envelope, which enables them to retain their vitality in adverse circumstances; so that heat, if it be not much above 212° , and the cold even of zero, will fail to destroy it. These spores may, by analogy, be fairly assumed to exist. The ordinary spores are evacuated from the system as the patient recovers; but the resting spores remain in contact with the lining membrane of the blood-vessels, or are carried by the blood-current into some of those parts of the body which usually act as filters, and retain matters which are foreign to the blood-current. Perhaps they attach themselves to lining membranes, such as the valves of the heart. They may there, as they develop, set up ulcerative endocarditis; and being detached from the valves as they increase in size, they irritate the membrane; and, being carried on by the blood-current, they produce emboli at

the spot to which they are carried. There they multiply, sooner or later, and the sequences of the disease appear as if they were separate and independent diseases, and as such are often registered among the causes of death as totally independent of the preceding diphtheritic condition."

Of treatment, he says:

"That treatment has been the use of ammonia as the proper stimulant, so as to reduce the acidity of the blood; for I have generally found these cases in constitutions which are either rheumatic with the lactic acid diathesis, or gouty from the excess of lithic acid in the constitution. I have generally given alkalis, as lithia, or potass. in combination with it; and when there has been an elevated temperature, which has indicated excessive chemical action in the invaded part, I have given the sulpho-carbolate of soda, with the greatest possible benefit. This salt reduces temperature, most likely by its antiparasitic power; for, as soon as a few doses have been given, the fever subsides, and the patient is much relieved; but, if the medicine be left off too soon, there is certain to be a relapse. This is very disappointing, and, if the practitioner be disheartened, and try another remedy, his patient will probably die. But if he return to his sulpho-carbolate, he will ultimately destroy all the developing resting spores in the tissues of his patient, and lead him on to a perfect recovery. It is curious how, in these cases, organ after organ becomes involved in the disease; it is also curious, but highly satisfactory, that the congestions or embolisms follow one another in point of time, otherwise there would be very little chance for the patient to recover. I would urge the practitioner to continue the sulpho-carbolate, in small doses, first with the ammonia, and, after a time, with quinine, avoiding altogether the mineral acids, as such appear to allow a more rapid development of the resting spores and a further relapse.

"As regards the local treatment of diphtheria, I have been accustomed to treat it on scientific principles, and attack the disease just as my gardener attacks the *oidium* upon grapes, and other parasitic disease upon vegetables generally. I apply the powder of washed sulphur to the throat very frequently, blowing it into the fauces, and applying it by means of a brush with a little glycerine or honey, alternating the application with a little sulphurous acid in solution. It is not a painful application; it destroys the mycelium and the ordinary spores which produce the disease. If this be done quickly, so that the growths do not penetrate to the deeper tissues, no

resting spores will find admission to the body, and there will be no following sequelæ. I have also been accustomed to advise that creasote be kept in the room, so that the air may be placed in that condition which diminishes, if it do not destroy, the growth and development of hyphomycetous fungi."

The Antipyretic Treatment of Typhoid Fever.

There are very few instances in medicine where, with quite a satisfactory knowledge concerning the diseased processes in question, our therapeutics are so varied as in the case of typhoid fever. Dr. William Cayley publishes a paper in advocacy of the antipyretic treatment in the *Brit. Med. Jour.*, March 1, 1884:

"Dr. C. stated the principal conclusions which the advocates of the antipyretic treatment of typhoid fever believed to be established on sufficient evidence. First, they maintained that this mode of treatment fulfilled the physiological indications; that, by keeping down the temperature, the febrile metabolism of the tissues, and the accumulation in the blood of the products of this metabolism—and to this Dr. Murchison attributed most of the symptoms of the typhoid state—were much diminished. The granular infiltration and softening of the central nervous system, of the heart, of the liver, of the kidneys, of the voluntary muscles, was to a great extent prevented; and, by the stimulating effect of the treatment on the vaso-motor system, that want of tone and general relaxation of the arteries which was so marked a feature of the disease was counteracted. Many of the opponents of the treatment admitted these conclusions, though, by so doing, they gave up more than half the field of battle. It was not, of course, necessary to assume that the high temperature was the only or even the chief injurious agent in typhoid fever. It was enough to say that it was an important factor, which could not be denied; and it was one which it lay in our power to counteract.

"Secondly. They maintained that, where the treatment was efficiently applied, it produced a marked alleviation of the symptoms. And this, too, was acknowledged by many of the opponents, though by so doing they gave up the greater part of the remainder of the ground. Where the temperature was kept steadily down, the so-called typhoid symptoms were seldom seen. The persistent headache, the febrile oppressions, the sleeplessness, the muttering delirium, the stupor, the dry, glazed tongue, the muscular twitchings, the bed-sores, were either prevented or alleviated;

and, to quote the words of Dr. Austin Flint, who was here endorsing a statement of Liebermeister, the old picture of the typhoid case was no longer to be seen, and the disease had lost half its terrors. Dr. Austin Flint, it was hardly necessary to say, was no enthusiast blinded by his eagerness for this method.

"Thirdly. It was maintained that, by this method of treatment, the complications of typhoid fever were neither rendered more frequent nor more severe. With regard to the pulmonary complications, the hypostatic congestion and pneumonia, there could not be a doubt but that they were rendered much less frequent. With regard to the intestinal complications, hemorrhage and perforation, Dr. Brandt asserted that, when the treatment was applied from the very first, they, too, were much diminished, and it was only reasonable to suppose that, as the tissues were less degenerated and softened, they would be more capable of resisting the sloughing and ulcerating processes. But, when the treatment was deferred till after the lapse of the first few days, it did not appear to exercise much influence, but there was no evidence that these complications were rendered more frequent.

"Lastly. It was maintained, and on evidence that could not, he thought, be overthrown, that by this method the rate of mortality was greatly diminished; so that, when arguments were brought against it, on theoretical grounds, by those who had never tried it, or on practical grounds by those who had only given it an imperfect trial, we might simply reply, with Professor Jaccoud, 'Nevertheless, while the rate of mortality in typhoid fever under the old method of treatment is about 19 per cent., under the antipyretic mode it is under 11 per cent.'"

The Therapeutics of the Lochia in Puerperal Affections.

Writing on this subject in the *Jour. des Sci. Med. de Lille*, Dr. Eustache says that these procedures consist of:

1. Avoiding the retention and stoppage of the flow in the uterus, or vagina, or at the vulva.
2. Modifying, by topical applications of liquids, the state of these surfaces, if they are injured.
3. Also modifying secondarily, by the same means, the offensive qualities of the discharge.

From this it is evident that these means should be employed whenever there is any lesion of the genital passages, especially in metritis; and they should be employed as often as possible before the morbid process has invaded the deeper parts, the

tubes, ovaries, and peritoneum. To fulfill these indications, the means are:

1. *Ergot*, which, given in small doses, two or three times a day, prevents the retention of the lochia.

2. *Intra-vaginal injections*, for which he preferably uses a solution of carbolic acid (1 to 100). The irrigations are made morning and evening, one or two being used until the liquid returns clear.

3. *Intra-uterine injections*, which should only be used when there are symptoms of metritis. For these Dr. Eustache uses the carbolic solution (1 to 100), at 86° to 89° Fah., and an irrigator holding a quart, to the tube of which he fastens a rubber tube, or an ordinary double-current tube. The tube is carried into the uterus to the depth of two or three inches. The irrigation should occupy from five to ten minutes.

Kreochyle.

Kreochyle is a new preparation of meat, made at the suggestion of Prof. Barff, and intended as a dietetic remedy in cases of acute disease, vomiting of pregnancy, aggravated dyspepsia, infantile diarrhoea, and similar conditions. The following analysis has been made by Dr. North, lecturer on physiology at the Westminster Hospital:

	Grammes per litre.
Soluble albumen,	35.125
Potash,	14.19
Phosphoric acid,	2.016
Nitrogen, in the form of kreatin, kreatinin, etc.,	2.4998
Chlorides,	6.186

The residue of meat, after having been used for the preparation of kreochyle, consists of

	Per cent.
Soluble albumen,	nil.
Phosphoric acid,	.704
Potash,	.181

Together with all the fat, fibrin and gelatin.

The *Birmingham Medical Review* concludes that kreochyle, therefore, is superior to beef tea, as it contains not only the extracts but a large amount of albumen. It is pleasant to the taste, and has proved valuable in the hands of many practitioners.

Acetonæmia and Diabetic Coma.

In the *Progrès Médical* (Nos. 50-51, 1883), MM. Cornillon and Mallat argue on the strength of one closely observed case against the theory that the comatose state in diabetes is due to the presence of acetone in the blood. Commenting on this statement, the *London Med. Times*, January 19, 1884, says:

With their opening assertion, that coma is a rare termination of diabetes, we fancy that physicians in this country will not be disposed to agree, for it is generally regarded as the most common termination of diabetes in young subjects. Less objection certainly can be taken to their conclusion, that acetonæmia cannot be considered as the direct and absolute cause of diabetic coma; this accords well with the opinions expressed when the subject was under discussion at the Pathological Society not long since. The authors further conclude, also, that the reddish-brown tint imparted to the urine by the perchloride of iron, and the rose tint by sulphuric acid, may be obtained in cases of long standing diabetes quite apart from any coma. These reactions bear no direct ratio to the amount of sugar present in the urine, and they are not usually found in fat diabetic patients; distillation or an intense and prolonged exposure to heat prevent these reactions; cold has not the same effect. In healthy persons, as well as the subjects of diabetes, perchloride of iron produces in contact with the saliva a reddish-brown color.

Post-Epileptic Automatism.

The phenomena oftentimes observed in connection with the epileptic state are most remarkable, and to a considerable degree is the following case, reported by Dr. T. Clifford Allbutt, in the *Brit. Med. Jour.*:

"A young gentleman who is now under my care for epilepsy of the ordinary type, went with two ladies the other day to make an afternoon call. After sitting awhile, he rose from his chair, and one of his friends said to the other. *sotto voce*, 'Oh, — is in a fit.' This she knew by his face. To her surprise, he went to the tea-table, helped himself to tea, and then walked—full cup in hand—to a chair in another part of the room. When seated again, he recovered consciousness. My patient assures me he was utterly unaware of his act or acts, and was very much startled to find himself transferred in no time, as it were, from one seat to another distant one. It was rather by chance the matter was named to me, and the circumstances were too trivial to encourage exaggeration. The story is, doubtless, quite true, and proves once more the possibility of a series of purposive acts in epileptic states."

Complicated Pregnancy.

In view of the fact that such cases are liable to occur to any one at any time, the following, which

Dr. W. F. O'Grady reports in the *Brit. Med. Jour.* for February 23, 1884, possesses interest:

A woman was admitted, about six years ago, into the Manchester Workhouse Hospital, New Bridge street, who stated that about three weeks before, being at the time three months pregnant, she fell downstairs, and soon afterwards noticed that her belly grew very full. She grew larger daily, and made a fair amount of water; but, when doing so, had to push the enlargement to one side. On examination, there was a pear-shaped tumor reaching to the umbilicus, tense, fluctuant, and dull on percussion. On passing a catheter, 100 ounces of water were drawn off. The gravid uterus was found to be retroverted; this was reduced, and the woman kept prone for a week. I delivered her of a fully-developed healthy child some months afterwards. The medical man under whose care she had been for a fortnight, sent her in as a case of tumor of womb or ovaries, requiring tapping.

Poisoning by Red Precipitate.

Dr. E. Kennedy thus writes to the *Brit. Med. Jour.*, January 12, 1884:

In the text-books accessible to me, there are but two instances cited of poisoning by red precipitate, and scarcely anything stated as to treatment. It would appear, then, that this agent is rarely chosen by the suicide or homicide; hence, it may be worth while to place on record a case recently occurring in my practice. A woman of middle age swallowed twopennyworth (about two drachms) of red precipitate. On my arrival she was vomiting, salt and water having been administered by her husband. I administered an emetic of sulphate of zinc; afterwards raw eggs, magnesia in milk; the diet to consist of egg in milk, bread and milk, etc. The symptoms complained of were, epigastric pain of a burning character, and an indefinite feeling of pain diffused over the abdomen. The next day there was hæmatemesis, and passage of florid blood *per anum*. After this the discomfort gradually subsided, and in five days the patient was convalescent.

Lead Poisoning.

One would hardly expect to find the origin of lead poisoning inside of the kitchen boiler, but so it was in a case that is reported in one of our foreign exchanges. Repeated and careful examinations failed to reveal any cause for the evident symptoms of lead poisoning from which the family were suffering. Finally, upon examining the kitchen boiler, a quantity of red lead was found

therein. A new tap had some few months before been put in the boiler, and one of the workmen had carelessly thrown in a large lump of red lead, which was left over when they had finished the job, in order to get rid of it. Here, then, was the source of the trouble; and since it has been removed the family have recovered their usual health. The boiler had not been used for some time after the tap was put in, and when it was, the servant was warned not to use the water from it for cooking purposes. This order she appears to have obeyed only so far as her own food was concerned, hence her immunity from sickness.

Rupture of Aorta During Labor.

This case, which Heinricius reports in the *Archives de Tocologie*, January, 1884, is supposed to be without a parallel in medical literature. A woman aged 38, for the third time pregnant, and in whom the uterine contractions were energetic, was suddenly seized with a convulsion, became comatose, and died. The forceps were applied, and the child delivered. The autopsy showed that the pericardium was distended with a large quantity of blood. The heart was fatty, and strongly contracted. A little above the sigmoid valves was found a rupture of the aorta, involving the internal and middle coats. The aortic coat was very thin at the seat of rupture, and there was a small spot of atheroma on the ascending portion of the vessel. Heinricius thinks that the rupture was due to the increased blood-pressure caused by the energetic contractions of the uterus and the abdominal walls.

Another Argument for Vaccination.

Dr. Walter Buchanan thus writes to one of our English exchanges:

If nothing else could convince us as to the value of vaccination, I think the following facts would be sufficient:

In July last, I was called to see Mrs. B., who was suffering from small-pox. Her husband and three children were unvaccinated; the father and two eldest were vaccinated by me when the eruption on the mother was in the papular stage: the youngest being very delicate, and the parents being opposed to vaccination, I deemed it advisable not to operate on the child. The results were as follows:

1. The mother made a good recovery.
2. The unvaccinated child died from small-pox on the fourth day of the eruption.
3. Those who were vaccinated escaped from infection entirely.

Chestnut Leaves in Whooping-cough.

Dr. J. Coopreider, of Taylorsville, Ind., writes to the *Canada Med. Record* that he has used the fluid extract of chestnut leaves for whooping-cough, with great success. He says:

The dose employed is from fifteen to sixty drops, according to age. If the child is large enough, I give it in hot water as an infusion, sweetened; to a small child, in simple syrup or elixir.

It not only relieves or lightens the paroxysms, but will actually cure in from four to five days.

I give four to six doses per day, according to the severity of the case.

If good fresh leaves can be procured, I make the infusion as a tea, say two drachms of the leaves to half a pint of boiling water, and give two ounces at a dose, sweetened with white sugar.

Jaborandi in Bright's Disease.

Both reason and experience do most clearly indicate the beneficial influence of jaborandi in Bright's disease. We are, therefore, pleased to note in the *Med. Record*, March 22, 1884, a communication from Dr. F. A. O'Brien, of Atlanta, Ga., in which he calls attention to the beneficial action of jaborandi, given in small or moderate doses, for a long time, in the various forms of albuminuria classed under the head of Bright's disease. He has found that the drug is better borne when combined with nux vomica than if exhibited alone. In his opinion the action of jaborandi is not to be explained solely from its sialogogue and diaphoretic effects. He believes that it has a specific influence on the kidneys, permitting the tubules to relieve themselves of the inflammatory products that block up their lumina.

An Insecticide for Fruit Trees.

From the *Chemist and Druggist* we learn that Mr. R. McClachlan, F. R. S., reporting on an insect attacking the orange-trees in British Guiana, says:

"The most effective of all insecticides is termed 'kerosene emulsion,' the formula for the preparation of which is here given:

Pure kerosene,	1 gallon.
Condensed milk,	1½ pints.
Water,	3 pints.

Mix the milk and the water before adding the oil, and churn until the whole solidifies and forms a 'butter.' In applying this preparation, the kerosene 'butter' should be diluted with from twelve to sixteen times its quantity of water, and then

be applied immediately; for if it is allowed to stand, the 'butter' rises to the surface, and the solution is imperfect. The insects can be more readily combated by insecticides during the very short period in which they are active, just after emergence from the egg."

Kerosene Poisoning.

In the *Druggist's Circular and Chem. Gaz.*, February, 1884, Dr. C. S. Wheeler, of Williamsburg, Mass., reports the history of a case of kerosene poisoning, which is instructive, as these accidents are rare. He says: "I was called October 29th to see a child, eighteen months old, who had swallowed an unknown quantity of kerosene, though the amount did not probably exceed two ounces. The little patient, seen one hour subsequently to the swallowing, was vomiting, purging, cyanotic; a tendency to coma existed, the pulse was 130, weak, and somewhat irregular; respiration was also irregular. Treatment: ordinary emetics were given before my arrival, hence only stimulants and alkalies were ordered. After a few days of gastro-enteric febrile movement, the child recovered. I have heard of several ounces of kerosene having been taken by adults without perceptible results, but the above case compels me to doubt the statement."

Congenital Femoral Hernia.

Dr. Sabourin has recorded, in the *Progrès Médical* (January 26), the case of a female child, born at seven months, and small but well developed, in whom the mother, a few days after birth, noticed a swelling in the right inguinal region. Six weeks later, when Dr. Sabourin was called in, the tumor had attained the size of a filbert; it was situated in the upper part of the right thigh, below Poupart's ligament, and on the inner side of the femoral artery. It disappeared on pressure with a distinct gurgling sensation, and reappeared when the child cried. After reduction, the borders of an opening in the fascia could be felt. The hernia was cured in less than three months by the pressure of a small pad.

Liebig's Infants' Soup.

According to Meffdorsky (*Pharm. Zeitsch. J. Russ.*), quoted in the *Rundschau*, this food can be thus prepared: Take 480 parts of freshly-ground wheat flour, not the finest; 480 parts of ground malt; 15 parts of bicarbonate soda; mix with 960 parts of water, and 4,800 of milk. Stir well

over a gentle fire till the mixture begins to thicken. Then remove the mixture and stir well for five minutes. Heat again, and when it next begins to thicken, raise the heat till the mixture just begins to boil. Then pass through a fine strainer, so that the husks may be removed. The food is sweet enough without additional sugar. It will keep for 24 hours.

Tincture of Cantharides for Suppression of Urine.

This drug is not usually recommended in such cases, but in the *Boston Med. and Surg. Jour.*, March 22, 1884, Dr. W. C. B. Fifield reports a case, which he had seen in consultation with Dr. Rogers, of Dorchester. The patient was a hard drinker, whose symptoms were at first obscure, but who had later had albuminuria with casts. Complete suppression had lasted some days. Active treatment had been of no avail, and the patient was comatose and failing. Tincture of cantharides was then given hourly in drop doses, and after some hours the secretion was reëstablished, and the patient recovered so far as to be out.

Artificial Coumarin.

From the *Pharmaceutical Journal* we learn that coumarin is the odoriferous principle of the tonka bean, woodruff, sweet-smelling grass, and other plants, which owe their aroma and value exclusively to the coumarin they contain, the other principles being not only valueless, but disadvantageous. Coumarin has now been made artificially: one method of preparation is by warming sodium salicylaldehyde ($\text{NaC}_7\text{H}_5\text{O}_2$) with an anhydrous acid, or by boiling salicylaldehyde with sodium acetate and anhydrous acid. Recent improvements in the process have greatly shortened the time and expense.

Dislocation Forwards of the Four Inner Metacarpal Bones.

As a valuable contribution to surgery, it is of interest to note that this rare accident is described by Habillon, of Nancy, in his graduation thesis. He has collected thirteen cases, all men, and resulting either from direct violence or from extreme flexion or extension of the wrist. In his own case, the dislocation was caused by the passing of a wheel over the hand, and there was a wound on the dorsal aspect of the wrist. The reduction is easy, but difficult to maintain, and a certain degree of subluxation and stiffness is generally left.

CORRESPONDENCE.

A Plea for Venesection.

EDS. MED. AND SURG. REPORTER :—

Apropos to the remarks on the subject of blood-letting by Dr. Hiram Corson, I send you the following report of a case which, to me, seemed to present some interesting features:

About 3 p. m. on November 26, 1883, I was summoned hastily to see Mr. T. M., aged about sixty-five, whom I found presenting the following symptoms: Clonic convulsions, very severe, and occurring on an average about one per minute. Face very much flushed—nearly livid. There were some spasmodic efforts to reject the contents of the stomach. Breathing stertorous. The family informed me that about half an hour before, he had been sitting in a chair, and suddenly commenced to jerk his head backwards and over one shoulder, and in a moment or two fell to the floor in convulsions. I observed that the left arm and leg did not participate in the convulsive movements. I immediately diagnosed "apoplexy," and with difficulty, on account of the violent nature of the convulsions, got his coat off and his sleeve up, with a view to blood-letting. The blood did not start readily—a few drops only at first; after a little it came more freely, and I finally, by tapping a vein in each arm, succeeded in getting about a *quart*. There was no marked change in his condition, unless, perchance, the lividity of the face might have been slightly lessened.

At this point, my friend Dr. Hurlbut arrived. We consulted hastily as to the best means of averting death, which seemed imminent. The pulse, which was strong and full at the first and about 110 per minute, seemed possibly a trifle softer. We resolved to bleed until there was some marked impression made upon the convulsions. Both arms were ligated and new veins opened. The blood ran very slowly, while we watched the symptoms. We let the blood run until two *pint tins* had been filled, making an aggregate of over two *quarts*. The convulsions had now nearly ceased, the face had become pale, and the breathing less stertorous. There were still some twitchings of the muscles of the face and some spasmodic actions, confined to the right arm and leg, the left side being as from the first apparently paralyzed. I went to my office, a few rods only, for a hypodermic syringe, intending to inject a small quantity of morphia to quiet this muscular twitching; but when I returned a few moments afterwards, the spasmodic action had entirely ceased, and the morphia was not used. About three hours later we saw our patient, and found that there were some signs of returning consciousness. At this point there was an interesting feature of the case which we are unable to account for, viz., the paralysis, which had been so well marked on the *left* side had been transferred to the *right* side, and the *left* side he now seemed to move with ease. The convulsions did not return. He passed a reasonably good night. In the morning consciousness had so nearly returned that he was able to answer questions put to him, though not always rationally. The paralysis had entirely

disappeared save as regards the tongue, which seemed a trifle thick. From this time on he made a good recovery, and has been apparently in better health than before the attack. The particularly marked feature about this case was the unusually large quantity of blood taken. In our opinion no less amount of blood taken, and no other kind of treatment, would have saved him. The measured quantity of blood was not the only amount of blood lost, for a considerable quantity was lost in our endeavors to hold the arms over the receptacles for the blood, the spasmodic actions greatly hindering our efforts. Now, the question arises, Is there any limit to the amount of blood which should be taken in such cases? Our patient was of plethoric habit, and could therefore endure a greater loss than some. We think the rule should be: Bleed until you get the desired effect. Query: Why did the paralysis alternate from one side to the other? and could the patient have been saved by any treatment less heroic?

WALTER H. PARCELS, M. D.

Lewistown, Pa.

Running for Trains.

EDS. MED. AND SURG. REPORTER:—

In your last issue was a short article as a caution against the very pernicious practice of running to catch trains. Had I read and heeded this advice, something over a year ago, I perhaps should not be so ready to see the importance of riveting this knowledge of caution on the minds of physicians, and through them to the public and business men of our country. But my personal experience on this subject leads me to see that no one subject demands more attention than this; and perhaps no advice a physician could give would be more kindly received, or be better heeded, than advice on the subject we are interested in, viz., running for trains. And if the advice of physicians be, lose a train, or a dozen of them, rather than put future health or present life in jeopardy, and if this advice be well heeded, it no doubt would save many a valuable life among our great ones. My own experience in running to catch trains is this: Something over one year ago I was called to see a patient several miles from home, and consequently took the train. Only having a short time to visit my patient in, and walk about eighty rods from the depot, I made as good time as possible to get where my patient was; but owing to circumstances connected with the patient, I could not get started for the depot until almost the time that the train was due at the depot. I had only just started from the house, when I saw the train coming. Had I used a little judgment I should not have made the attempt to get to the train. But I thought I might make it, so I started on a fast run, which I kept up to the depot, and just as I reached the depot the train departed, and I, being too much exhausted to make any extra effort to reach the train, was left behind to feel ashamed that I had shown so little judgment, and worse than all, to find that I could not breathe naturally for the rest of that day. I could with difficulty get sufficient air to keep up the demand to sustain life; following this was a constant pain near or in the region of the heart, with a remitting pulse. After three or four months the pulse

regained its regular beat, but a feeble, weak pulse remains with me; also, a dull, heavy pain, which is made worse by anything which excites the circulation. Stimulants I do not use, so cannot say how they would affect me—not even tea or coffee.

I have consulted some good physicians; have tried blistering and tincture of iodine to surface over the heart, but all the effect I see from this was to excite a few small-sized carbuncles; so am now wearing a good, strong irritating plaster over the cardiac region, on the scapular side. This, apparently, is doing good, as it relieves the pain, and is, in my mind, indirectly giving strength to the feeble action of the heart. Nux vomica was recommended by one. This not only seemed to do no good, but I thought actually made the pulse more intermittent, and increased the pain; so I stopped its use and commenced taking small doses of quinine, iron, and strychnia. This appeared to regulate the pulse, after which I stopped its use. Have not taken anything now for eight or ten months; am doing well with my plaster, and all the rest I can get. J. D. APPELEY, M. D.

Blodgett Mills, N. Y., March 16, 1884.

Chronic Nasal Hemorrhage.

EDS. MED. AND SURG. REPORTER:

Please oblige the writer by requesting those of your readers whose experience may enable them to speak, through the department of "Queries and Replies," in the REPORTER, with regard to the best curative treatment for *chronic nasal hemorrhage*. We refer to the case of a boy (white), now about ten years of age, who, we learn from his mother, has been subject to frequent spells of bleeding from the nose, every few days since early infancy. Sometimes the bleeding is very profuse and exhausting; at other times it is slight, merely issuing drop by drop.

The patient has only been under our notice during the past year; and we have never seen him with a serious hemorrhage, and hence have never been compelled to resort to any active measures for his relief. Neither have we been able to make any thorough examination of the interior nares, because, at the time of our visits, the bleeding surface was covered with clotted blood, and the discharge almost arrested by the local use of such astringents as alum water, and more especially by a strong solution of ammonio-ferric alum—introduced by means of pledgets of cotton. The tincture of the chloride of iron has also been freely used, internally, as an astringent tonic. The attacks are not often so violent as to cause alarm, but the trouble is in a constant tendency to the return of the bleeding; and it reappears without any known exciting cause. It frequently occurs during sleep. Its return is often foreshadowed by *headache*. It is extremely rare for him to pass two weeks without some bleeding; and it sometimes continues slightly two or three days in succession. The boy always presents an *anemic* appearance, but has a good appetite, and is otherwise healthy. He goes to school, but frequently has to go home during the day, on account of the bleeding. And he also joins in the amusements and plays of other children of his age.

The first question we ask is, "What means can be adopted to bring about a radical cure of this

hemorrhagic diathesis?" The second is, "Would not some evil results, in all probability, follow such a cure?" Finally, "What is the best course to be pursued in this case?"

We have never examined the condition of the nasal membrane, for want of an opportunity, as before stated. The boy has, habitually, a "nasal tone" in conversation, and the bleeding is invariably from the right nostril.

We would be pleased to have information from any who have had experience with a similar case.

W. S. F., of Md.

March 10, 1884.

Eczema Scrofulosa.

EDS. MED. AND SURG. REPORTER:—

J. H. A. K., æt. 50, came into the Pittsburgh Infirmary for treatment February 27, 1884, suffering with eczema scrofulosa. He had been a sufferer with this disease since the middle of September, 1883. The dermis on the front and internal surface of the right thigh was quite denuded of its epidermis, red, and unbearably itchy; on the left thigh there were vesicles, and the parts very red and itchy. The disease affected the genital organs and anus, and in fact extended all over the body. The patient's father died of cancer at the age of 53 years. Paternal and maternal grandparents lived till between the ages of 60 and 70 years. There was no history of disease in them of a specific character. The subject of this paper suffered with periostitis and osteitis when he was 14 years old, and lost the fibula and os calcis of the left leg and foot from these diseases. The left elbow-joint was also affected, and now there is ankylosis of it. At the present time there is a fistulous opening leading to the posterior part of the femur, just above the knee-joint, through which necrosed bone can be felt. The patient has been treated by several physicians since last September for eczema, without any relief. Drs. M. D. Jones and A. Lange saw the case with me when he first came into the hospital. At this date he is almost recovered from eczema.

Treatment, internally, 15 grains of iodide of potassium three times a day, after eating, generous diet, hot bran bath once a day, and unguent of the oxide of zinc smeared over the affected parts three or four times a day.

I believe, with a great majority of physicians of the present day, that scrofula, cancer, and in many cases phthisis pulmonalis, have their origin in syphilis, and require the same constitutional treatment, and that the subject of this paper is a victim to transmitted syphilis.

J. M. BATTEN, M. D.

Pittsburgh, March 15, 1884.

Heredity.

EDS. MED. AND SURG. REPORTER:—

In your remarks on Heredity, page 179, vol. I, No. 6, you "lean" to the proposition that all diseases resulting in change of form or function may be transmitted. If accidentally acquired change of form may not also be transmitted, how will you account for the following cases?

In 1857 Mrs. W. died of phthisis, leaving three

daughters and one son. Her genital region was very badly scarred from a burn received before puberty, and she stated that after recovery she underwent an operation for occlusion of the vagina. The oldest daughter had but one child, a boy. The second daughter had but one child, a girl, which had congenital closure of the vagina. The third daughter has, so far, had but three children—the two boys being all right, but the girl required an operation for congenital occlusion of the vagina. I have lost track of the boy, but hope soon to get on his trail, and keep it till he also raises a family.

F. R. MILLARD, M. D.

San Diego, Cal.

NEWS AND MISCELLANY.

Correction.

In No. 9, p. 263, cur. vol., a rather ridiculous error occurred by the accidental omission of the word "apparently" before "still-born child." One or two friends have called attention to it, so we make this note.

Jefferson Medical College.

The fifty-ninth annual commencement of the Jefferson Medical College was held in the Academy of Music on Saturday, March 29, 1884. The degree of M. D. was conferred upon two hundred and fifteen students, and the following prizes were awarded:

1. \$100, by Henry C. Lea's Son & Co., for the best thesis, to John A. Buffington, of Maryland; with honorable mention of the theses of W. H. Vallette, of Ohio, and S. B. Horning, of Pennsylvania.

2. Gold medal, by R. J. Levis, M. D., for the best report of his surgical clinics at the Pennsylvania Hospital, to Thomas C. Hood, of Indiana.

3. Gold medal, by Thomas G. Morton, M. D., for the best report of his surgical clinics at the Pennsylvania Hospital, to Frederick Hertel, of Delaware; with honorable mention of the reports of Andrew B. Kirkpatrick, of Philadelphia, and Thomas Roby, of Missouri.

4. Gold medal, for the best essay on the subject pertaining to the practice of medicine, to James H. Bell, of Texas; with honorable mention of the thesis of B. W. MacNichol, of New York.

5. Gold medal, for the best original research in the chemical laboratory, to Sidney A. Stokes, of Pennsylvania; with honorable mention of the essay of Irving R. Schoonmaker, of Pennsylvania.

6. Case of instruments, for the best original research in the materia medica laboratory, to J. Edwin Sprenkle, of Philadelphia.

7. Case of instruments, for the best essay on a subject pertaining to physiology, to David A. Kappes, of Ohio; with honorable mention of the essay of William F. Kuhn, of Ohio.

8. Case of instruments for the best essay on a subject pertaining to surgery, to William A. Vaughan, of Virginia; with honorable mention of the thesis of A. J. Comstock, Jr., of California.

9. Gold medal for an essay on a subject pertaining to obstetrics, to Levi Huber, of Pennsyl-

vania, and another of equal value to L. M. Nason, of Maine; with honorable mention of the essays of John W. Felty, Justus Sinexson, and Evan O. Kane, of Pennsylvania.

10. Gold medal, for the best essay on a pathological subject, to William H. Fenner, of Pennsylvania; with honorable mention of the essays of Edward F. Wagner and John M. Fisher, of Pennsylvania.

The valedictory address was delivered by John H. Brinton, M. D., Professor of the Practice of Surgery and Clinical Surgery. In pointing out to the newly-made doctors the pathway to professional success, Dr. Brinton said that if they expected to become rich men, they would in all probability be disappointed. Few medical men, by the practice of their profession, ever amassed wealth; but they could always, by diligence and devotion to it, attain a decent competency. With this, and with the daily healthful exertion necessary to ensure it; came, he thought, as great a degree of happiness as any man can reasonably hope for. A successful physician must have a sound medical knowledge; but although nominally the graduates ceased to be students, in reality their student life had but begun. He advised them to keep note of their cases, so that in turn they could be able to contribute something to the general stock of medical learning. They should not, however, rush carelessly into print, but write because they have something to say, not because they wished to say something. They should always seek to preserve their individuality, and not be carried away by theory nor by plausible or fallacious reasoning. Dr. Brinton advised the graduates when they had gotten fairly to work, to join a good medical society, which would prevent them from becoming rusty; to keep up an interest in their calling, and take care of their business; to work steadily and work in a right manner and a proper spirit, and with honesty and a conscientious purpose. The physician should be a gentleman, not only in outward demeanor, but in very heart, and should most carefully refrain from impressions of ill-will towards his brethren, or adverse criticisms of their actions. Dr. Brinton impressed upon his hearers the great duty they owed the science of medicine in the solution of the problem of many diseases which still baffle medical treatment, such as consumption, diphtheria, the wave of pestilence, wide-spreading cholera, and fevers, deadly as were the plagues of Egypt, and those poisons of the blood, cancer, scrofula, and all their kin. In concluding, Dr. Brinton said:

"The history of the past often points with prophetic finger, to the future. One man, great Jenner, barred the spread of small-pox, and other maladies may yet be checked by men whose names will then be blessed not less than his. When the times are ripe these men are born. I need not wander far to find a scarce-closed grave of such a one; one of your predecessors, a child of our own Alma Mater, who by his life and teachings, and by the unspeakable benefits he has conferred upon suffering womankind, deserves unquestionably to be regarded as one of the great benefactors of his race. Well may the profession throughout this land join hands to raise a monumental tablet commemorative of the loveliness of the character,

the goodness of the works, and the undying fame, of Marion Sims."

Pasteur's Laboratory.

M. Pasteur's son-in-law has written a work descriptive of the great man's scientific life, entitled "*L' Histoire d' un Savant par un Ignorant*," from which we quote the following:

"All the animals in the laboratory, from the little white mice hiding under a bundle of cotton wool to the dogs barking furiously from behind their iron-railed kennels, are doomed to death. These inhabitants of the laboratory, which are marched out day after day in order to be subjected to operations or other experiments, share the space with still more ghastly objects. From all parts of France hampers arrive containing fowls which have died of cholera or some other disease. Here is an enormous basket bound with straw; it contains the body of a pig which has died of fever. A fragment of lung, forwarded in a tin box, is from a cow dying of pneumonia. Other goods are still more precious. Since M. Pasteur, two years ago, went to Pauillac to await the arrival of a boat which brought yellow fever patients, he receives now and then from far-off countries a bottle of *vomito negro*. Tubes filled with blood are lying about, and small plates containing drops of blood may be seen everywhere on the work-tables. In special stores bottle-like bladders are ranged resembling small liquor bottles. The prick of a pin into one of these bladders would bring death to any man. Inclosed in glass prisons millions and millions of microbes live and multiply."

The Scavenging of Paris.

Hitherto the system of scavenging in Paris has been imperfectly carried out. The refuse matter of each house used to be deposited in the street after 10 o'clock at night, where it lay till the next morning, when it was carted off by scavengers. This was found to be a great nuisance; and a new order from the Prefecture of Police has just been published, altering this state of things. The refuse matter is to be deposited in receptacles for the purpose early in the morning only, and is to be immediately removed by the municipal scavengers. Any infringement of this regulation by the proprietors or porters of houses, who will be held responsible, will be severely punished. But this new arrangement does not meet with the satisfaction of the "*chiffonniers*," who have petitioned the Prefect of Police to allow matters to remain as before, as the new regulations would be simply ruinous to them. The fact is, rag-gathering would appear to be not an altogether unprofitable calling, as cases are related where some of these people have actually died in comparative wealth. Not long ago a "*chiffonnier*," at his death, was found to possess \$20,000, and yet he lived in the most abject misery.

Jefferson Medical College Alumni.

The Alumni Association of Jefferson Medical College held their fourteenth annual meeting at the college, March 28, and elected the following officers:

President.—Professor S. D. Gross.

Vice Presidents.—Drs. A. Hewson, Ellwood Wilson, R. J. Levis, Roberts Bartholow.

Treasurer.—Dr. Nathan Hatfield.

Secretaries.—Drs. T. H. Andrews and R. J. Dunglison.

The deaths of Dr. J. Marion Sims, an alumnus of the college, and Dr. R. T. Coleman, an honorary Vice President of the Association, were appropriately referred to in the report of the Executive Committee, and a continuance of the social meetings of the graduates was recommended. Dr. Theophilus Parvin, the new Professor of Obstetrics in the College, was elected an honorary member of the Association; and Dr. J. W. Holland, of the University of Louisville, Ky., was chosen to give the address next year.

The Treatment of Syphilis.

Bichromate of potass as an antisymphilitic has for partisan in Saxony Dr. Güntz, and in France Prof. Vulpian. The former employs it in solution charged with carbonic gas, as follows :

R. Bichromate of potass,	$\frac{2}{3}$ gr.
Nitrate of potass,	2 gr.
Nitrate of soda,	2 gr.
Chloride of sodium,	4 gr.
Water charged with gas,	$\frac{3}{8}$ xx.

M. Vulpian also recommends it in dyspepsia depending on a catarrhal affection of the stomach simulating carcinoma of that organ. He prefers it in the form of pills :

R. Bichromate of potass,	1 gr.
Extract of valerian,	10 gr.

Divide into 5 pills. One, two, or three in the day.

It will be remembered that it was Prof. Vulpian who attended the late Count de Chambord, and having recognized that disease as catarrh of the stomach, prescribed these pills, but, it must be added, with little result.

Legality of Cremation.

It has been decided by the English courts that cremation is a legal method of disposing of corpses. The Cremation Society, however, have prudently adopted the following rules :

1. An application in writing must be made by the friends or executors of the deceased—unless it has been made by the deceased person himself during life—stating that it was the wish of the deceased to be cremated after death.

2. A certificate must be sent in by one qualified medical man at least, who attended the deceased until the time of death, unhesitatingly stating that the cause of death was natural, and what that cause was.

3. If no medical man attended during the illness, an autopsy must be made by a medical officer appointed by the Society, or no cremation can take place.

Fascination.

From the *Brit. Med. Jour.*, we learn that M. Brémond has made, on sailors, soldiers, and officers, from fourteen to twenty-six years of age, a large number of experiments showing that lethargy, catalepsy, and somnambulism, can be pro-

duced in healthy non-hysterical people, and that these phenomena are preceded by a peculiar state of fascination. The period of fascination is characterized by a sudden increase in the frequency of the pulse. One-third of the young men experimented upon manifested one or more of the above-mentioned symptoms.

Delusions and Executive Ability.

The *Birmingham Medical Review* reports that one of the members of the Executive Council of the Bank of Brussels was many years ago attacked by the delusion that his legs were glass, and positively refused to move. A financial crisis came, involving the bank to some extent. Mr. B. got up and went to Brussels, where, by his energy and skill, he largely assisted in getting matters straight. At the end of the month he returned home, remarked how marvelous it was that he had not smashed even one of his legs, and, taking to bed, never again left it.

The Origin of the Hymen.

Dr. Pozzi, of Paris, in a recent paper defended the opinion that this membrane depends from the vulva and not the vagina, as was the opinion of Budin. Further, he considered that that portion of the genital organs commonly called the bulb of the vagina as the analogy of the urethral bulb in man, was nothing more than a rich plexus of vessels.

The Mortality Caused by One German Hog.

In a dispatch from Berlin, dated March 27, 1884, it is officially stated that last year at Ermsleben, a small town of Prussian-Saxony, 403 persons were seriously ill and 66 died from trichinosis. The disease was caused by eating raw pork, which all came from one and the same hog.

Items.

—It is stated that the foot-ball eleven of a prominent college started on its late contest with eight substitutes and a surgeon.

—The Indiana State medical Society meeting has been postponed until after the meeting of the American Medical Association.

—A bill has been introduced into the House of Commons providing for the restriction of the sale of patented medicines until they have been officially analyzed and pronounced not poisonous.

—The New York Assembly has passed a bill limiting the time of service of conductors and drivers on city railways to twelve hours a day. In Philadelphia these men work from sixteen to eighteen hours a day.

—The fifth International Congress of Hygiene will meet at the Hague, August 21 to 27, 1884. The papers to be read will consider individual and general hygiene, sanitary police, demography, and medical statistics.

—The twenty-third annual commencement of Bellevue Medical College, New York, was held in Steinway Hall on Thursday evening, March 13. The degree of M. D. was conferred upon one hundred and forty-nine graduates.

—Another coroner's verdict. It was rendered at Pekin, Ill., on the body of a man found in the river, and declared "that the late deceased had come to his death by a blow on the head inflicted either before or after he was drowned."

—James Russell Lowell writes to a friend in Boston that he likes living in London "all but the living." He is becoming dyspeptic, and attributes it to his entire and enforced abstinence from fresh and salt cod, clams, buckwheat cakes, and baked beans, which are actual necessities almost wholly unknown in Great Britain.

—The new buildings of the Medical Department, University of Vermont, erected by John P. Howard, at a cost of \$30,000, was dedicated March 6. The building was presented to the University in behalf of Mr. Howard by Henry Ballard, and was accepted in an address by President Buckingham. The medical class numbers 200 students.

—The Maryland House Committee on Ways and Means has reported favorably Mr. Lane's High License bill, which has already passed the Senate. For selling liquor in quantities not less than a pint, the prices of license range from \$50 on \$1,000 worth of stock, to over \$300 on \$30,000 in stock; for selling quantities less than a pint, from \$150 to \$500, according to population.

—The question of the regeneration of divided nerves in man after suture has been the subject of fresh discussion at recent meetings of the Société de Chirurgie (*L'Union Médicale*, December 4). Mr. Pick has recorded a case of suture of the radial nerve six months after its complete division, with the result of functional restoration after a period of twelve months from the operation.

QUERIES AND REPLIES.

EDS. MED. AND SURG. REP.—

Please give me the result of your experience in the use of plaster of Paris dressing in the treatment of club-foot. If you have found it satisfactory, will you be kind enough to write me, giving minutely your method of application? That is to say, after the tendons have been divided, do you apply the plaster at once, as in the case of fracture; and, if so, how long would you allow it to remain before removing it? how frequently would it be necessary, say in an infant less than one year old, to change the dressing? and how long, generally, should the child wear the plaster dressing before it would be safe to dispense with it? Can the cure be brought about with the plaster dressing alone, or would it be better, after a time, to apply the ordinary club-foot apparatus? I am told that the practice of treatment by the use of plaster of Paris is becoming quite prevalent, and as I am so thoroughly "behind the light-house" on this subject, I ask for information. Any paper which you may have at hand, relating to the case in point, will be thankfully received.

Mansfield, O.

W. H. R.

A Formula for Salicylic Acid.

EDS. MED. AND SURG. REP.—

Will you please give me, through your journal, a formula for the administration of *acid salicylic* which will effect a *thorough solution of the acid*, and at the same time in no sense detract from its medicinal qualities? Does the exhibition of alkalies used by druggists to effect this solution destroy the action of the salicylic as an acid, or injure its chemical or medicinal qualities in any sense? E. S. B.

D. M. P., of Pa.—Labarraque's solution is the *liquor sodæ chlorinate*.

Dr. B., of Pa.—We have been unable to learn of any observations connecting the presence or the absence of the uvula with fertility.

Dr. V. O., of Ky.—The statement that persons in the Arctic regions are little subject to lung disease is an error. Dr. H. Hink states that in Greenland thirty-five per cent. of the deaths are from pulmonary affections.

Dr. A. K., of Md.—The mineral waters of the United States have never been thoroughly examined. We believe that there are many springs here equal to the best in Europe.

MARRIAGES.

BARNES—PENN.—At the residence of Rev. Bristow, No. 15 West Ninth street, Covington, Ky., Dr. T. S. Barnes, of Pike county, and Miss Mollie Penn, of Clermont county, Ohio.

FRENCH—WOOD.—At the residence of her relatives, Mr. and Mrs. Gayle, Newport, Ky., March 5, 1884, by the Rev. S. L. Loomis, Dr. M. R. French, of Cincinnati, and Miss Sarah B. Wood. No cards.

LEMEN—CHICK.—At the residence of the bride's parents, 3214 Morgan street, St. Louis, March 12, 1884, Dr. J. R. Lemen and Miss Ida May Chick.

MURPHY—THOMAS.—In Parkesburgh, Pa., March 13, 1884, by the Rev. James A. Marshall, Walter A. Murphy, M. D., and Sallie K. Thomas.

REEDER—WELLS.—At Spring Lake, Ohio, February 20, 1884, by Rev. H. H. Wells, D. D., the bride's brother, Charles W. Reeder, M. D., of Wickliffe, O., and Emma C. Wells, of Willoughby, O.

ROGERS—CHALMERS.—At the residence of the bride's father, General J. R. Chalmers, near Sardis, Miss., February 21, 1884, Dr. W. B. Rogers, of Memphis, and Miss Kate H. Chalmers.

WORMLEY—MADSEN.—In this city, February 17, 1884, by the Rev. Dr. H. C. McCook, Dr. William Wormley, of Lancaster, Pa., and Emilie Madsen, of Philadelphia.

DEATHS.

DU BOSE.—At Sunflower Landing, Tenn., February 20, 1884, of pneumonia, Dr. W. J. Du Bose.

DU BOSE.—At Sunflower Landing, Tenn., March 6, 1884, Myrtice M. Du Bose, wife of the late Dr. W. J. Du Bose.

ELWYN.—In this city, March 15, 1884, Alfred Langdon Elwyn, M. D., in the eightieth year of his age.

FISHER.—In St. Louis, March 10, 1884, Dr. Gustavus Fisher, aged seventy-two years.

HURDSFIELD.—At his late residence, 261 West Thirty, eighth street, New York city, Monday, March 3, 1884, John Hursfield, M. D., in the fortieth year of his age.

KEITH.—At Jacksonville, Florida, Thursday, March 13, 1884, Dr. Bethuel Keith, formerly of this city and Stamford, Conn.

MCDONNELL.—At his late residence, 148 East Forty-fourth street, New York city, Saturday, March 8, 1884, after a lingering illness, Dr. P. W. McDonnell, Police Surgeon.

MERCER.—In Jeffersonville, Ind., February 28, 1884, of paralysis, Dr. Thos. C. Mercer, a native of Louisville, Ky., aged sixty-four years.

WILLARD.—In Haddonfield, N. J., March 10, 1884, Roland Willard, M. D., in the ninetieth year of his age.

WOOD.—At his late residence, in Flushing, N. Y., March 7, 1884, Stephen Wood, M. D., aged seventy-three years.

MORRIS.—In this city, March 17, 1884, Caspar Morris, M. D., in the seventy-ninth year of his age.

PULTE.—In Cincinnati, Ohio, Sunday, February 24, 1884, at 4 a. m., of general debility, Dr. Joseph H. Pulte, in the seventy-third year of his age.

STILLMAN.—In Troy, N. Y., March 21, 1884, Dr. A. G. Stillman. He was a pupil of President Arthur in the District School at Pownall, Vt.

DOUGLASS.—March 13, 1884, Dr. J. H. Douglass, aged seventy-five years.

MILK SICKNESS.

BY THE LATE DR. FULTON.

Read before the Logan County (Ohio) Medical Society.

Notwithstanding the great diversity of opinion in reference to the *cause* of this peculiar disease—no vegetable or mineral having yet been unmistakably identified as the guilty agent—yet all agree, with united voice, that it is a specific poison, producing a disease *per se*. And the agreement is as unanimous that it is *endemic*. And, although there are frequently cases of the poisoning, and even deaths, far from these localities, which the physicians, where they occur, do not understand, or know what to call, or how to treat; yet the poison was obtained in those localities, and transferred to its place of destination in meat, butter, or cheese, and there received into the system and produced its results.

But as to whether the specific virus is of vegetable or mineral origin, there is no agreement—each having about an equal number of adherents; and each, generally, being founded in his belief, either from preconceived opinion of his own, or the accidental opinion of the neighbors, positively and perseveringly asserted, without his taking the trouble to inquire into and investigate all the ascertainable facts connected with the case.

The vegetable theorists, whether in favor of white snake-root, lobelia, poison-oak, or what not, do not claim, excepting some of the most reckless observers and asserters, that they have seen the disease produced, in either man or beast, by the administration, or voluntary use, of their favorite

article. That there have been instances of poisoning by all these articles, and also by the buckeye, and other vegetables, there is no doubt; and that, too, with many of the symptoms of milk sickness, but, that the *tout ensemble* of symptoms necessarily and invariably accompanying it, and which, taken together, unmistakably characterize the disease, is caused by them, is by the mineral theorists, positively denied.

On the other hand, neither do the mineralists claim that they have, or can produce, the disease by administering any of the minerals that they hold to be the guilty agents. But they do claim, that they have many satisfactory instances of cattle, and persons also, taking it from water, whatever article that water may have been impregnated with. As, for instance, the case given by Dr. White, in the *Transylvania Journal of Medicine*, January, 1836: "A respectable farmer informed me that his cattle had been in the habit of frequenting a pasture ground in company with his neighbor's, on the opposite side of the creek from him. In returning home, his cattle were obliged to cross the creek. For many years not a case of the disease appeared among them, while his neighbor lost some forty or fifty during that time. The animals of the latter did not cross the creek, but drank at another stream. Both herds ranged the same woods and fed on the same herbage. It is presumable, therefore, that the disorder was produced by the water; and, in confirmation of this opinion, this individual further stated to me that, suspecting a spring at which his cattle drank to be the origin of the evil, he set to work felling trees around it, so as to exclude his stock from it, and that afterward they suf-

fered no more with the disease for several years. At length, however, it recurred again, and on examination, it was found that the spring had become accessible from the decay of the timber. The inclosure being repaired, and the cattle shut out from the water, the disease a second time disappeared."

And many similar instances could be cited, some two or three of which have fallen under my own observation. One in Richland township, Logan county, O., where the cattle had been taking the disease from the first settlement of the country, and several persons on that and adjoining farms had taken it, and most of them had died, until a spring was finally suspected and enclosed—since which time to the present, some fifteen years, there has been no more of it.

Another, that of a low, marshy piece of ground in Brunswick township, of the same county, the country around which was notorious for the number of cattle that died of the disease, and of persons that took it, until, with the improved agriculture of the country, that place, with other low lands, was ditched and drained; since which time there has been no more of the disease in that neighborhood in either man or beast.

Another instance, that of a stock-well on a farm in Clark county, as I am informed by several credible witnesses, from which the cattle were accustomed to be watered, and had been taking the disease for a number of years, when it was suspected and closed, since which there has been no more of it.

Again, there is a farm in Hardin county, on which members of every family that has ever lived there have had the disease. On that farm I have attended patients who said that they had not used meat, milk, butter, or cheese for weeks, guarding against the disease. The presumption therefore was that they, and also those of the previous families that had lived there, had obtained it directly from the water.

And thus I might enumerate many more similar instances upon which the mineral theorists found their belief, without naming any article, either elementary or compound, believing it to be a thing yet to be discovered.

These facts militate equally against the zymotic or malarial theory.

Inception: Invasion.—The *stadium prodromorum*, or period intervening between the first impression of the morbid cause or the reception of the virus, and the actual outbreak of the more violent phenomena of the disease, varies greatly in length, from one day to weeks, or even months, depending

upon the amount of poison received, the susceptibility of the person receiving it, the toxic property of the virus, and habits or occupation of the recipient. If the person is of sedentary habits, not engaged in any occupation that requires much muscular activity to excite the heart or heat the system, he may receive and have a large amount of the poison lie dormant in his system for a long time without any visible signs of its presence. But let him labor hard, or take any violent exercise, till he heats himself, and the pathognomonic phenomena of the disease will immediately show themselves with terrific violence, the most notable of which are, overwhelming sickness of the stomach, with violent vomiting, and obstinate constipation of the bowels.

Every physician, or other person conversant with the disease, is perfectly familiar with the fact that the poison may lie dormant in the system in sufficient quantity, when the proper condition presents, to explode with terrific violence, without showing any signs of its presence till it is, so to speak, ignited by active exercise, or heating of the person. For instance, where persons, as is frequently the case, receive the poison in a poison district, and afterwards go into a neighborhood where the disease has never been known to have been, and upon being heated by hard labor, are taken down with the disease, the physician is called a fool, and perhaps turned off, for naming it "Milk Sickness;" "for," say they, "we don't have that disease here." Or, as is more frequently the case where cattle are bought in a poison district, *apparently* all right and healthy, but upon being run in driving them home, immediately take the "trembles," and, perhaps, are never gotten home, or, as is very generally the case, where the sucking calf takes the disease, while the mother, in whose system the poison was, shows no signs of the disease. Or, again, as in the case recorded by Dr. F. H. Sale, of Indiana: "A young calf took the 'trembles' and died. The cow was milked and the milk fed to two pigs that were in a pen. The pigs thrived and fattened, and in due time were slaughtered. The first meal that the man and his wife (owners of the pigs) took made them sick, and they both died in four days after eating the pork, with all the symptoms of Milk Sickness. *Neither cow nor pigs showed any signs of the disease.*"

Symptoms.—The group of invariable accompanying symptoms, which, in common language, constitutes the disease, do not, in the main, differ from those of the febrile diseases. But there are

some that are truly *diagnostic*, and so marked that there need not be any danger of mistaking it for any other disease.

The general symptoms are: derangement of the nervous system, producing mental and muscular languor; general *malaise*, and uncomfortable sensations, confusion and weakness of the intellectual powers, tremors of the extremities, changed expression of the countenance, and nausea. And, in the active state, the most terrible sickness, described by those who have experienced both, as more heart-depressing, hopeless, and unendurable than that of sea-sickness. This sickness is partially relieved for a few minutes after vomiting. The vomiting recurs so frequently, so violently, and so unmitigatedly, that it is well nigh an impossibility to have medicine retained long enough to take effect. After continuing for a length of time, if not prevented by the use of alkalies, the dejections assume the coffee-ground appearance, like the *vomito*, or black vomit of yellow fever.

Another symptom of the disease most prominent to the eye of the common observer, is the state of perfect inactivity of the bowels, or obstinate constipation, which, if counteracted and continued to be counteracted, the disease is cured. This, as will be shown hereafter, we believe to be the cause of the vomiting, and symptomatic of the true pathological condition of the organism.

There is a peculiar *smell* connected with the disease, which is considered by most observers as pathognomonic. Dr. Dawson, of Green county, Ohio, in giving the prominent symptoms of the disease, says: "As a premonitory symptom, a peculiar and indescribable *fetor* from the lungs, is the most prominent; and so universally have I found it present, and to precede the disease, that in almost every instance where I have been brought in proximity to a person predisposed or attacked, I have been able to foretell its approach, and pronounce the character of the disease."

Dr. J. Newland Smith mentions a *peculiar odor of the breath* as a characteristic symptom of the disease.

Dr. B. S. Brown, of Bellefontaine, Ohio, says: "There is an odor, *per se*, attending the disease, as easily distinguishable as that of garlic." And this is the almost universal testimony of those acquainted with the disease, both professional and unprofessional.

The *great tolerance of cathartic medicines* is, also, a characteristic feature of the disease. Some other diseases and certain conditions will occasionally bear a great amount of cathartics. But

Milk Sickness invariably tolerates and requires, to one not acquainted with the disease, an almost incredible amount of cathartics. I have known patients to take and retain from fifty to seventy doses of physic in about twice that number of hours, each dose sufficiently large to purge a man under ordinary circumstances; and, also, during the same time, receive a great many large and active enemata, and yet not be very freely purged.

There is another peculiarity connected with the disease, which, to me, is diagnostic. I mean the *moan* of the patient. Yet I have not seen it named by any other person. To my ear it is a moan so peculiarly characteristic, that I think it as distinguishable as the cough of croup. There are other affections in which patients moan as much as they do in this. But there is a peculiar tone of woe-begoneness and despondency connected with the milk-sick moan, which gives feature or physiognomy to it, that is easily recognizable, after having once heard it. And yet I cannot describe it in words, so that one not acquainted with it would know it upon first sight. To be known it must be heard. I think that I can diagnose the disease upon hearing the moan, without seeing the patient.

The *decubitus* of the patient, especially after the case becomes bad, is peculiar—an indifferent stolidity of countenance, a drawing forward and down of the head and shoulders, so as to lie partially across the bed, with the head hanging over and the clothes drawn forward and up, so as to uncover the feet.

I will mention one other pathognomonic, or at least invariably accompanying symptom, viz: a *collapsed condition of the abdomen*. This is a necessary consequence of the pathological condition of the viscera, as will be shown further on. At least it is present in every genuine case of the disease, to a greater or less extent. In the majority of cases the caving in is so great, that the pulsation of the abdominal aorta can be seen or plainly felt, as low down as the pelvis. When the collapse is not so perfect, it will be found that it will take more cathartic medicine to relieve the patient, owing, perhaps, to the greater accumulation of fecal matter at the invasion of the disease.

I will recapitulate, that you may have a condensed or bird's-eye view of the symptoms peculiar to the disease: 1. Frequent, violent, and persistent vomiting; 2. Coffee-ground, or black vomit; 3. Obstinate constipation; 4. Peculiar odor of the breath; 5. Remarkable tolerance of cathartic medicine; 6. A peculiar woe-begone moan; 7. A collapsed abdomen. All which,

when taken together, constitute a physiognomy of disease, which is easily and unmistakably recognized after having once seen it.

Diagnosis.—The diagnosis of the disease, as I have before intimated, is not at all a difficult matter. Yet it is very difficult, if not impossible, to point out, in words, the precise difference between any one symptom in this and the same in any other disease. But, taken collectively in the same case, with their relative connections and bearings one upon another, and he must be poor in individualizing who cannot, without difficulty, recognize it. I have often been asked if I was *certain* that it was milk sickness—if it might not be something else. I have answered, that if it was *not* that, I did not know what it was. That I knew that it was not any other disease that I had ever seen or read of.

But, fortunately, the symptoms are so marked, and the indications to be fulfilled so plain, that, though one may be slow in *naming* the disease, yet he need not be at any loss in making a rational prescription.

Pathology.—And this leads me to speak of the pathology of the disease. The first morbid impression of the poison is undoubtedly upon the nervous system, as is manifested by the common premonitory symptoms, as enumerated above. But the special and specific action, as I believe, is upon the ganglionic system, the source of the organic functions, and of all animal life.

As the brain and its prolongations—the cord and nerves—are the fountain and viaducts of mentality and sensation, so are the ganglia and their ramifications the seat and avenues of life and procreation, controlling the secretions, nutrition, circulation, and the involuntary motions. If, therefore, the solar plexus and its system of ganglia should become oppressed or paralyzed by a specific poison, or by any other means, the symptoms we would expect *a priori* would be very similar to those of Milk Sickness. The involuntary peristaltic action of the intestines would cease, and constipation would be the necessary consequence, especially after the lacteals and lymphatics had taken up their liquid contents. And it would be *persistent* until that action would, partially at least, be restored. And that is just the milk-sick condition.

Again, the vital stimulus that causes the peristaltic motion being removed, the intestinal muscles in that respect would be paralyzed, and the spinal nerves, still having their function unimpaired, would cause them to contract and close the calibre of the bowel. And that contraction

and closure would continue so long as the ganglionic stimulus was withheld. And here again is the precise milk-sick condition. In autopsies made by myself, on animals killed for that purpose, that had the disease, I found the small intestines contracted so close that they appeared like a large lumbricus their whole length. And I suppose that the large ones would have been in the same state, but that they were impacted with dry feces, so that they could not contract.

I find that this corresponds very nearly with a report of the examination of a body, dead from Milk Sickness, made by Dr. J. V. Wagman, of New Castle, Indiana. He says: "The brain and its membranes exhibited nothing remarkable; the kidneys, bladder, heart, and lungs were sound; the duodenum, as well as the lower part of the stomach, was *much contracted*; the cæcum was dry; and the colon, containing hardened feces, on which it contracted closely, was drier than other portions of the tube," etc.

This being the state of affairs, the bowels contracted into the least possible bounds, the consequence would be a collapse of the abdominal parietes, spoken of before as a distinguishing feature of the disease.

The action of the bowels being thus stopped, we would also expect that the stomach would take a *reversed* action, as in ileus, intussusception, strangulated hernia, etc., nature's effort to relieve these conditions. And this, also, we find to be prominently true in Milk Sickness. So that, from a partial paralysis of the organ of life, we would expect *all* the symptoms that this disease presents, just as from *complete* paralysis, we would expect death.

My theory, therefore, of the pathology of the disease, is that it consists primarily in a depression of the powers of the *ganglionic system of nerves*, and secondly, or *immediately*, in a *tonic spasm*, and continuous spastic condition of the *intestinal muscles*.

This theory is *confirmed*, not only by autopsies, but also by the fact that those means which will relax that spasm, and continue the relaxation, are the best remedies for the disease; such as the warm bath, or bleeding, etc., to syncope, where there is sufficient vital stamina remaining, and then keeping up the relaxation by cathartics, *et cætera*.

Treatment.—The treatment consists in sedatives, relaxants, cathartics, enemata, etc., judiciously and perseveringly applied. Each practitioner will have his preferences in making his selection of articles from these different classes of

medicines. Some may be more fortunate than others in their choice. I have my preferences. And I may say that in a thirty years' practice among it, I have been so fortunate as not to have lost a single case of my own attending.

I said above, that the means must be *perseveringly* applied. If one dose is rejected, another must be given, and that "not until seven times only, but until seventy times seven."

A CASE OF SCIRRHUS OF THE PANCREAS SIMULATING ABDOMINAL ANEURISM.

BY M. W. LILLY, M. D.,

Of Grand View, Iowa.

(Concluded from page 423.)

November 26. The tumor was about 6 by 2½ to 3½ inches. It appeared to be the abdominal aorta, or something exactly over it and attached to it. Its pulsations were so strong they could even be seen at a distance of a yard or more by lightly placing the hands on each side of it. By palpation it could be felt to expand laterally as well as in front. It could not be emptied by pressure. The pulsations as strong when patient was prone as when lying supine. On December 8th, the systolic shock and murmur were both distinctly marked, but no diastolic shock. The tumor seemed smaller than on the 26th ult. During the last week of November and first week of December, she had three quite severe attacks of dyspnoea, lasting from one to three hours, and a lighter fourth one.

December 7, evening. Found her in great pain, and nothing remaining on her stomach since yesterday morning. Blistered again; gave Jamaica dogwood and ½ grain of morphia hypodermically. 8 a. m. Blister produced no effect; the dogwood, nor anything else, retained by the stomach. The morphia gave the most complete relief she had experienced in a long time; used same again. The hands, after having been nearly well for a week or more, have again become very red and spotted, but not painful as before.

18th. For the last ten days absolutely nothing has remained on her stomach—neither food, drink, nor medicine. Bowels moved twice themselves, and appeared quite natural in character. Urine red, but free, sometimes markedly so. Morphia, hypodermically, her only relief from pain and vomiting. The pain was indeed torturing, radiating from the epigastric region in all directions. It always precedes the vomiting, and undoubtedly is its cause and not effect. Neither can I think the vomiting caused by the morphia or anything she

attempts to take. On the 15th and 16th it required 1 to 1½ grain every 4 hours, and then only partial relief was obtained. For an hour or two after each hypodermic, she could endure the pain, talk, get a little sleep, and during these hours only. In three hours she begged for the hypoderm again. To-day it takes ¾ grain each six hours. During last twelve days have given per enema every six hours egg 3ss., lime water 3j., and milk and beef tea each, 3iss. Redness of hands all gone. The tumor is smaller.

21st. Since the 18th she can take a very little nourishment and hot water for drink. Has been raising a yellowish-green sputa quite freely. Now uses ½ to ¾ grain hypodermics, each six to eight hours. She is growing weaker fast, but stomach still so irritable and weak I cannot give more nourishment, or stimulants and tonics, even if certain they would do good. The tumor still smaller than on the 18th.

22d to 26th. Had to increase the dose of morphia again to ¾ and one grain. Vomited but little.

26th. She died quietly at 10 a. m., two hours after the last hypodermic. Rational nearly to the last.

Post-mortem, December 27, twenty-four hours after death.

The following members of our County Medical Society were present by invitation: Drs. Hall, Overholt, Grimes, Rogers, and Latta.

We found both lungs adherent to the diaphragm and pericardium. The pericardium thin and translucent; quantity of fluid normal. Muscular structure of the heart soft and flabby, and covered with a small amount of fat. Lungs also adherent to the pleura in front. All these adhesions were easily broken up with the fingers. The stomach, diaphragm, and omentum strongly adherent. Stomach normal in size, save that its walls were very much attenuated, except at the pylorus, where there was some thickening. The abdominal aorta was firmly bound down by strong adhesions, but normal in size and position. Between the stomach and aorta was the tumor, in size about ½ to ¾ inches thick, 1½ inches broad by 5 inches long, extending from the level of the ensiform cartilage downwards, and a little to the right and forwards. The upper or left end—somewhat the smaller—was firmly attached to the aorta. Externally, it was covered with fibrous bands which had attached themselves to the posterior surface of the stomach, to the aorta as before mentioned, also from its lower end as low as the left kidney, to which it was firmly attached, and to the omentum in front. Internally, it was

grayish-white, with small black specks through it, and in a few places yellowish white. It cut dense and crisp. In some portions, the fibrous bands appeared to have extended into and through it. That this tumor, notwithstanding its nearly vertical position, changed structure, and small size at the autopsy, was the pancreas, I have not a doubt. The right kidney was smaller than normal; left one larger and firmly adherent. Liver somewhat enlarged and very friable. A small amount of tubercular deposit in the lower lobe of left lung; remainder of lung healthy. Ovaries normal. Uterus slightly enlarged. The skin remarkably friable—in closing the incision it was remarked, "It sews like through butter"—although a large, dull sacking-needle was used.

Remarks.—This case differed from the typical only:

1. In the skin disease of the hands, due, I think, to chronic inflammation of the pylorus, where we found thickening. Troussseau, Rayer, Chomel, and Wilson Fox, speak of eczematous or impetiginous irruptions, slight attacks of conjunctivitis, and a vinous tint on the malar bone and nose as frequent accompaniments of chronic inflammation of the stomach, and that during days when they were the most marked, the symptoms referable to the stomach were perceptibly alleviated. Also Schmidtmann remarks: "*Novi mulierem in qua herpes faciei cum cardialgia alternabat; extante in facie herpete a cardialgia vacabat; eo disparente, exemplo duris torquebatur ventriculi doloribus.*"—"I know a woman in whom herpes of the face may be alternated with heart-burn (cardialgia), while vacant from the stomach it stands forth with herpes in the face; as it disappears little by little, the pain in the stomach may become severe torture." I see no reason why this vinous tint mentioned should not appear on the hands as well as on the malar bone. You will remember the alternatings of pain from hands to stomach, also the attacks of conjunctivitis.

2. There was no discharge of fats by the bowels, and no enlargement of the lymphatics.

3. The whole gland was involved, I think, by a primary scirrhus, and the post-mortem found it much atrophied.

In conclusion, I would mention the remark of this lady's son, Mr. Henry M. White, after the autopsy, at which he was present. Said he: "The doctors know now what mother died of, but have they learned anything as to the treatment of another case like hers?" Possibly Mr. W. voiced the thoughts of many relatives at post

mortems, and I was glad he thus expressed himself. We often have hard work to obtain post mortems, and is not here an added incentive to us to observe carefully and intelligently on these occasions, that we may have a clear and definite answer to give for the opinions we entertain and express. In other words, we must seek to make them of practical use to the laity and ourselves also. Some contend that "we know and can use only that which we can clearly express in language." I do not quite subscribe to this, but it certainly makes our knowledge more available and the better remembered.

In this case we learned two things: First, negatively, that without the pathognomonic sign of aneurism, do not call it one, and especially do not treat it by compression with the tourniquet; but having it, I think we ought.—Reynold's *Sys. Med.*, II., 868. Second. If a cure could have been effected, I think it was in the line of our efforts.

SOME REMARKS UPON "THERAPEUTIC ACTION AND KINDRED SUBJECTS."

BY JAMES W. YOUNG, M. D.,
Of Williamsport, Pa.,

Read before the Lycoming County Medical Society.

GENTLEMEN: The study of therapeutics is lifelong with the physician, and one worthy of his best efforts. In the presentation of my remarks upon this intricate but interesting subject, I trust I will make myself clearly understood. If I succeed in creating any new interest in this department of medicine, I will be well paid for these few lines.

A physician publishes a plan of treatment successful in his own practice, which, upon being tried by others, fails with many.

Why this happens, is a question of some interest to us. I confess my inability to give a clear solution of the difficulty. Experience has taught most of us that "hope kept alive" and faith on the part of the patient are valuable aids to the effectual action of medicines. That physicians are not equally expert in the use of these peculiar mental forces, is very clear. It matters not how much confidence our patients may place in us, their medical attendants; the instant they recognize the fact that we lack confidence either in ourselves or our remedies, the power of medicine for good is lessened, if not destroyed entirely. Of course I speak in a general way only, for it is well known that this statement will not apply to all drugs. A physician should have as thorough knowledge of the drugs he prescribes as the good

surgeon has of the instruments he uses, and the structures in which he works. It is better to use but a few medicines in the treatment of disease, and understand that few thoroughly, than to handle a multitude and know very little of any. It is admitted by all that many diseases differ in type and malignancy in different localities; and further, that they differ in the same vicinity in different years. Neither should it be forgotten that no two persons are exactly alike, either as a whole or a part—that vital force differs in the same person from time to time, and that it also differs in different persons; and finally, that the mode of death differs in different epidemics, and even in the same one. While this state of things exists, with no two cases alike, we can not expect at all times to get the therapeutic action of certain drugs to which our attention is called in medical literature. The form in which medicine is administered has much to do with therapeutic action. For the sake of convenience, we will divide medicine-takers into three classes, as follows:

1. Those who believe that disease can only be cured by a "strong medicine," or one which tastes disgustingly ugly.
2. Those who are fastidious or squeamish, and call for nothing but agreeable remedies.
3. Those who are satisfied with what we order. As the mind influences the body wonderfully in disease, the peculiarities of these different classes should be taken into consideration in prescribing. I do not wish the impression left, that any medicine should be given which is incompatible with the patient's safety. Tact upon the part of the physician has much to do with success in therapeutics.

Almost every one now-a-days is possessed of the idea that his system is below par, and demands medicines that will build him up. The physician who does not humor his patient in that idea, though he treat him to the very opposite, stands in the danger of either losing his case, or repelling faith and hope, those excellent persuaders of therapeutic action to which we have referred before. This is not all: our client may fall into the hands of a quack or practitioner of some exclusive system of medicine, and not only help fill the pocketbook of our adversary, but get well and sing praises to him and his system for many a day. Thus you see, gentlemen, that while we stand and wonder how it comes that our opponent is so successful, we scarcely ever think of the fact that faith, hope, and nature, cure many patients.

The antagonism of therapeutic agents is a subject which should receive our most earnest attention. Experiments upon animals and men in

health are numerous, and certainly of vast benefit to medical science. Still it must not be forgotten that but very little of it is reliable enough to guide us in the treatment of disease. A vast field remains open to thorough cultivation. The action of the same medicine upon the sick is, as a general rule, wonderfully different from its effects upon the healthy. Here we again encounter a huge obstacle in the investigation of remedies. However, let us not be discouraged, for our work is grand, and one productive of much good. It matters not to what department of the healing art you give the greater portion of your time. Let every man do what he can, for our many minds and talents run in different channels.

I would not have you overlook the influence medicines exert upon each other in combination (or following each other), notwithstanding the tendency of the age is toward the administration of simple or single agents. Our many combinations are growing more simple by lessening the number of ingredients. The medical practitioner who discards routine treatment, and looks with disfavor upon those of his professional brethren who treat disease according to some system of nomenclature, is delighted with the signs of the times. Still it cannot be denied that the efficacy of certain formulas is beyond dispute, and he who disbelieves this statement places himself at great disadvantage. Accurate *clinical* observation is the chief key-note of therapeutic action. It is the rock upon which all investigation must finally rest or be crushed. If we wish to make great advances in the science, we must discard complicated formulas as much as possible, and rely principally upon simple combinations, or what is still better, the drug mixed with some harmless, inert, and agreeable substance. I would like to make some remarks regarding the actions of particular drugs upon each other; but as I have nothing new to offer, nothing unfamiliar to you, I would simply call your attention to the literature of this subject. I would not have you form the opinion that I do not believe in drugs, and depend solely on nature, for then I certainly would have degenerated in my *materia medica*.

It is hard to believe that any living physician would allow intermittent and remittent fevers to run their way without medicine, or let syphilis and other poisonous diseases develop without medication, and be but a silent looker-on.

Our aid is invaluable to nature in the treatment of hundreds of maladies which without our assistance would terminate fatally. I would not practice medicine one day longer did I not feel

fully satisfied that many medicines prolong life by curing and preventing disease, by banishing pain, and aiding nature in a multitude of ways.

A CASE OF CONCEPTION WITHOUT INTRO-MISSION.

BY EDWARD CASS, M. D.,
Of Dresden, Ohio.

In the REPORTER for March 1, 1884, is an extract from the *Gazz. degli Ospital*, October 24, 1883, by Resconi, discussing the subject of conception. The author combats the old opinion that "spermatozoa can make their way into the uterine cavity, if they have already been abandoned only in the vagina. Pallen, Fraer, Rouget, and Kolbert, have all shown the falsity of such doctrine. Experiments on the dead body are then related, which seemed to put beyond a doubt, that semen can enter the uterus only at the time of coition." I have a case to relate that will put beyond a doubt, in practical minds, that conception *has* taken place where it was impossible for the semen to be thrown into the cavity of the uterus. More than a year ago I was called to see a lady in her accouchement, and on making digital examination, I found about two inches and a half within the vaginal canal a firm, unyielding band or curtain, entirely grown across the canal. On the pubic side of this curtain was a small orifice through which I could not introduce the end of my little finger. Through this small foramen must have drained the catamenia. It was her third confinement. Her testimony was this: Some time after the second child was born, she discovered this obstruction in the vaginal canal, and spoke of it to her husband before he had intercourse with her. She was delighted with the discovery, for she thought the obstruction would be an unfailing measure to prevent child-bearing. Some inflammatory action had taken place after confinement, and closed the canal as I found it. By force the band was ruptured, and the labor completed. It required considerable force to rupture the septum. Here, then, is an instance where it was impossible during sexual congress to inject the seminal fluid into the uterine cavity.

Here is a fact—a truth. Here is an accidentally discovered theorem that demonstrates the possibility that the uterus may be impregnated when the "spermatozoa have been abandoned only in the vagina." The American medical professors, in their docility to European speculative teachings, are peculiarly credulous. Since I have

made this narrated discovery, I have doubt that the seminal fluid is almost never thrown into the uterine cavity. This unyielding curtain had no power to dilate the small orifice that speculators claim for the mouth of the uterus. The corollary is plain, without a doubt, that spermatozoa were in this case abandoned quite a distance from the mouth of the uterus. It may be that Pallen, Fraer, and Kolbert, *et al.*, would take this case to be an exceptional one to the rule, that the spermatozoa in the Americans are possessed of greater energy to surmount difficulties than those of other countries—and take into consideration that this occurred in *Ohio, too*, where we find the most determined, enterprising, and aggressive of the race. If this could be copied into every European journal, it might be a cause for them to reflect, and revolutionize a little speculative theory.

HOSPITAL REPORTS.

A CLINICAL LECTURE AT THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

BY WILLIAM PEPPER, M. D., LL. D.,
Provost and Professor of Clinical Medicine in the University of Pennsylvania.

Obstruction of the Small Intestine—Exophthalmic Goitre.

(Concluded from page 427.)

Now as to the vomiting which has been present at one period of this case. It would seem that we should obtain some valuable information from this point. Stercoraceous vomiting is a rare phenomenon, except in connection with actual mechanical obstruction of the bowel, and it is most frequently found associated with mechanical obstruction of the ilium. The narrowing must be at such a position that the contents of the bowel have acquired a faecal character, and it cannot therefore be in the jejunum or very high in the ilium. The occurrence of vomiting of this nature would indicate that, as long as nineteen years ago, there was mechanical obstruction in the bowel.

A not improbable explanation of this case is, that in consequence of ulceration of the follicles of the intestine, occurring perhaps in a child in whom there was some natural narrowing of the bowels, there was produced a contraction of the intestine, giving rise to obstruction to the passage of hardened faeces, to immense distension of the abdomen, and to recurring attacks of stercoraceous vomiting, which continued for seven months; that with the development of the intestine, and possibly with some yielding of the stricture, the obstructed part was enlarged sufficiently to allow life to continue; and that as long as the faeces are liquid or very soft, they can get through, but that the obstruction is always sufficient to interfere with the passage of hardened faeces, and to retard

the passage of softened feces and allow the formation of immense quantities of gas.

From the facts that the appetite is still fair, that the digestion and assimilation are good, that there is no vomiting, no eructations, that the flatulence is intestinal, and the gas passed per anum, I conclude that the great prominence in the upper zone of the abdomen is due rather to great distension of the colon than to dilatation of the stomach. I mention these facts, reserving to myself the privilege of investigating the stomach by direct exploration before deciding positively as to this point.

Is there any other supposition than the one which I have stated which will explain this case? It is needless to say that if any tumor had been forming and gradually occluding the bowel, it would have brought the case to an end long before this. No impaction could have continued as long as this has done under such varying methods of treatment. Some of the curious forms of internal hernias in which the bowel slips into a rent in the mesentery are to be thought of. It is possible that the constriction is due to this cause. Still this is not as probable as narrowing of the intestine, for the symptoms have been so continuous, neither assuming greater severity nor yielding to any considerable degree. If the obstruction were the result of some form of internal hernia, we should expect that at intervals there would have been complete obstruction, and with stercoraceous vomiting. There has, however, only been an average degree of obstruction remaining persistently for eighteen years; and this is more consistent with a certain definite degree of narrowing of the bowel than with any other condition of which I can think.

This supposition makes the prognosis, as regards duration of life, much more favorable, and at the same time shows us that we should limit our efforts at treatment to dietetic management. I should like to try in this case the effect of absolutely liquid food, given in small quantities at frequent intervals. I shall order skim-milk or butter-milk in doses of four ounces every two hours, and gradually increase the amount to six or eight ounces every three hours. It may be that the milk will form too hard masses. If that should be the case, I shall order pepsin and dilute the milk with one-third of its bulk of lime-water, or a little thin oatmeal gruel may be added to break up the masses of casein. If this proves too constipating, I shall go farther and form a peptonized milk, a portion of which will be added to each quantity of milk taken, and he will also receive after each meal five grains of pepsin.

We shall continue this treatment sufficiently long to determine its effect on the immense distension.

Exophthalmic Goitre.

This patient, M. W., was born in Prussia, but came to this country when three years of age. She is now twenty-nine years old. Her mother and one sister died of phthisis. She states that her paternal grandmother had goitre. She was put to work when twelve years of age, and has had to work hard ever since. Soon after going to work, she began to suffer from attacks of palpitation of the heart. She has always been nervous, and worries greatly over trifles. Eleven years ago, the lower part of the left lobe of the thyroid

gland began to enlarge, and five years ago the right lobe began to increase in size. Her friends state that six weeks ago the eyes were not at all prominent, but that since then they have gradually become protruding. She has become excessively nervous, and often has slight attacks resembling angina. Two weeks ago the feet began to swell. She has had to get up at night to pass water, but the urine contains no albumen. Five months ago menstruation stopped, but it has now returned. Previous to five months ago it was natural. She thinks that she does not lose too much.

She has a good appetite, but after eating, feels a weight and oppression in the stomach. When I ask in regard to the condition of the bowels, she states that they are "regular," but further questioning shows that she has sometimes six stools a day. I have hundreds of times been deceived by accepting the statement that the bowels were regular as meaning that there was one natural stool a day, while the patient only meant that there were stools every day, and if there were twenty, all the better. There is such a passion for loose bowels that people will often say that the bowels are regular when there is actual diarrhoea. During the past two years there has been a great deal of diarrhoea. There are at least two stools every day, which she says are of natural consistence.

Here then we have a history of premature work, resulting in breaking down the general system, with the development of nervous symptoms through a number of years, with palpitation of the heart, and as the next symptom with this enlargement of the thyroid, and recently with a little protrusion of the eye-balls. During all this time, the evidences of gastro-intestinal catarrh have been present. From such a history one would naturally suspect this to be a case of exophthalmic goitre, or Graves' disease.

The pulse is 124 per minute, and the action of the heart is quick and jerking. The respiration is so jerking that it is difficult to say whether or not there is a mitral murmur, but I think there is none. There is a murmur heard over the pulmonary valve. This is probably anæmic (hæmic).

The thyroid gland is monstrously enlarged; it pulsates, but is not the seat of a strong thrill. There is a slight thrill. The vessels of the neck are all distended, and the enlarged gland has pushed the sterno-cleido-mastoid muscle far back, and displaced the carotid artery, which is entirely superficial, and pulsates, as you see, directly under the skin. This is remarkable. The artery can readily be rolled under the finger. On the left side the artery is not displaced in this way. Over the right carotid there is no murmur. There is a slight murmur over the enlarged gland. No murmur is heard over the lateral sinus of the brain, where a murmur is sometimes heard; nor is there any over the longitudinal sinus.

We have then a case of marked exophthalmic goitre, of which the protrusion of the eyeballs is the least prominent symptom. The development of these cases varies greatly. The heart trouble, as a rule, begins with palpitation, which may for some time be regarded simply as a functional irregularity of the heart. In many instances, this has been preceded by impaired nutrition resulting from

gastro-intestinal disorder, which is often conjoined with chronic diarrhœa. I have seen so many cases in which this affection has been associated with gastro-intestinal catarrh, that I am disposed to think, either that the catarrh actually serves as a strong predisposing element in the development of the disease, or else that it is the result of an analogous morbid process in the sympathetic ganglia of the abdomen, whose derangement we know often causes diarrhœa, and this may be subsequently followed by a morbid state of the vaso-motor ganglia, governing the action of the heart. I believe that one or other of these relations subsists between catarrhal diarrhœa, lasting through a long period of time and the subsequent development of exophthalmic goitre. Then as most of these cases are in women, we find partly from the nervous disturbance, partly from the anæmia and partly as a predisposing cause, uterine derangement in a large number of cases. There is often menstrual disturbance and ovarian irritation. In this girl the gastro-intestinal derangement has been the most marked feature among the predisposing elements, while the uterine disturbance has only shown itself in the last six or seven months, when she had amenorrhœa for five months, although the menses have now returned.

After the heart has continued in this disordered state for a variable time, thyroid enlargement appears. This may appear early. The gland may enlarge symmetrically, or only one lobe at a time be affected. The enlarged thyroid is the seat of pulsation and often of a thrill. The carotid arteries pulsate violently, and they are at times distended. In the present instance, they are distended, and on the right side displaced. After these symptoms have continued for some time, exophthalmos usually appears, and advances to varying degrees, sometimes remaining slight, sometimes so great that the globe cannot be covered, and the cornea becomes ulcerated from exposure.

During this time the patient grows breathless, exhausted, weak, and anæmic, and frequently we have evidence of this anæmia in the appearance of dropsy. We have in this patient a typical case, with the exception of the exophthalmos. Such cases are often curable, and always can be improved unless the disease has been allowed to go on to the latest stage.

The treatment of such a case consists in the regulation of digestion, the promotion of nutrition, the strengthening and control of cardiac action, the control of nervous excitement, and the promotion of contraction of the enlarged thyroid. Careful hygiene and regulation of the diet is required. An exclusive milk diet sometimes works marvels. The use of digitalis and iron in an acceptable form, the occasional use of ergot, and the use of absorbents, of which iodine and iodoform are among the best, are useful remedies. As a matter of fact, excellent results are obtained from the combination of iron, iodoform, and digitalis.

I shall order for this girl a pill containing one grain of reduced iron and one grain of iodoform, to be taken twice daily and gradually increased to two pills three times a day. Three times a day between meals, she will receive a sufficient amount of digitalis (from eight to twelve drops of

the tincture) to control and strengthen the action of the heart.

This treatment will be continued for two or three weeks, when she will return and report results. We shall have her weighed and the number of blood globules counted.

The diet will be strictly regulated, and will consist of milk, rare meat, and soft eggs. All hard and coarse food will be avoided, so as to prevent diarrhœa. She states that she has been using a good deal of coffee. This must be stopped, for I know of no substance more injurious than coffee.

I think that when we again see her, she will be greatly improved.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Nitro-Glycerine and the Chloride of Gold and Sodium in the Treatment of Albuminuria.

BY ROBERTS BARTHOLOW, M. D., LL. D.

Meeting December 19, 1883.

Hitherto the therapeutics of renal diseases have not advanced in the same ratio as our knowledge of their pathology. It cannot be said now that a cure has been found, but that two remedies of real value are available. My contribution to this symposium on albuminuria, consists in an attempt to define the place which these remedies should occupy in a curative scheme.

How and when are these remedies to be used?

Nitro-glycerine is now administered, as all present know, in the form of the centesimal solution—1 minim of the pure drug to 100 minims of alcohol. The initial dose of this one per cent. solution is one minim, which should be increased until the very characteristic physiological effects are produced. The susceptibility to the action of nitro-glycerine varies greatly, and hence the dose cannot be stated in advance. It is necessary to produce some obvious effect. To maintain the same level of action, a slight increase in the dose may be required from time to time. As the effect is not lasting, the interval between the doses should not exceed three or four hours.

The administration of nitro-glycerine should begin in acute cases immediately after the subsidence of the acute symptoms. It is indicated in chronic cases at all periods, but is more especially useful if given before hypertrophy of the muscular layer of the arterioles has taken place. When it acts favorably, the amount of albumen in the urine steadily diminishes. The mechanism of its action consists in the lowering of the pressure in the renal vessels. How far any curative effect proceeds from action of this remedy on the sympathetic system, remains to be determined.

Chloride of gold and sodium is indicated in the subacute and chronic cases, especially the latter. The earlier it is given the better, if structural changes are to be prevented or arrested. The good effects to be expected from it will depend necessarily on the extent of the damage already inflicted on the kidneys.

The usual dose is $\frac{1}{20}$ grain, twice a day, but this

may be much increased, if necessary. At the outset, $\frac{1}{10}$ grain may be given; in a week the dose should be lowered to $\frac{1}{20}$ grain, and after a month the regular dose of $\frac{1}{20}$ grain should be steadily pursued, with occasional intermissions. Indigestion, gastralgia and colic pains, nausea or diarrhœa, are occasionally caused by it; and if so, the quantity administered must be reduced. It is usually borne without any discomfort, but after prolonged administration, salivation, weakness, emaciation, trembling, and other nervous phenomena, may possibly occur. Such effects, however, are wanting in my experience.

The treatment of albuminuria by nitro-glycerine and the chloride of gold and sodium, does not necessitate the exclusion of other means—hygienic, climatic, or dietetic. These remedies should, however, be given uncombined, at different hours, and their actions should not be hindered or obscured by the effects of other agents given with like purpose. To this general statement there may be two exceptions: with nitro-glycerine, amyl nitrite or sodium nitrite may be given; with the gold and sodium chloride, corrosive sublimate may be combined. If doubts may be felt in regard to the propriety of depending on the utility of these remedies, they need not be long experienced, for if no good effects are observed in two weeks, they may then be discontinued.

The Supposed Connection Between Ear Disease and Kidney Disease.

By Charles H. Burnett, M. D.:

Early writers on disease have shown a knowledge of the fact that alterations in hearing occur in the course of general diseases, as for example, in diseases of the kidneys. It was supposed by them that the alteration in the functions of the ear, in this form of disease, was due to changes in the auditory nerve. But the results of the more reliable modern investigations tend to show that if an ear disease be due to a kidney disease, the lesion usually occurs in the tympanic cavity, and not in the auditory nerve.

Certainly accidents of a hemorrhagic or apoplectic nature might be expected either in the tympanic cavity or internal ear, in Bright's disease, when we reflect upon the deterioration of the blood, and upon the malnutrition and friability of the vascular system, in the later stages of the malady. Further, as Bright's disease is characterized by a tendency to inflammation, especially in serous membranes, and as the membranous structures of the internal ear, or labyrinth, belong to this class of membranes, very naturally organic change in these tissues might be looked for in Bright's disease of the kidneys.

However, as late as 1856, Ran, in his "*Ohrenheilkunde*," published in Berlin in that year, claimed that there was not a solitary reliable observation at that time on record, in favor of any symptomatic relation between the ear and the urinary organs.

In 1869, Schwartz* reported a case of extravasation of blood into the tympanum, as peculiar to Bright's disease, though of rare occurrence; and in the same year, Dr. G. M. Smith, of New York,† "called attention to the fact that impair-

ment of hearing was at times one of the symptoms of Bright's disease, and a symptom which could not be explained by referring it to uremia."

In 1873, Dr. Roosa, of New York, in his treatise on the ear, refers to an obstinate case of suppuration and pain in the middle ear in a man sixty-one years old, suffering from Bright's disease. In this case, it was supposed that the effect of the renal disease upon the tympanic vessels was the cause of the acute suppuration, and it was also supposed that the disease in the drum cavity was originally hemorrhagic in nature. The subject was deemed of enough importance to place a physician on his guard for renal disease, in cases of hemorrhage into the tympanic cavity.

It must not be forgotten, however, that there is a purely sthenic form, otitis media hemorrhagica, occurring in subjects entirely free from kidney disease, in which the only effusion is pure blood, the removal of which from the tympanum by paracentesis, is followed by cessation of pain and return of hearing.*

Again, in 1878, Schwartz† states that serous catarrh of the tympanic cavity, is found in syphilis, heart disease, pneumonia, Bright's disease, naso-pharyngeal catarrh, and apparently may be due sometimes to vaso-motor disturbances. The same author says, hemorrhages into the labyrinthine cavity and the membranous labyrinth occur in kidney diseases.

Also that extravasations of blood into the tympanum (*hæmato-tympanum*) occur spontaneously with acute inflammation in morbus Brightii, cynanche diphtheritica, and in endocarditis verrucosa recens et ulcerosa (op. cit., p. 94).

Dr. Paul Pissot,‡ in an inaugural thesis, is disposed to consider three forms of aural disease, which may arise in Bright's disease, viz.: tinnitus aurium, partial deafness, and complete deafness. His conclusions are, that affections of the hearing may arise at the beginning or during the course of the renal disease. Intermittence seems to be characteristic of these forms of deafness, which may be contemporaneous with the œdema, or may precede it. They appear with all forms of the disease, and are manifested with variable intensity. But he cannot say to what special lesion of the ear, or of the nerve of hearing, their symptoms are attributable. Delacharrière, a responsible aurist, examined the cases upon the history of which the thesis is based, and found rupture of the membrana tympani, abnormal vascularity of the manubrium, and sclerosis of the tympanum, and was disposed to regard the conditions as causative forces. Pissot held that the hypothesis of Rosenstein, according to which there is œdema in the course of the auditory nerve within the cranium, may explain the intermittence and variations of intensity in these morbid manifestations. This latter process may be analogous to œdema of the glottis and vocal cords noted in Bright's disease by Fauvel, in 1864. A similar symptom has been noted by Sée.

In alluding to chronic, non-suppurative aural

catarrh in children, Von Troeltsch* says: "A greater blood pressure from increased action of the heart, as in Bright's disease, must necessarily produce a certain hyperæmia, even in the mucous membranes of the head."

Dr. Albert H. Buck,† of New York, expresses the opinion that in some instances a serous fluid, deeply tinged with the coloring matter of the blood, finds its way into the tympanic cavity through other than inflammatory causes. "Instances of the latter form of disease are very rarely met with, and then usually in connection with a depraved state of the general nutrition, as in morbus Brightii."

Dr. Maurice Raynaud‡ expresses the opinion that diabetic otitis is not only more frequent than is supposed, but that when this has once become a well-known fact, it may prove a pathognomonic index, like anthrax, diffuse phlegmon, and certain erythematous eruptions about the genitals, and arouse suspicion of the presence of the renal disease hitherto unsuspected. He cites a case of well-marked diabetes mellitus, in which there suddenly occurred, one evening, a severe earache, and most carefully watched, so that no chilling could have been the cause of the ear pain. The pain became intense, and toward midnight of the same evening in which the pain set in, there occurred an abundant hemorrhage from the drum-cavity of the affected ear, which was followed by immediate relief. This was followed for several days by a copious sero-sanguinolent, and then serous discharge, which contained leucocytes and albumen, as shown by heat, but no sugar. Post mortem examination, twenty-three days after the attack of otitis, revealed a large perforation in the anterior segment of the membrana tympani, red, fungous and bleeding mucous membrane in the drum-cavity, in which there was a pink, purulent liquid. The ossicles were not dislocated, but were imbedded in granulations, and near the stirrup was a clot of blood. The mastoid cavity was filled with a rose-colored liquid, containing pus-cells, and its bone substance was greatly injected and marbled, presenting all the appearances of inflammation of bone tissue. The labyrinth showed no alterations. The author concludes that otitis in the petrous bone is a peculiar and constant symptom of diabetic otitis.

P. McBride,|| in an article devoted to the consideration of the various causes leading to aural disease, states that "occasionally the ear is affected in Bright's disease by hemorrhage into the tympanic cavity. The tympanum becomes filled with blood, which probably either becomes absorbed or leads to suppuration. Schwartz was, perhaps, the first to observe this condition." McBride further says: "I am not aware that sudden labyrinthine deafness in the course of Bright's disease has been described, but it seems probable that such a contingency might be looked

for here and also in pernicious anæmia, in which retinitis hemorrhagica is not uncommon."

In the recently published work of Prof. Politzer,* on the ear, the author's experience is that in cases in which a supposed connection existed between the organic renal disease and an aural malady, the fundamental cause lay in very apparent changes in the middle ear. He has also found that "catarrhs of the ear run an unfavorable course in tuberculosis, Bright's disease, and all cachexiæ by which the nutrition of the general system has become deteriorated."

CONCLUSIONS.

1. Evidences in favor of either frequent or well-marked aural lesions, dependent upon renal diseases, are extremely meagre.

2. Those lesions in the ear, which have been found in connection with Bright's disease and diabetes mellitus, and which may have been dependent upon the dyscrasia induced by these renal disorders, are in the form of sero-sanguinolent and hemorrhagic effusions into the drum cavity. But the latter must not be mistaken for the sthenic form of otitis media hemorrhagica.

3. From the serous nature of the membranous structures of the labyrinth, organic changes might reasonably be expected in Bright's disease, but positive proof of the occurrence of such lesions based on ante- and post-mortem history is wanting.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Notes of a Case of Inflammation of the Cervical Portion of the Spinal Cord, the Result Probably of an Injury; Followed by Tetanic Symptoms.

BY J. CHESTON MORRIS, M. D.

I desire to call the attention of the Fellows to the following report of an interesting case in which the diagnosis was obscure:

On Sunday, November 25, I was consulted by Dr. ——— about the case of his daughter, an intelligent, lively girl, aged 12, of spare, nervous habit, but generally good health, except that about a year previously she had suffered from slight chorea. He thought she had mumps, but was afraid that the stiffness of her jaws and slight pain in the back and neck, which were all the symptoms complained of, might be due to diphtheria or else to cerebro-spinal meningitis. I told him I thought it was probably only the result of a slight cold, and was rheumatism; if, however, he felt uneasy, he had better send for Dr. Darrach (in whose neighborhood he lived), and, if necessary, I would see her in consultation. Dr. D. telegraphed me to meet him the next morning, and he told me he had found the girl's jaw firmly locked the previous evening, and there was considerable opisthotonos. As we entered the room, a convulsive movement passed over her features, with much suffusion of the face, which soon subsided, leaving, however, a sardonic expression of countenance, and marked opisthotonos. We both thought these convulsive movements might have arisen from dread of my repeating the efforts which had been vainly made the night before to open her jaws; but it was soon evident that this

* Cassell's English Translation, 1883, Philadæ.

was not the case. She complained of no pain, and bore handling and examination well, but nothing further was elicited. Her pulse was about 119, skin and temperature normal or nearly so, tongue slightly furred, respiration rather frequent, but no evidence of lung or heart trouble. She lay on her right side, her head drawn back, with the spinal muscles strongly contracted, and occasionally spasmodically drawn. The abdominal walls were somewhat harder than natural.

Our diagnosis was congestion of the cervical region of the cord, whether of choreic or rheumatic origin we were in doubt, as the symptoms and history gave no clue. Still, the indication seemed to be to allay the spasm, and we directed the administration of full doses of fluid extract of conium, alternated with full doses of opium and belladonna, and liquid nourishment. Dr. Currie assisted Dr. Darrach in charge of the case. I saw her again on Wednesday morning; her pulse had fallen to 104; skin and temperature normal; she expressed herself as rather easier, and wished to be moved to the other side of the bed, which was accomplished, to her relief. The trismus had yielded very slightly; the spasms occurred at longer intervals, but were rather more marked. Dr. D. thought there had been some increase of reflex cutaneous sensibility the day before in the lower extremities, but this had passed away. Careful examination showed absence of the patellar tendon reflex, but the sensitiveness of the skin to touch was normal. Our conclusion was that the spinal congestion had passed or was passing into the stage of effusion, but as it did not seem to be extending, we hoped for a good result. The bowels had not been moved, and were becoming distended with flatus; enemata of flaxseed tea and assafoetida were, therefore, ordered, and previous treatment continued. She, however, soon after became worse; delirium supervened, and she died in a convulsive attack on Thursday, November 29, at 4 a. m.

I requested an autopsy, permission for which was given December 2, "if I still thought it necessary after learning that some three weeks previous to her sickness she had had a severe fall forwards, striking her head so as to make her nose bleed severely; the blood also settled under her eyes." The autopsy, at which only the cervical cord was allowed to be examined, took place at 4 p. m., three days and a half after death. On opening the spinal canal by an incision through the back of the neck and sawing through the vertebral processes on each side, a bloody serum escaped from it; the lining membrane of the canal and the dura mater of the cord were deeply congested, and the cord itself felt softened; it was detached as carefully as possible, and the finger passed up through the foramen magnum into the cranial cavity. The foramen was smooth, but just below it, on the anterior wall of the canal, the odontoid process of the second cervical vertebra was denuded, and felt rough to the finger, almost carious. Unfortunately, as permission had not been obtained for examining the brain, and it was important to avoid disfiguring the body, no ocular demonstration could be made. The portion of the cord removed was placed in the hands of Dr. Morris Longstreth, with the above history.

The case seems to me to be a very interesting and instructive one. An injury by *contre-coup* to the odontoid process, followed by inflammation of the spinal cord and tetanic symptoms coming on insidiously three weeks after the injury, in the case of an individual of choreic, rheumatic antecedents, was perhaps hardly to have been diagnosed more correctly with the information we had. I may add that her uncle, the son of one of the Fellows of this College, died of fracture of the cervical spine, the result of an accident, some thirty years ago.

I also subsequently learned that she had complained of pain in the back of the neck, after the fall, to the cook, and her mother informed me when I first saw her that she had for several days previously spoken of slight pain in the upper and middle part of the spine, which she supposed to be rheumatic or due to a slight cold taken while gathering walnuts. She also noticed on these days a peculiar drawn expression of the face, which occurred while she was at table, when the stiffness of the jaws was first noticed, which gave rise to the supposition that she might be getting mumps.

Dr. Morris Longstreth submits the following note on the examination of a portion of the cervical spinal cord.

The substance of the cord is slightly softened. The larger vessels of the pia-arachnoid are very full of blood, and very conspicuous. The general aspect of the surface is pinkish, indicating an injection of the smaller vessels. A cross-section of the cord presents nothing to note. The inner membranes can be more easily separated from the cord than normal, and it is apparent from their examination that there exists a slight exudation which renders their tissue somewhat opaque.

The microscopic sections were made, after a short immersion in alcohol and subsequently in Muller's fluid, by freezing. The tissues of the membranes appear swollen, their fibres are separated, and in places the interstices show a minute amount of exudation materials. The inflammatory material is seen also on their outer surface, but the amount of it is not considerable. It is composed of fibrinous threads in which are entangled a small number of nuclei. The blood-vessels are large, the swelling also affects their walls, and many of them contain blood corpuscles and clots. The specimens—those that were stained with a carmine fluid—show these parts deeply colored, and the nuclei are unusually conspicuous.

On the inner surface of the membranes toward the cord, the inflammatory changes of the same character are also seen; they extend into the substance of the cord but a short distance. The portion of the cord at its surface is markedly granular. The same changes are found in the portions of the membranes which extend into the anterior and posterior fissures of the cord, but at these parts the morbid condition is less distinct. The blood-vessels, ramifying in the substance of the cord, show slight alterations of a similar character, and around them at a few places there appears a very slight exudation in which the nuclei stain deeply.

The nerve tubules and the ganglion cells of the cord show no appearance of change. The tissue of the cord, however, showed some alterations.

Its general appearance was more granular than normal; this change was irregularly distributed, more marked always near the surface, but uneven in the depth of its extension. It is uncertain whether it is more marked around the capillaries in the interior of the cord, where it is often conspicuous in cases of tetanus. It must be noted that the effusion around these capillaries is very slight, however. The change of this tissue can be described as a granular disintegration, and, judged by its character and its situation, was probably induced by inflammation of the membranes affecting the contiguous parts of the cord. In one or two places, bundles of nerve filaments (cross-section of the spinal nerve roots) are seen attached to the outer surface of the membranes. Around these bundles and among the fibres, the inflammatory changes are especially well marked.

Remarks on the Post mortem Changes and the Microscopic Appearances.—The post mortem changes, taken in connection with the history and symptoms, show that the tetanic spasms were due to the inflammatory condition of the cord. The inflammation was most marked at the portion of the

cord from which are derived the filaments of the nerves distributed to the muscles alone implicated in the spasmodic contractions. It would seem that the impress was communicated directly to these nerves, probably before their exits from the dura mater, since we see the inflammatory changes conspicuous around some of the filaments of which they are made up.

The changes in the cord, as here seen, are not of the character found in tetanus; at least they do not equal in degree those usually found. Here the vascular exudation is very slight or entirely wanting, and the granular disintegration is slight and localized, and evidently communicated from the inflammation of the membranes. In tetanus we have no inflammation, the changes consisting of exudation, mostly or entirely fluid, which leads to granular alterations of the tissues of the cord. Here we have a very evident, though slight, inflammation, which has produced somewhat similar alterations of the cord, partial and much less in degree, and only approaching the tetanus changes in kind.

EDITORIAL DEPARTMENT.

PERISCOPE.

The Pathological Relations and the Etiology of Diphtheria.

Dr. Edward F. Willoughby thus writes in the *Brit. Med. Jour.*, March 1, 1884:

1. 1. Recent microzoic pathology has established beyond doubt in some cases, and presumably in others, that infections and infective diseases, with a few apparent exceptions—if, indeed, they be exceptions—are caused by, dependent on, or constantly associated with, the presence of certain more or less differentiated forms of bacteria.

2. We are justified in considering these as specific—though, as in the case of the ova of man, ox, and dog, the specificity of which is clear enough, our visual organs may not be able to distinguish them—by the specific character of their effects in the body, the contagium of each disease producing the same, and not another.

3. Yet there is reason to believe that these specific forms may be evolved—except in the case of some of the most highly differentiated, as small-pox, the conditions necessary to whose evolution do not now exist—from non-specific and inert forms; and that thus some diseases, afterwards and usually propagated by contagion, may at times be evolved from extra-corporeal or other bacilli; in other words, may arise *de novo*, though not *de nihilo*.

4. These lower forms of bacilli, non-specific, but capable of developing into higher and specific forms, as well as the necessary conditions for their development, are most likely to be found in and among the processes of putrefaction of organic matter—processes themselves invariably set up by like organisms; and such diseases are thus, as

Murchison maintained, against Jenner regarding enteric fever, *pythogenic*.

5. While history and medical observation warrant us in denying such evolution, under existing social and sanitary conditions, in regard to small-pox and measles, and leave the cases of typhus and scarlatina open to differences of opinion, there is an overwhelming mass of evidence in favor of its frequent occurrence in enteric fever, and still more of diphtheria.

6. Bacilli of a more or less infective character are present in most forms of pharyngitis and tonsillitis, whether induced by exposure to and absorption of septic poisons, or by the usual causes of catarrh.

II. *Diphtheria* may be defined as an infectious and specific, though, perhaps, not highly differentiated disease, marked by some or all of the following phenomena. Locally, there is an inflammation of all or any part of the fauces, tonsils, pharynx, nasal passages, and larynx, characterized by the exudation of lymph rich in fibrine and proliferated epithelium cells and leucocytes, leading to submucous thickening and the deposition on the surface of a so-called false membrane of any degree of thickness and consistence. Generally, there are blood-changes or derangements of innervation and nutrition, manifested not only by pyrexia and albuminuria as in scarlatina, but by certain characteristic phenomena, viz., paralysis of the heart, of deglutition, and, perhaps, of voluntary muscles, of the nerves of special sense, and derangements of common sensation; these phenomena differentiating it from non-specific pharyngitis.

The local dangers are:

1. The liability of this exudation to putrefaction and the absorption of the putrid matter.

2. The obstruction of the glottis by the exudation.

3. The paralysis of the glottis, due to the inflamed state of its muscles, causing its margins to collapse during inspiration, while expiration is unaffected.

That this, and not spasm, is the cause of the suffocation is evident, because—

1. Muscles actually inflamed are not subject to spasm, but rather to loss of contractile power.

2. So long as the glottis is not obstructed by membrane, expiration is not impeded.

3. Identically similar respiration follows division of the laryngeal nerves, *i. e.*, artificially produced paralysis.

4. Is also heard when artificial respiration is performed on the dead body in which the glottis is passive.

III. *Diphtheria and Croup*.—Croup is an equivocal expression, being popularly applied to any cough marked by a peculiar brassy sound, indicating its origin in any abnormal condition of the larynx. It may thus mean—

1. Simple or catarrhal laryngitis.

2. Laryngismus or true spasm of the laryngeal muscles, arresting, during its continuance, both inspiration and expiration.

3. Laryngeal diphtheria.

The last name is by some physicians restricted to cases of diphtheria, originating in the larynx itself; but identical symptoms and consequences follow the extension of the diphtheritic process from the pharynx to the larynx; and such a distinction is unscientific, and without any practical value.

"Croup," therefore, if not simply catarrh, or a reflex spasm of the glottis, is, and should be called, diphtheria.

IV. *Diphtheria and Tonsillitis*.—In catarrhal tonsillitis, the increased and altered secretion of the tonsils thickened by cell-proliferation distends and protrudes from the crypts in the form of whitish points, which may ultimately coalesce, undergo putrefaction, lead by absorption to inflammation, and even suppuration of the cervical and submaxillary glands, or assuming a fibrinous character simulate diphtheria; but in such cases albuminuria, and the nervous derangements characteristic of diphtheria, are absent.

More often the inflammatory process is localized, and pseudo-abscesses in the tonsils, and enlargement of the neighboring glands, are the only consequences.

V. Though the great majority of cases of tonsillitis and pharyngitis are purely catarrhal, set up by exposure to cold and wet, to irritants, etc., experience places it beyond doubt that they may be produced by the absorption of septic agents, as sewer-gas, etc. Between these cases and well-marked diphtheria it is impossible to draw any satisfactory line of demarcation, and we are justified by analogy as well as by clinical observation in believing all such cases of septic tonsillitis and pharyngitis to be essentially the same as diphtheria.

By analogy, even in those fevers whose lesions are usually visible and unmistakable, we meet with obscure and unrecognized cases, cases whose true nature is only revealed by their remoter consequences, as albuminuria in scarlatina, or even by

their merely giving rise by infection to other cases which admit of no such doubt. We have small-pox with one pustule, and why not with none? scarlatina without visible eruption, enteric fever marked only by slight intestinal derangement and malaise or weakness, and so on.

Clinically, I have seen three sisters with what seemed to be a common foul-smelling sore-throat, but in one of whom fatal laryngeal symptoms rapidly developed, she being a feeble child of five, and they healthy girls of fourteen and sixteen years. In none was there any visible exudation on fauces or pharynx.

I, therefore, firmly believe that diphtheria is of far more frequent occurrence than is commonly supposed, and that all, or nearly all, cases of sore throat evidently connected with unsanitary surroundings, and affecting, simultaneously or consecutively, several members of a family, are to be reckoned as diphtheria.

VI. *Etiology*.—The connection between sewer-gas and fecal or other putrid accumulation in or around dwellings, and diphtheria, has long been recognized by medical men, especially those resident in towns. But, of late, several rural practitioners and medical officers of health have advanced a theory of meteorological causation. Dr. C. Kelly, medical officer of health for West Sussex, insists on the fact that, while diphtheria is scarcely known in Worthing, it is very prevalent in the rural districts; and he attributes it to exposure to cold and wet in going to and from distant village schools. In the reports of the German Imperial Board of Health, I observe that it is at times fearfully prevalent in the rural districts of Saxony; and, in those of the Board of Health of Michigan, I find that among the sparsely-peopled settlements in the backwoods, amid foul and stagnant pools, etc., its ravages surpass all example.

I do not deny the facts adduced by Drs. Kelly, Slane, King, etc., but I do their inferences; for where does one meet with foul dunghills, pigsties, etc., in close proximity to houses, saturating the soil with putrescent matter, or with cesspools side by side with wells, more frequently than in such villages and rural homesteads?

Again, it is remarkable that, in Munich, as Dr. Soyka has shown, enteric fever prevails most in those quarters provided with old and pervious sewers, next in those with good sewers, but where the houses are not properly disconnected therefrom, and least in those without any sewers at all; whereas diphtheria is constantly present in the latter, drained only by the *Stadt-bäcker*, and with cesspools dug in the porous rock. Thus, diphtheria and enteric fever exist in Munich side by side, but in inverse proportions, in the several quarters of the city. In fact, it would appear that surface-accumulations of filth are more likely to generate diphtheria, and pent-up putrid gases to produce enteric fever.

Hypodermatic Injections of Calomel in the Treatment of Syphilis.

The *Med. News*, quoting from the *Annales de Dermat. et Syphil.*, says;

It being granted, says Dr. Louis Jullien in a recent note on this subject, that the hypoder-

matic treatment of syphilis is the preferable method, what mercurial preparation shall we use? While Lewin, of Berlin, and the majority of practitioners, have expressed a preference for soluble and easily-absorbed preparations (the bichloride and the peptonate of mercury), Scarenzio has recommended the use of calomel, in suspension, as a very manageable preparation. The first experiments of Scarenzio were made in 1864. Now, twenty years after, his method has received new attention.

The formula first used by Scarenzio was:

Calomel,	gr. ii.j-ivss.
Glycerine,	℥ xxv.

Smirnof modified this formula to one part, by weight, of calomel, to ten parts, by weight, of glycerine. At each injection about gr. ii.j. of alcohol were thrown into the cellular tissue; but in feeble and anæmic women only about gr. j. was used. Scarenzio still further modified this form by using mucilage:

Calomel,	gr. $\frac{3}{4}$ -ij.
Powdered gum Arabic,	gr. $\frac{3}{4}$.
Distilled water,	℥ xv.

The needle of the syringe used should measure at least one inch long. This is important, as in women especially, and in men sometimes, a small abscess will form at the end of the track made by the needle, and the inflammation extend up through it.

As to the choice of locality for making the injection, the posterior part of the upper arm is preferable, then the back and the back part of the shoulders. Smirnof says:

1. The substance injected *between* the skin and the muscles is not exposed to pressure.

2. The integument over the buttocks is so thick and firm that, even if the injection causes inflammation, the small quantity of pus formed will not reach the surface, but will be absorbed. After having chosen some point at which to make the injection, the skin is pinched up and the needle passed under it, but not into the muscular structures.

The effect of the injections, in the treatment of the secondary manifestations, is very quickly seen. All who have used the method of Scarenzio, declare that the period of illness for each syphilitic has been greatly diminished by it. The promptness with which the secondary eruption disappears is greater than with any other remedy.

The action of calomel injections is, according to Smirnof, much more energetic than that of other remedies. Smirnof also insists upon the value of this method in the manifestations of the tertiary stage. Pirocchi and Porlezza have already cited the case of gummous syphilis of the brain cured by two injections, and several others of periostitis and osteoscopic pains. Calomel injections are well borne by young children. After the injection of gr. $\frac{6}{13}$, $\frac{7}{11}$, or $\frac{9}{10}$, they do not appear to suffer, and become quiet. In cases of older children, injections of gr. $\frac{9}{10}$ to ii.j. are sufficient to cause the complete disappearance of all manifestations, whether secondary or tertiary.

As to the number of injections, Scarenzio's first views have been proved to be well founded. Gr. vj. of calomel are ordinarily sufficient to cause all syphilitic accidents to disappear. This repre-

sents four injections of gr. iss., given two at a time, the interval between the first and second two being three weeks. These four injections will replace all the arsenal of pills, frictions, washes, etc., and the patient only needs the physician once in three weeks.

Tubercular Meningitis.

The *London Med. Record*, January 15, 1884, tells us that Dr. Wortmann contributes (*Jahrbuch für Kinderheilkunde*, Band xx., Heft 3), a long and valuable analysis of fifty-six consecutive cases of this disease; thirty of the patients were girls, and the ages were from ten months to eleven years, about three-fourths of the whole number being from two to five years old. All but six were poorly nourished on admission, and twenty-five had enlarged glands. A family taint could be traced in twelve. The first symptom of the disease proper appeared to be vomiting, which took place usually once or twice a day, or oftener; but very seldom occurred at night. It nearly always ceased when the pulse became slow, though in one case it continued throughout, and could not be subdued. Contrary to the experience of many, in five cases the vomiting returned after a cessation of from two to four days. In four patients vomiting was absent. Constipation was present throughout in forty-two cases; in ten it gave place two or three days before death to involuntary motions; while in the remaining four, diarrhœa persisted throughout the complaint. Headache, with one exception, was a constant symptom. The abdomen was markedly retracted in thirty-four cases, and moderately so in the rest, but the author's experience did not support Vogel's view, for in only three was there any apparent tonic spasm of the abdominal muscles. Irregular respiration was never absent; but as the end approached, it usually gave place to severe dyspnœa. The pulse appears to have followed the recognized course. It became rapid a few hours before death in every case. Fever was present even in the prodromal stage. In the first stage proper, it was never over 104°, and showed morning remissions of nearly two degrees. When the pulse became slow the temperature began to fall, but was some days before it reached the normal point. In sixteen, however, it rose instead of falling; and six of this number were without complication. In the third stage the temperature varied very much in different cases; but, as a rule, either rose or remained the same. Occasionally it fell, and in two cases it sank to 89.6. Shortly before death it suddenly rose, in uncomplicated cases, to a great height, as *e. g.* from 99° to 106°. After death, the temperature rose moderately where it had been previously high for some time; but, where the rise had been sudden, it rose a great deal; in other cases, it gradually sank after death. Retraction of the head was present in all but one case, and commenced when the pulse became irregular; in one the head was drawn towards the left as well as backward, and here a large tubercle was afterwards found on the left side of the cerebellum. Hyperæsthesia was present in all but one of those cases in which the spinal meninges were involved. Herpes zoster appeared in one of these cases. The urine was

carefully examined, but showed no constant alteration; the urea was sometimes increased, sometimes diminished. Photophobia was a frequent symptom. The pupils in the first stage were chiefly remarkable for their sudden variations, without any corresponding changes in the amount of light. When the pulse became slow and irregular, the pupils dilated and were sluggish. A transient difference in the size of the two pupils was frequently observed, but appeared to have no connection with the position of the child. On the pulse becoming rapid again, the reaction to light was generally lost, and the pupils were either contracted or of normal size. The ophthalmoscope was used in twenty-seven cases. Of these, twelve presented a normal fundus, four showed tubercles on the choroid, ten venous hyperæmia of retina, and amongst these were four with optic neuritis. One case showed hemorrhages and cloudy papillæ (on autopsy large tubercles were found in the cerebellum, but no nephritis). Nystagmus was observed five times, ptosis six times. General convulsions set in, with commencing coma. Partial convulsions, which affected chiefly the face, appeared earlier; the pupils became dilated during the paroxysms. Paralysis, which, however, was never complete, affected in different cases the eyes, face, and extremities. In the last it was preceded by clonic spasm of the part affected. The *tache cérébrale* was present, in a varying degree, in the majority; but flushes, alternating with pallor, of the face, were remarked in all. The skin was dry until near the end, when sweating broke out. The duration of the disease was from six to forty-five days, with an average of eighteen.

The necropsies showed general miliary tuberclosis in forty-five out of the fifty-six cases. Cheesy deposits, chiefly in the bronchial and cervical glands, were found in all. The spleen was tubercular, either in substance or on the capsule, in every case. It was enlarged in twenty-eight patients. The mesenteric glands were always enlarged, and in fifteen cases they were cheesy. The exudation at the base of the brain was of a more or less gelatino-purulent character; it frequently extended forward so as to involve the olfactory lobes. The convexity was involved in fourteen cases, but there was no case in which the convexity alone was affected. The ventricles were dilated. The choroid plexus showed tubercles in nineteen cases, and contained a moderate quantity of blood in all. The spinal cord was examined in the last twenty-seven cases. In four of these, no change was found. In the remainder the spinal fluid was increased, and often turbid. The pia mater, especially in its posterior aspect, was thickened, yellowish, and tuberculous, in direct proportion to the duration of the disease. In four, the dura mater was thickened, and in two cases the spinal cord was the seat of a large solitary tubercle.

Operative Interference in Irreducible Luxations.

The *London Med. Record*, March 15, 1884, says that M. G. Poincot, of Bordeaux, in an able review on direct operative intervention in irreducible luxations (*Revue de Chir.*, No. 8, 1883), has collected a number of interesting clinical records, on which are based the following conclusions.

Luxations, if studied with regard to the feasibility of operative treatment, may be arranged in three classes:

1. Recent luxations that have not existed longer than eight days, and in which the process of repair has hardly begun.

2. Luxations which have existed for more than fifteen days, but have not passed beyond the general limits assigned by authors to irreducibility; these M. Poincot would call intermediary.

3. *Old* luxations, being such as have passed beyond these general limits.

In cases of the first class—that of *recent* luxations—the indications for operative interference must be very limited. The works of Bigelow on luxations at the hip, of Kocher on those at the shoulder, and of Farabeuf on those of the thumb—the most exposed amongst articular displacements to irreducibility—have shown that the obstacle to reduction is formed almost exclusively by a certain portion of the capsular apparatus, and have made known the most rational and efficacious means for overcoming—or, rather, for turning—the difficulty. The number of rebellious forms of recent luxation have been much reduced, and operative intervention in this class is seldom permissible, save in cases of obstinate luxation at the ankle and of the thumb. M. Poincot advocates tenotomy in the treatment of irreducible luxation at the ankle, and states that backward displacement of the thumb (if it resist attempts at reduction by over-extension or by circumduction) may be justifiably treated by subcutaneous section. Arthrotomy and articular resection are quite out of the question in dealing with recent luxations. On the other hand, arthrotomy, followed or not by resection, is justifiable in certain of the so-called intermediary luxations; as, for instance, in cases of luxation at the shoulder when the limb is rendered powerless through compression of nerves; in cases of antero-posterior luxation at the knee, with symptoms of vascular compression; and in cases of luxation of the thumb, where the free use of the hand is impeded. In every other instance of this second class of luxation, laying open the joint ought to be rejected. Even in the above-mentioned exceptional cases, in which operative intervention is permissible, arthrotomy should always be preceded by subcutaneous section of ligaments and tendons, and, if necessary, of adhesions. In cases of *old* luxations, as in those included in the two preceding classes, subcutaneous section (according to M. Poincot) should occupy the first place. In dealing with the question whether—if reduction remain impossible after such sections—arthrotomy should be practiced, a distinction, it is stated, ought to be made between ginglymoid articulations, which are formed in one segment by two bones, and enarthrodial articulations, in which there are but two opposing bones. In the former kind of articulation, as the elbow, the knee, and the ankle, arthrotomy seems to M. Poincot to be the best mode of intervention. In an irreducible luxation of long standing of an enarthrodial joint, osteotomy is preferable to arthrotomy, which is to be regarded here as a useless and dangerous operation. An exception, however, is made in the case of irreducible luxa-

tion of the thumb, as here a serious and impeding deformity can be removed by resection alone.

Incubation of Infants.

The *Med. Press*, February 27, 1884, says:

The results obtained by the aid of an incubator for rearing infants have just been published by M. Auvard, resident at the Maternity Hospital, in his *Archives de Tocologie*. The first incubator was used in Paris by M. Tarnier, and consists of a large wooden case divided into two portions, the lower of which contains warm water, while the infant is placed in the upper one.

FIG. 1.

At first the incubator was heated by means of a thermo-siphon, but this system has been abandoned, fearing that through the negligence of the attendants the lamp would be left alight too long. The apparatus is now heated by filling the reservoir with boiling water both morning and evening, and thus a mean temperature of 30–32° C. is kept up. The child is clothed in the usual garments, because, if the skin was in contact with the air at a temperature of 32° C., it would lose some of the animal heat, and when taking out the infant to feed it, the danger of cold would be very great were it unclothed. Among the different cases (151 in number) in which the incubator was used, there were 93 infants which were born prematurely. Of these, 31 died. M. Auvard based his statistics on the weight of the children, and discovered that among those who weighed less than 2,000 grammes the death-rate was at the "Maternité," 66 per cent.; at that of Paris, 65 per cent.; while in those places where the incubator was used, it was only 38 per cent. In the treatment of oedema, which is a serious infiltration of the tissues caused by the bad state of the infant when born, and the rigors of the exterior temperature, and in which, as a rule, 16 out of every 20 cases die; when the incubator was employed, only 4 of the 25 placed in it failed to recover. It has been said that children brought up

in this way die when exposed to the outer air, but such is not the case, as M. Auvard conclusively proves. It has also been stated that immature children placed in the incubator only live one or two months, viz., until the time arrives in which they ought to have come into the world; but this objection is not founded on any scientific basis, and is therefore not of any value. M. Winckel, of Dresden, has started a new theory of permanent baths, but we have not investigated it sufficiently to form any opinion.

Gangrene of the Abdominal Integument Following Puerperal Parametritis.

The *London Med. Times*, February 23, 1884, says that Dr. M. Thiede, of Lübeck, relates two cases of the above rare kind in a recent number of the *Zeitschrift für Geburtshilfe und Gynäkologie*. He has not been able to find any previous description of this complication. The first patient, aged 27, delivered of her second child, went on well for eight days. Then she began to have abdominal pain and headache, with sleeplessness and febrile symptoms, and the lochia, which were purulent, became again sanguineous. The hæmorrhage from the uterus continuing, in spite of general treatment, on the 17th day of the lying-in the interior of the uterus was explored under anæsthesia, some outgrowths from the placental site removed, and the cavity washed out with a carbolic acid solution. From the second day after this treatment the bleeding completely ceased; but febrile symptoms continued, and a firm parametric infiltration developed around the cervix. Signs of cystitis then appeared, and to this was soon added a tender swelling of the integuments on each side along Poupert's ligament. This continued to spread till it reached to within three fingers' breadth of the navel. The swelling was at first hard, then became soft and boggy. On the 23d day after the operation vesication appeared, then subcutaneous abscesses, and finally the skin sloughed in one piece, leaving a granulating surface reaching from one iliac spine to the other, and to the height already mentioned. Aided by skin grafting, this healed up, and the patient did well. The second patient was aged 25, and had had three children and one miscarriage. A second miscarriage at the third month occurred; and for three days after this the patient went on well. Then came profuse hæmorrhage; and a piece of placenta projecting from the os was removed. This did not stop the bleeding; and therefore, under chloroform, the uterus was explored, the remainder of the placenta removed, and the cavity washed out with carbolic acid. Next day a rigor occurred, and on the sixth day an exudation was to be recognized in the right parametrium, which soon extended behind and to the left of the uterus, and slight cystitis came on. On the twentieth day after removal of the placenta, fresh symptoms appeared, severe pain was felt in the lower abdomen, and there was redness, swelling, and tenderness of the skin over the symphysis. In the left inguinal region were inflamed lymphatic vessels. The inflammation spread; vesication, and then gangrene of the skin took place, an ulcer being left measuring about thirteen centimetres by six. There was also suppuration of

inguinal glands on both sides. The patient recovered after an illness of about thirteen weeks' duration. Dr. Thiede attributes the gangrenous inflammation to septic infection, the skin being predisposed to slough by the pressure and bruising of it necessarily involved in bimanual manipulation of the uterus. We may also mention (points to which Dr. Thiede does not attach much importance) that the patients had been treated, prior to the gangrene, with mercurial inunction, and the application of ice to the hypogastrium. The ice, he says, gave great relief to the pain of the parametritis, so much that when it was removed the patient clamored for its replacement.

Plaster Supports.

Dr. W. T. Browne thus writes in the *Boston M. and S. Jour.*, March 20, 1884:

The object is to produce fixation with a material which shall be easy of application and easy of removal, being cleanly, light, durable, cheap, and ready for use as soon as one is done applying it. This may be attained by the use of plaster of Paris in the following way, for a support of the spine for instance:

Take three, four, or five pieces of plaster gauze as wide as the support is to be, and long enough to go around the body and lap ten or fifteen centimetres each way. Lay these on another piece of the same length and eight or ten centimetres wider, and stitch them all together in the middle of their length, so that the seam shall extend up and down the front of the completed support; rub cosmoline into this seam in as narrow a line as possible. Hold the layers of gauze up to the body, so that the seam shall come over the sternum and the widest layer next the body, and cut out where they come under the arms and in the groins. It is not necessary to be very particular about the cutting, as the edge can be easily turned over the required amount, after the plaster has been applied and before it has set.

The patient, having on the usual thin undershirt that fits well, and without any pads, is suspended in the usual way.

Eight hundred or one thousand grammes of plaster are now mixed with water to the consistency of cream, and while an assistant holds the gauze up to the body, the first layer is brought down smoothly and rubbed with plaster, then the next, and so on till all have been laid and filled with plaster; then turn the edges of the widest layer over the others, thus forming a binding and a smooth edge.

The plaster may be put on with a brush or with the hand; I prefer the hand. It requires about fifteen minutes to apply the plaster, so it should not set quicker than that.

Such a support is cleanly, for the edges being bound are not liable to crumble.

It is much lighter than when put on with rollers, as it does not need to be as thick, owing to plaster all being mixed at once and setting in a uniform mass.

A bandage made in this way is two or three millimetres thick in front, and four or five behind, and will last three or four weeks. If it is wanted to last longer, it may have more gauze and more plaster.

The cost of material is only a few cents, and the plaster will be found to be very thoroughly set by the time the binding has been turned and the surface rubbed smooth.

The plaster should be tested before using, to ascertain how long it requires to set; and, if it requires a few minutes more than by experience it is found to take to apply, it may be mixed a few minutes before required for use.

When it is necessary to remove the support, it may be ripped open along the seam as readily as any seam in cloth.

It requires less experience to apply a bandage in this way, as it is impossible to draw it tighter in one place than another and produce ridges on the inside.

Hepatic Colic—Inflammation of Gall Bladder—Perforation—Peritonitis—Death.

Dr. E. L. Larkins reports this case in the *Peoria Med. Mo.*, September, 1883:

On the morning of August 11, 1883, I was called to see a patient, a boy of delicate constitution, aged about nine years.

The parents gave me the following history: Four days previously the patient was suddenly seized with severe pain in the right hypochondrium, of a paroxysmal character, vomiting at first of the contents of the stomach, and subsequently of thin mucus, streaked with blood. The patient had rigors, followed by fevers of a remittent character. On the second day of illness there appeared, they said, at the inner margin of the right rectus muscle, just below the ribs, a tumor a little larger than a hen's egg, which could be traced upward to the liver. This, they told me, continued to increase in size until some time in the night previous to my being sent for, when it entirely disappeared. Following the disappearance of the tumor, there appeared great prostration with, in a few hours, rapid swelling of the abdomen.

When I arrived I found the patient *in articulo mortis*, body bathed in a cold perspiration, extremities cool, pulse 180, temperature 101, respiration short and irregular, mind clear, and complained of pain when the abdomen was touched. I informed the parents of the near approach of dissolution, my prognosis being verified, as the boy died in about four hours.

The gall bladder must evidently have been perforated, and the contents escaping into the abdominal cavity, set up violent peritonitis, which was speedily fatal.

Rhode Island Medical Society.

At the quarterly meeting held in Providence, March 20, 1884, the following papers were read: "Topical cardiac blistering in the treatment of acute rheumatism," by Dr. Neil O'Donnell Parks. "Prevention and treatment of puerperal fever," by Dr. H. Terry. "Blepharospasm," by Dr. H. G. Miller. "Disease of the bladder, probably malignant," by Dr. Burge. "Impacted intracapsular fracture of the neck of the femur," by Dr. Lloyd Morton. The officers of the society are, Dr. Job Kenyon, President; and Dr. George D. Hersey, Secretary.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

The COMPENDIUM, formerly published every six months, appears now *every three months*. It is compiled with special reference to being taken *with the Reporter*, and none of the articles which appear in our weekly are reproduced in our quarterly publication. It is made up exclusively from other sources.

Each number of the *Quarterly Compendium* contains 150 pages of reading matter, carefully selected from American, British, and European medical journals, with a special view to the wants of the American physician. It is on excellent paper, and neatly bound in pamphlet form, with full table of contents and index.

The price of the COMPENDIUM is 75 cents a number, or \$2.50 a year; and it will be found well worth it. But when taken with the REPORTER, we offer the two journals at the very low price of SIX DOLLARS, when paid for *strictly in advance* and directly to this office.

SPECIALISM.

Every once in a while we hear some man most savagely abuse *specialists*, and condemn them and specialism in the most unqualified terms. Now, this is wrong. If a specialist will confine himself within the limits that belong to him, then is he not only not to be condemned, but he must be regarded as a necessity to the proper and complete fulfilment of the healing mission of our profession. But what is their proper sphere? They are aids to the general practitioner. Just as the general of an army has his adjutant-general, and his commissary-general, and his quartermaster-general, and so on, all of whom have each their separate and distinct duties to perform, which are all carried out in the interest of the commanding general, and are designed to enable him to best conduct and manage the whole; so the general practitioner should have his oculist, and his aurist, and his neurologist, and so on, to whom he can refer any patient that may, in his judgment, require these special services, provided the patient has the money to pay for them. Dr. Allbutt, in an address recently delivered in London (*Lancet*, March 15, 1884), thus arraigns the gynecologist. He says that "a neuralgic woman" (he is speaking about abdominal neuroses) is either told that she is hysterical or that it is all uterus. In the first case she is comparatively fortunate, for she is only slighted; in the second case she is entangled in the net of the gynecologist, who finds her uterus, like her nose, is a little on one side, or again like that organ is running a little, or is as flabby as her biceps, so that the unhappy viscus is impaled upon a stem, or perched upon a prop, or is painted with carbolic acid every week in the year, except during the long vacation, when the gynecologist is grouse-shooting, salmon-catching, or leading the fashion in the Upper Engadine. Her mind, thus fastened to a more or less nasty mystery, becomes newly apprehensive and physically introspective, and the morbid chains are riveted more strongly than ever. Arraign the uterus, and you fix in woman the arrow of hypochondria, it may be for life."

Though rather harshly expressed, it must be

conceded that there is much truth in what Dr. Allbutt says. It would be only natural that the specialist, who is confining himself to the diseases of one organ, or one set of organs, should view all diseased conditions from a partial standpoint, while the general practitioner, with a mind trained to general observation, would be much less restricted in his views. The specialists, as adjutants to the physician, are most desirable, nay, indispensable; as separate and distinct practitioners they are dangerous.

THE PATRONS OF QUACKS.

"From a curious fact which has recently come to light at Chaux-de-Fonds, Turgénieff, the great novelist, did not put implicit confidence in the faculty; and, when medical men failed to relieve his sufferings, he sometimes applied to empirics. During the latter years of his life, he appears to have suffered much from a painful spinal complaint, for which he consulted many eminent physicians and tried innumerable remedies. According to *L'Impartial* of Chaux-de-Fonds, the police of that place took proceedings against a *medji*, or quack, whose supposed cures had won him a high reputation with the poor of the neighborhood; and among the man's papers was found a letter from Turgénieff, written at Bongival, near Paris, describing his disease, and asking for a prescription. This fact, if true, proves that the patrons of the secret practitioners of the healing art are not confined to the ignorant and obscure."

So says the *British Medical Journal*, and so eminently true is what it says that the subject admits of some elaboration.

When a very prominent divine was recently asked why it was that quacks and imposters were so very successful, he replied that it was owing to the *gullibility* of the human race. Barnum makes no secret of his success when he admits openly that he is the greatest old humbug of the age; and that by deceiving and fooling the people he has made his unparalleled popularity. In a recent advertisement of a quack medicine in one of our daily papers, we were surprised to see testimonials of merit from men holding the very highest rank in the army and navy of the United States, as well as from others equally distinguished in other professions. We must perforce presume

that these men authorized the use of their names, else the quack would hardly have had the temerity to publish them.

Human nature seems to lean to the mysterious, and will much more readily and cheerfully in many cases pin their faith to quack medicines whereof they know nothing, than to reputable and respectable practitioners.

THE HEALTH OF OUR CHILDREN.

One of our public schools was recently closed by order of the Board of Health, on the ground that it was a nuisance, prejudicial to the health of the children, on account of the filthy condition of its wells and serious defects in its ventilation. We are glad to record this fact, as a stride in the march of hygiene in our midst. A meeting of the school authorities was held to take action in the premises, and as they were about adjourning, another notice from the Board of Health was received. It required that the wells at another school house should be filled up and latrines substituted.

The chairman was greatly incensed at this new notice. "The Board of Health," he said, "has no right to dictate to this Board what it shall do and how it shall do it. We are created by the Legislature of the State of Pennsylvania." The notice was ignored.

We are very sorry to chronicle this latter fact, and we hope the day is not far distant when every city in the country will possess an official or a board of officials who will have the undoubted authority to enforce their sanitary recommendations. The question of public health is a matter of such great importance, that it should be removed far away from the contaminating and dependent influence of politics, and placed in an independent and intelligent position. The time will surely come—and why not hasten its coming?—when the law of the land, that is to say, of every State in the land, will require the examination of all public, yes, and of private buildings, by competent inspectors, upon whom will be conferred the requisite authority to enforce their sanitary admonitions. Let the profession move in this matter,

let our county societies memorialize the legislature on the subject, let the Keystone State inaugurate the sanitary reform, that, once started, will rapidly spread throughout the length and breadth of the land.

THE TRANSATLANTIC MEDICAL SERVICE.

An earnest effort is on foot to reform the condition of the medical service on the transatlantic steam vessels. At present, it is in a most unsatisfactory condition. The pay allowed to surgeons and assistant surgeons is so small that either no competent medical man will accept the position, or, should he do so, will not remain in it for any long time. What inducement is \$50 a month, combined with all the disagreeables of sea life, with no prospect of promotion, and not even a guarantee of permanence, to any capable physician? Yet that is about the maximum which these lines pay.

The result is that there is no stability in the medical service, and that it is usually supplied with young men who want a little change, or to see the incidents of traveling life.

What is needed is increased pay, which will be at least as high as that in the naval service, some certainty of retaining the position, and a proper examination of applicants.

There is a studied attempt on the part of some companies to debase the medical service. We have already called attention to the action of the Red Star Line in putting the surgeons in the second cabin. Probably they will send them to the steerage next!

We call upon our State Medical Societies and the American Medical Association to take action in this matter.

The efforts of Dr. J. A. Irwin (363 5th avenue, New York city) to bring about a reform of the service, should be supported by the profession on both sides of the Atlantic.

ACTION AND REACTION.

The great laws of nature are certainly immutable; with a precision that is marvellous, they cannot be altered one iota; cause and effect, action

and reaction, are ever present in all of nature's workings. To the careful reader of the medical periodicals of to-day, the reaction that always follows action is made clearly manifest. For some years past, and more particularly during the last two, the onward progress of our profession, both from a scientific as well as from a practical point of view, has been very rapid. But now comes the inevitable reaction; many of the fine-spun theories that have been advanced from time to time have been found unable to stand the test of experience, while also the originators in our ranks seem short of scientific breath, and are compelled to halt that they may recover "their wind." We are glad of this, for now we can have the time to carefully look into the true merits of the various plausible theories that scientific physicians have advanced, as well as the bold operations that have been done by the fearless surgeon. Thus we can separate the good from the bad—the wheat from the chaff—and having firmly settled truth on her pedestal, start off for another race of progress, from an even higher vantage ground than before.

LIMITING OUR WATER SUPPLY.

We are very sorry to learn that an effort is being made in this city to prevent what is called the excessive waste of water, and that this retrograde movement is receiving the sanction of some whose influence is very potent. We wish to be understood literally when we say that water cannot be wasted in a city. Of all disinfectants, purifiers, and preservatives of health, water stands pre-eminently in the front rank. Water and soap are two commodities that we cannot afford to dispense with, and of the two, water is by far the most essential. Far from limiting our water supply, it should be increased to an unlimited extent. What may seem to the uninitiated as waste, is not so at all. We grant that were all the people thoroughly acquainted with the dogmas of hygiene, so that they might intelligently use the water with a definite end in view, then could we accomplish much more with one gallon than we can to-day with five; but since this familiarity does not exist, then must we hold that a very

great abundance of water is necessary to accomplish these ends. Give us plenty of water, that we may waste it, if you like the word, and by so doing wash away from us decomposing organic debris that is breeding disease and death. We cannot have too much water. It is impossible.

POLICE SURGEONS.

More than eighteen months ago (August 26, 1882), we called attention, editorially, to the necessity of establishing a system of police surgeons in this city, and it now affords us pleasure to record that our suggestion has become a reality. The Mayor of Philadelphia has appointed a police surgeon (Dr. Morris S. French), who will in turn appoint a corps of assistants, one for each police district in the city, whose duty it will be to respond to all sick calls from each particular station house. It is proposed by the mayor to establish a system of physical examination of all applicants for positions on the police force, and the requirements which Dr. French has formulated are of a sufficiently stringent character to insure to this large city a very efficient police force, which is one of the most essential, and at the same time one of the most neglected features of our various municipal governments.

If our new mayor does nothing else during his administration, he will be entitled to the gratitude of all good citizens for having inaugurated a most praiseworthy and commendable reform in our police department.

NOTES AND COMMENTS.

Gangrenous Enteritis.

Before the Sheffield Medico-Chirurgical Society (*Brit. Med. Jour.*, February 16, 1884), Mr. C. Atkin read a paper on a case of gangrenous enteritis, making some remarks on enterectomy and enterography. The case was as follows: A painter, aged 30, was seized, four weeks before admission into the infirmary, with pain in the abdomen and continuous vomiting. The case was thought to be one of colic, and treated with enemata and purgatives; but no motion or flatus ever passed from him. When first seen at the infirmary, he was extremely emaciated. There was no hernia, nor

had he ever had one; no hardness along the colon or rectum; no stricture to be detected *per anum*. An enema could be distinctly heard with the stethoscope ascending and traversing the colon. A consultation being held, Mr. Favell determined to give the man a chance, however small, of being relieved by operation. Abdominal section was performed, and a loop of bowel was found to be gangrenous. As the man was moribund, it was decided to do no more, and the wound was closed. At the necropsy, next day, the bowels were first carefully examined *in situ*. No internal hernia, band, or twist, was to be found. They were then removed, and carefully examined inch by inch. No hard fæces, diverticula, or stricture, were visible. The heart was healthy; but his arteries were diseased, and the kidney showed commencing granular changes. Mr. Atkin then commented on the rarity of localized death of a loop of bowel arising *de novo*; and, after enumerating various causes, came to the conclusion that it was probably due to the state of the arteries, a branch probably becoming thrombosed. Allusion was made to the unusual duration of the case, and to the equivocal character that the first symptoms must have presented. The question of treatment was then gone into; and, it being assumed that abdominal section would have been performed had the case been seen earlier, the point what to do with the gangrenous bowel was discussed. Summaries of the cases of Kœberlé, Czerny, Schede, Sutton, Meusel, and Prati were read, and the different methods of suturing the bowel mentioned. The author then showed that stricture of the bowel never resulted, because union took place by the first intention; that the spur formed by the involution of the mucous coat was no impediment to the passage of fæcal contents; and that there was no danger of the sutures being burst open by flatus. The special clamps invented by Mr. Treves and Mr. Stanmore Bishop were mentioned, but were stated to be unnecessary, as several cases had done well without them, notably the recent one of Mr. Banks.

The Salicylates in Diphtheria.

The use of the salicylates is becoming very extended, for now Dr. C. R. Illingworth writes to the *Lancet*, February 16, 1884, recommending them in pneumonia and diphtheria. He says:

Some months ago I proposed the use of the salicylates in pneumonia, and at the same time I gave a very favorable opinion of their action. I wish now, through the medium of your valuable journal, not only to advocate their use in that

disease if possible more strongly than ever, but also to propose that they should be tried in diphtheria and true croup. I suggested this in a very cursory manner in the *British Medical Journal* last year ("Omega," June 23), but have never had an opportunity of testing their effects practically, although the theory I have formed as to the action of salicylates in general would seem to indicate the advisability of employing them.

In pneumonia I prescribe five- to ten-grain doses of the salicylate of soda every two hours, with twenty-minim doses of the aromatic spirits of ammonia for an adult. If the pulse should be very rapid and feeble, I add five minim doses of digitalis, and if there should be any delirium, ten-grain doses of the bromide of potassium. In children an acute congestion of the lungs is very rapidly thrown off with three-grain doses of the salicylate and five minims of ammonia every two hours. The compound spirits of ammonia is well known to have the property of reducing the fibrin-forming elements of the blood; but I am of opinion that the salicylate of soda prevents the formation of fibrin altogether, and in this way it may be said to be no more a specific for rheumatic fever than for pneumonia or diphtheria, or, indeed, for any other disease which is associated with or accompanied by the formation of fibrin. Whether it acts by altering the composition of the corpuscles, so as to prevent the formation of fibrinoplastic material, or upon the plasma, to prevent the development of fibrinogen, I am not prepared to say; but certain it is that there is the production by its use of a state of greater liquidity of the blood than ordinarily; and it is on this account that I think the mixture I have mentioned above will prove useful in the treatment of diphtheria and true croup, although in false or congestive croup I am inclined to place more confidence in astringents, such as steel and sulphuric acid.

Hydrargyri Tannicum Oxydulatum.

The *Med. News*, quoting from a foreign exchange, tells us that this preparation has been used in syphilis by Dr. Sigmund Lustgarten:

This salt is the tannate of the protoxide of mercury (hydrargyri tannicum oxydulatum), which contains fifty per cent. of mercury. It is a dull green powder, without odor or taste, and is only soluble when decomposed. Hydrochloric acid makes no sensible impression upon it, but very dilute alkalies, ammonia, solution of caustic potash, and the alkaline carbonates, reduce it in a short time to a sort of magna composed of very

small particles of metallic mercury. They are so minute that the greater part of them present, under the microscope, the phenomenon known as molecular movement. This process of reduction is produced under the influence of the alkaline reaction of the intestinal juices; whence it may be asked, if the absorption of the particles of mercury is produced in the same way in the intestines as on the skin by mercurial friction? The determination of this question has occupied the attention of Lustgarten for some time. He has now been able to demonstrate the rapidity of the absorption of mercury into the blood, having found mercury in the urine in twenty-four hours after its administration.

This new drug has been prescribed in two or three doses of gr. jss. every day, but in spite of this seemingly large dose no troubles of the stomach and bowels have been observed, nor the troubles usually seen when the ordinary mercurial preparations—calomel or corrosive sublimate—are administered; nor has stomatitis or salivation been observed, although the very large dose of grs. xc. has been given. On the contrary, in ten cases treated, up to this time, comprising every period of syphilis, and especially cases of relapse of a very rebellious nature, as syphilides with small papules and pustular syphilides, there was so rapid a regression of the lesions that Lustgarten does not hesitate to place the new drug by the side of the best mercurial preparations hitherto employed.

Spasmodic Contraction of Uterus or Placenta.

Dr. W. L'Hérenx Blenkarne reports this case in the *Brit. Med. Jour.*, March 1, 1884:

A primipara, aged about 30, had a fairly good time, the child being born naturally (but a dose or two of ergot having been given). On my finding that slight traction on the cord, telling the patient to blow on the back of her hand, and other simple means, failed to dislodge the placenta, I introduced my hand gradually into the vagina, and found that (apparently) the whole of the uterus was spasmodically contracted on the placenta, the os being somewhat contracted as well; so that I could only get two or three of my fingers into the cavity. There was no hæmorrhage, and the pulse was 60°. I did not, however, deem it advisable to wait very long; chloroform was therefore given by my partner, and the patient partially put under its influence. I was now enabled to introduce the whole of my hand into the uterus, and then found that the placenta was rotten and broken down; but it was not a

herent anywhere. There were still irregular contractions of the uterus, which caused me some difficulty in passing the whole of the placenta; but by degrees I did so, as I was anxious to remove it all without re-introducing my hand; this I effected at last, and thus saved the poor woman the discomfort of my removing it piecemeal. She made an excellent recovery, and at no time during the whole of the operation, or afterwards, did the pulse rise above its original standard of 60. It passed through my mind whether the ergot was accountable for this spasmodic contraction; but I am inclined to think that it was merely an idiosyncrasy of the patient, as I have repeatedly used ergot in my midwifery practice, and have never witnessed a similar untoward result.

Poisoning by Aconite.

Dr. Herbert W. Seager reports this case in the *Brit. Med. Jour.*, December 1, 1883:

One or two points in a case of poisoning by aconite may be of general interest. I saw the case for a neighboring practitioner, on November 11, about an hour after the poison had been taken. The patient was an hysterical woman, aged about 40. She had taken about three drachms of the linimentum aconiti *B. P.* When I first saw her, she was much prostrated; she did not answer questions, but was able to tell me that she had taken the poison herself, and to utter some short prayers. There were frequent general convulsions, rather violent. The face was much congested; the lips were red; the pupils much dilated; the sclerotic injected; the iris somewhat irregular in the external outline. The pulse was full, and somewhat irregular. Respiration was blowing, and rather rapid. A slimy tenacious mucus was expelled from the lips with almost every expiration. I gave her an emetic; but I believe there was no power of swallowing. The convulsions were easily repressed by a wet towel over the face and head; but this seemed to cause much depression. There was entire loss of sensibility of the skin. About a quarter of an hour after I saw her, the surface of the body became suddenly cold; the respiration and pulse ceased; but she was revived by a hot poultice on the epigastrium. The convulsions became less frequent as the poison gained ground; and she was speechless for about twenty minutes before her death, which occurred about an hour and three-quarters after the poison had been taken. At no time was the face blanched, or the lips bloodless; on the contrary, the lips became dark blue after death. A slight tremor of the lower lip was noticeable some moments after pulse

and respiration ceased. Artificial respiration was ineffectual.

The points to which I wish to call attention are: the convulsions; the inability to swallow; the dilatation of the pupils; the congestion of the face; the insensibility of the skin; and the reviving effect of the poultice over the epigastrium.

Inoculation of Tuberculosis.

Since the great interest which Koch's discoveries have thrown about this subject, all that pertains to its infectious or contagious properties must be read with interest. The Paris correspondent of the *British Medical Journal* tells us that at a recent meeting of the Académie de Médecine, M. Verneuil related the following history: In July, 1877, a house surgeon (interne) at the St. Eugénie Hospital, who performed all the post mortem examinations, one day noticed a papule at the base of the nail of his third finger. The apex presented a white spot, and a few drops of pus escaped from it. It was frequently cauterized, but the phalanges became attacked, and a cold abscess spread over the back of the hand. After three years' treatment, having failed to produce any improvement, M. Verneuil amputated the finger. The house surgeon was believed to be cured, and practiced in the provinces. Quite recently he has been again attacked by cold abscesses in the lumbar region, causing intense pain; during violent attacks of pain, the arms exhibit clonic convulsive movements. M. Verneuil has operated a second time. He is convinced that his patient became inoculated with tuberculosis when performing a necropsy. A similar misfortune happened to Laënnec. One day, when operating on a tuberculous patient, he slightly cut himself with a saw. A swelling appeared on the wounded part. Laënnec cauterized it with antimony-chloride. The swelling disappeared, but twenty years subsequently he died from tuberculosis.

A Foreign Body in the Bladder.

As aids to practice, all unusual cases are worthy of record, for by remembering them, we are oftentimes enabled to solve otherwise enigmatical cases. Such cases as the following, which Dr. Robert Storrs reports in the *Brit. Med. Jour.*, January 26, 1884, are both unusual and interesting:

"On January 9, 1884, I received a message to see Mrs. C., aged 64, the wife of a tradesman, and a very fairly intelligent woman. She was the mother of a large family, the eldest being more than thirty years of age. She was seen the same evening by Dr. McConnell, who is associated with

me in my practice. She presented to him all the usual symptoms of calculus. The following day she was seen by us together, when, with the sound, we clearly detected a foreign body in the bladder. We proceeded to dilate the urethra; and, in passing the finger through the urethra into the bladder, we detected a substance of a metallic nature. This we were able to extract by means of a long narrow pair of forceps passed by the side of the finger. It proved to be a hairpin of the ordinary size. This operation was followed by little or no incontinence of urine.

The chief interest in the case was how the hairpin got into the bladder, and the length of time it had in all probability been there. She appeared to have not the slightest knowledge as to how this entered her bladder, but she tells us that she has been conscious of the presence of something there since before the birth of her first child, more than thirty years ago.

Gangrene of Arm Following Injury to Thumb : Death.

Dr. Studdert, in the *Brit. Med. Jour.*, December, 1883, records the case of a man, aged fifty-three, who played a game of bowls, and on the following morning noticed a small blister at the extremity of the right thumb, which, he thought, must have been occasioned in some way during the progress of the game. Two days after the injury he consulted Dr. Studdert. There was then a small punctured wound at the top of the thumb, from which oozed an ichorous discharge. There was no inflammation of the arm, nor any constitutional disturbance. On the fourth day the patient felt ill, and spent a sleepless night. On the fifth day the arm became enormously œdematous, and there was severe pain. The temperature was 101.8° F. Free incisions were made in the arm, after which the limb went down; the temperature fell to 99°, and all pain had ceased. On the sixth day the swelling had returned somewhat, and by evening the limb had become gangrenous. Amputation at the shoulder-joint was decided against, and the patient died during the night.

A New Method of Removing Nasal Polypi.

In the *Canada Medical Record*, February, 1884, Dr. William Ralph Bell says :

"I take the liberty of bringing the mode of treatment before the notice of your readers, which I have practiced with the very best results in several cases. It obviates any trouble from hemorrhage, which is frequently the case when the forceps or hook is used; it is painless and very

simple. I get my patient to blow strongly through the affected nostril, closing the other with his finger. The polypus will be brought down so that it can be easily seen through the external nares; then with my hypodermic syringe charged with a solution of tannic acid in water (of the strength of twenty grains to the fluid drachm), I pierce the polypus with the needle, and inject ten, fifteen, or twenty minims of solution, according to size of tumor. In a few days the polypus shrivels and dries up (tanned); it comes away without any trouble or pain, and looks like a clot of dry blood, my patients usually removing it by blowing the nose or by their fingers. In only one case, that of an old lady, had I occasion to remove it myself, and in her case I think she was afraid to do so, for when I seized it with dressing forceps, I required to make no traction to bring it away."

Transplantation of Healthy Skin in Lupus.

Hahn (*Monatsh. für Prakt. Derm.*, No. 9, 1883,) has scraped out lupus-tissue and grafted transplanted healthy skin to the fresh wound in five cases with good results. The patients were anesthetized, and, after the scraping was finished and the bleeding arrested (which sometimes did not occur until after several hours), the whole wound was covered by portions of skin about half a centimètre long and a quarter centimètre broad, the portions consisting only of cutis and epidermis. Under iodoform bandage, complete union of the transplanted portions occurred mostly in from five to eight days. A year had elapsed since the treatment of the first case, the cure being so far permanent, and no relapse having occurred.

Hospital Entertainments.

A strange sort of festivity, says *Truth*, took place recently at the Hospital St. Louis, at Paris. A comic opera, written and composed by the young surgeons attached to the establishment, was performed for the amusement of the patients. Fifty years ago, Charles Fourier, the celebrated philosopher, wrote: "One day medical science will endeavor to overcome the sufferings of patients by amusing their minds; hospitals will be filled with flowers, and music and plays will be performed there." And yet it was currently reported that Fourier was mad.

Bromine in Diphtheria.

Bromine is strongly recommended by Dr. Schiltz (*Pharm. Central.*, February 14, p. 71) in the treatment of diphtheria. One form in which he uses it

is as a solution prepared thus: chlorine water, 30 parts; distilled water, 150 parts; and bromide of potassium, 3 parts. The bromine separated by the chlorine from the bromide of potassium, remains dissolved in an excess of the latter, like iodine in potassium iodide. The chlorine water of the German Pharmacopœia is not so strong as that of the British Pharmacopœia.

Treatment of Chronic Adenitis.

An exchange publishes the following formulæ:

1. Lard, 30 grammes (say $\frac{3}{4}$); ammonium chloride, 5 grammes ($\frac{3}{4}$ ss.); and camphor, 2 grammes ($\frac{3}{4}$ ss.). Mix. To be applied night and morning.

2. Potassium iodide, 1 gramme (gr. 15); distilled water, 5 grammes ($\frac{3}{4}$ iss); extract of hemlock, 2 grammes ($\frac{3}{4}$ ss.); lard, or vaseline, 30 grammes ($\frac{3}{4}$ j.). Mix.

3. Calomel and acetate of lead, of each 3 grammes (gr. 45); lard, 20 grammes ($\frac{3}{4}$ v.); camphor, 5 decigrammes (gr. 8). Mix.

CORRESPONDENCE.

Dr. Rezin Thompson's Formula.

EDS. MED. AND SURG. REPORTER:

Here is Rezin Thompson's formulary:

R. Syr. rhei, $\frac{3}{4}$ iv.; piperin, sodæ bicarb., $\frac{1}{2}$ aa gr. x.; olei sassafras, gtt. xx. Rub all together in a mortar and add saturated tinct. of valerian, $\frac{3}{4}$ ij.; mix and rub again. Sig.: For an adult a teaspoonful every two hours until the disease (typhoid) is checked. Or thus: Rhei pulv., $\frac{3}{4}$ ss.; piperin, zinci valerianatis, ext. valerian, soda bicarb., of each grs. x; ol. sassafras, gtt. xxx.; pulv. acacia, q. s.; misce et div. in. pil. no. xxx. Sig.: One every two hours, as with the first.

He claimed that the above would actually abort typhoid fever, if begun with in time. I have never tried it. He believed that the valerian played an important part.

B. F. RECORDS, M D.

Displacement of Colon.

EDS. MED. AND SURG. REPORTER:—

By reading the statement in the REPORTER not long since, that displacement either of the ascending or descending colon is practically impossible, I am prompted to report to you a case in which the ascending colon was displaced.

The autopsy was made with the object of ascertaining the origin of fatal hemorrhage. This was found to be from a branch of the gastric, opening into an ulcer in the posterior wall of the stomach, about three-quarters of an inch from the lesser curvature at its centre.

From the cæcum the colon extended in a curve, its convexity towards the left inguinal region to

the splenic flexure. The stomach lay close to the colon, parallel with it in general direction, its pyloric end being very low, and its lesser curvature apparently stretched. The great omentum was very small, not sufficing to cover the colon.

I am sorry I cannot give you a good description of the conditions found, the examination having been hurriedly made, with no other object but the one mentioned.

Hilliard, O., March 24.

Croton-Chloral Hydrate in Whooping-cough.

EDS. MED. AND SURG. REPORTER:—

I have been using this remedy for the past eight years, in the treatment of whooping-cough, with the most gratifying results. In ninety-five per cent. of the cases in which I have used it, the disease was cured in from six to twelve days. During the past five years we have had two epidemics of pertussis in this town, which gave me ample opportunity of testing the merits of croton-chloral in persons of almost all ages; from infants under eight months, to persons of the age of fifty-five years. I found it act equally well, no matter what the age was. It must be given in full doses, properly dissolved, and every three hours. My method of prescribing it is as follows: For a child from eight to ten years of age:

R. Croton-chloral hyd., $\frac{3}{4}$ iiss.
Aque bullientis ad., $\frac{3}{4}$ viij.

M. Sig.— $\frac{3}{4}$ ss every three hours, night and day.

The above dose, of course, should be increased or lessened, according to the strength and age of the patient. I do not use anything to cover the taste of the remedy, nor do I use anything to render it more soluble, experience having taught me that the best results were obtained when the remedy was given as above described. Croton-chloral has proved as sure a specific in my hands, in whooping-cough, as quinine has in intermittents. Let it be constantly borne in mind, that to get the beneficial effects of this drug, it must be given in full doses, properly dissolved, and every three hours.

Answers to "Medica."

EDS. MED. AND SURG. REPORTER:—

Under the head of "Gynecological Queries," in No. 8 (February 23), page 256, "Medica" inquires for suggestions in a case. Having had a patient for the last year and a half of somewhat similar character, who has given me much trouble and thrown defiance into my face worse than most anything I have ever found, I sent her into the country to free her from all care, when her friends went into the woods and obtained the root of the cypripedium, or moccasin plant, which she used in an infusion, and began to feel the good effects immediately. This was last fall. She has now come home quite another woman, but says she cannot get along without her remedy.

I never like to give up, but I must own that this simple remedy, which I have not used for thirty years, has discounted my pharmacopœia, gynecological applications, time, and everything

else. I rarely get a case like this, which gives me such a good chance to try my skill, and that for a considerable period, till I am at my wits' end. Yet it is evident enough that this simple little plant does hold some control over her nerves, which keeps up her appetite, keeps off headache and the aches through her body, regulates her turns, and controls the uterine conditions beyond anything I could suggest. She has had one child, and now has "ulceration," with leucorrhœa, all of which is thoroughly rebellious. I have seen only two or three cases of such "ulceration," and hope to see no more. If I do, I shall use cypridium, to see what it will do. I am persuaded that the "ulceration" and leucorrhœa still exist in the case, though I have not examined her for many months. So bad was it, or the irritation from it, that the woman was sure to be sick if she attempted even a short walk. This has passed away, so that she is on her feet a great deal, doing her work and taking long walks frequently.

So far as I can judge, this great benefit to her is all from the cypridium. When she first got into the country, she continued to run down for two weeks, till this remedy was taken; and now, whenever she leaves it off she begins to lapse in her feelings. Practically cured with the remedy, she may not be cured without it, and so have to take it—as Dr. Cole said they do tobacco who use it—"eternally." However, I am glad for something which helps my case so much more than anything else which I could find. All external treatment has been abandoned since last summer.

Boston, Mass.

NEWS AND MISCELLANY.

Kentucky State Sanitary Council,

Held at Bardstown, Nelson county, March 26 and 27, 1884, under the auspices of the State Board of Health.

The Kentucky State Sanitary Council held its third semi-annual session at Bardstown, Nelson county, on Wednesday and Thursday, March 26 and 27.

The Council was called to order for the first session at 7 p. m., at the county court house, by Dr. J. A. Dixon, of Burksville.

Dr. Alexander Crawford, in behalf of the resident physicians and citizens of Nelson county, delivered an address of welcome, which was responded to in behalf of the visiting delegates by the President, Dr. J. A. Dixon, who spoke as follows:

"Ladies and Gentlemen of Bardstown and Nelson County: The fame of Kentucky hospitality is world-wide, and the culture, refinement, and generosity of the citizens of Nelson county is proverbial. Your welcome this evening does not detract from the well-earned reputation of which all Kentuckians love to boast. We fully appreciate the welcome we meet at your hands, and enter upon the proceedings of this council with our zeal and enthusiasm increased by the interest manifested in this work of sanitary regulation by your community.

"Public health is public wealth, and the first great duty of the state is to look to the health of the people. The importance of the subject is greater than all others, because it embraces all others. Political economy estimates the money value of human life, and by these estimates we are able to calculate the loss to society, the state, and the nation, by the untimely deaths that occur from preventable causes. Small-pox, yellow fever, or any other contagious or infectious disease prevailing in a community, causes inestimable loss to the commercial interests, as well as greatly increased individual expense. The loss to Philadelphia in 1871 and 1872 from the outbreak and epidemic of small-pox, which resulted in the reporting of 23,000 cases, has been estimated at \$28,000,000. This could have been prevented by efficient sanitary organization. Yet the ignorant say no good can come of these sanitary organizations.

"The message of Gov. Knott contained not one word in reference to the health of the people over whom he rules. All the avocations of life at the present time have their organizations, and to-day political conventions are being held to give shape to our national affairs. The workmen demand through their organizations redress of their real or fancied wrongs. Our best men are organizing in order to work out the great problem of public education, and we, as public-spirited citizens, meet to discuss ways and means to alleviate the pain and prevent the diseases to which our fellow-men are exposed. The time has come when we must protect our homes and avoid the positive disgrace of being sick. This is what we hope to accomplish.

"In closing these very brief remarks, allow me to hope that when disease and pestilence stalk abroad in the land, your beautiful city and good people shall escape, because you have the blood of purity sprinkled upon your door-posts."

The first regular paper of the session was read by Dr. Dudley S. Reynolds, of Louisville, on the subject of "Foods as Causes of Certain Classes of Disease."

"As an article of diet," said he, "sugar is classed high in the list of force-producing agents. It is not as widely known as it should be that the term sugar in this connection is intended to indicate saccharose, or cane sugar, which has been freed from glucose, naturally present in it in its crude state, or in the expressed juice of the cane. It is unnecessary to go into the details of the process for separating the glucose from the crystallizable saccharose, but the latter and not the former is valuable as an article of diet. The glucose naturally present in the juice of the cane is a comparatively harmless form of that substance. Likewise the expressed juice of what is commonly called sorghum. Either of these, however, on being subjected to a high temperature, which is sometimes done to improve the color, loses greatly in value, and then becomes noxious to the system. Even saccharose in its purest form, mixed with water, may be converted into glucose of a highly irritating character at a temperature of 320° F. When saccharose, in combination with free acids, is heated to 212° F., new compounds are formed called saccharides. Some of these have the constitution of ethers, whilst a combination of fruit

or vegetable acids with saccharose converts the latter into glucose at a much lower temperature. Concentrated acids, such as are found in the stems of the so-called pie plant, decompose saccharose even without the aid of heat.

"Laevulose is the name given to the sugar of fruits and of honey. In our ripe fruits this is transformed into glucose. In cooking fruits, the laevulose and the fluid acids combine to form powerful ferments, which resist the action of the gastric juice, and which are composed of very fine cells that find their way along with the food into general circulation. As soon as they enter the blood-current, the white blood-cells begin to exhibit abnormal activity of movement. Presently, the lymph-channels are observed to be unduly full. In time, the lymph-glands enlarge; later, the lymph-channels in mucous membranes, especially the naso-pharyngeal, become so engorged as to rupture, and exudation of lymph begins. When this occurs in the nasal or pharyngeal membrane, the patient considers he has catarrh; consults a physician, who tells him it is due to a series of colds he has contracted; and he is treated by all the various means in popular use for the relief of an imaginary bad cold. Of course the patient never gets better in consequence of the treatment, and he is fortunate if he is not made worse. Vegetarians who are gradually led into the habit of eating cooked fruits, finally abandon all other diet. This is attended by progressively increasing prostration and engorgement of the lymph-channels and enlargement of the lymph-glands, including the tonsils.

"It has been so often observed that the children of the poor enjoy better health than those of well-to-do people, that it has been often advised by high medical authority that it were better children should cultivate acquaintance with the pigs than to remain too much indoors. It must not be supposed for one moment, however, that friendly relations with the pigs has anything to do with the superior health of the laboring man's children. Observant people know the diet of the laboring man's family is necessarily plain and simple. In the country, the working man can afford nothing better than milk and butter, plain meats and gravies, and common vegetables. Upon this diet his children fatten and grow, while the children of those who can afford candy, preserves, pies, and fruit sauces, suffer glandular enlargements and all those symptoms which attend the so-called strumous diathesis."

(To be continued.)

State Medical Society of Arkansas.

The ninth annual session will be held at Little Rock, on Wednesday, April 30th, Thursday, May 1st, and Friday, May 2d, 1884, commencing at 10 a. m. on Wednesday.

The members are earnestly urged to be present, and to induce others to join in the work of advancing legitimate medicine.

Each county or municipal society shall be entitled to one delegate for every five members, and one for a fraction over five.

"The several committees shall report annually, through their chairmen respectively, upon the

specific subjects to which they have been appointed. It shall be the duty of each committee to make a full and complete report to the society of all matters, business, etc., that properly comes before or presents itself to them upon each particular branch or section." Art. ix, Sec. 2, Constitution.

The subjoined are the committees to report at the meeting:

Committee on Medical Education: G. W. Hudson, chairman, Camden, Ark.; M. C. Weaver, S. M. Carrigan, J. R. Brewer, R. B. King, A. J. Pulliam, J. J. Robertson, L. Kirbey, E. A. Baxter.

Committee on Practice of Medicine: T. D. Nichols, chairman, Paris, Ark.; D. H. Stayton, J. F. Blackburn, T. B. Hodges, C. L. Kirksey, L. Holmes, A. J. Brewer, J. A. Dibrell, sr., W. W. Bailey, J. W. Pinson, D. S. Williams.

Committee on Surgery: J. E. Bennett, chairman, Fort Smith, Ark.; J. R. Dale, W. B. Lawrence, A. A. Horner, D. A. Linthicum, J. P. Mitchell, J. M. Jelks, W. M. Lawrence, T. W. Hurley.

Committee on Gynecology: J. T. Jelks, chairman, Hot Springs, Ark.; H. H. Turner, L. R. Stark, D. C. Ewing, W. A. Sayle, J. B. Cummings, D. Christian, J. G. Eberle, R. S. Wallis.

Committee on Medical Legislation: F. G. McGavock, chairman, McGavock, Ark.; J. H. Southall, G. B. Malone, L. E. Bennett, W. J. Watkins, R. N. Ross, D. C. Carroll, S. L. Vaughan, J. B. Thompson.

Committee on Necrology: Isaac Fulsom, chairman; D. S. Mills, S. W. Allen, C. E. Nash, R. C. Wallis, R. M. Wilson, T. M. Pinson, J. W. Hayes, J. D. Jordan.

Board of Visitors to the Medical Department of the Arkansas Industrial University: Z. Orto, chairman; W. W. Hipolite, J. C. Wallis, J. E. Bennett, A. G. Henderson.

Committee on State Medicine: R. C. Pruitt, chairman, Osceola, Ark.

Special Committees on County and Municipal Societies: L. P. Gibson, chairman.

It is especially urged that each chairman will exert himself to have a full and complete report from the respective committees; and a paper by any member on the science of medicine and surgery, or its co-ordinate branches, will add greatly to the interest of the meeting. Any member who may desire to present a paper, will confer a favor by sending immediately the title of the same to the Secretary, so that a full programme may be prepared and sent to the members at least two weeks before the meeting, thus enabling them to prepare for the work that is to be done.

Secretaries of local societies are requested to forward as soon as appointed a list of the delegates. Arrangements will be made by which reduced rates can be obtained by all who may attend the meeting. Hence, those who intend to be present, whether already members or not, will please notify the Secretary at once, so that a certificate may be forwarded them in order to obtain the reduction.

L. P. GIBSON, M. D., Secretary,
Little Rock, Arkansas.

Weston's Walk.

We noted some time since the great feat of pedestrianism that Weston had undertaken in

England. On Saturday, March 15, he completed his walk, amid the enthusiastic applause of a crowded and representative assembly of Englishmen and Americans. The stage was occupied by an influential company, among whom were at least a score of medical men, and an equal number of clergymen. During the last week, Weston walked regularly every day from 7 in the morning till half-past 9 at night, with an interval of rest from 5 p. m. till 7.30 p. m. Notwithstanding the loss of sleep during the last two nights, from the excitement on approaching the close of his undertaking, during the week Weston was quite free from the drowsiness which had been so overpowering nearly every morning for the first three-quarters of his tour. He completed 45 years of age with the termination of his walk, when he was found to weigh 129 pounds, a loss of exactly 8 pounds since he started from London four months before. A careful examination proved him to be in excellent health, and quite fit to set out on a task of equal magnitude the following day. So healthy and vigorous was he, mentally and physically, though the last but one mile had been the fastest of any, having been done in 9 min. 17 sec., that, after the presentation of addresses of congratulation from the Councils of the Society for the Study and Cure of Inebriety, and the Medical Temperance Association, and a special vote of thanks spoken to by Dr. Hare, President of the Metropolitan Counties Branch of the British Medical Association, Weston made a long and spirited reply. The medical framer of the conditions of the walk testified that all these conditions had been honorably observed, and that, on several occasions, more than the stipulated daily distance of 50 miles had been covered. Few walks have ever been begun, carried on, and ended under greater difficulties. The sore on the pedestrian's heel, which was a continual source of irritation for half the time, would have prevented most men from walking five miles a day; while Weston, from repeated pecuniary disappointments, was weighted with the depression of spirits consequent on a regularly increasing deficit, amounting at last to about \$3500. To these must be added the fact that, contrary to medical remonstrance, he started while out of condition, and suffering from acute catarrh. Weston was accompanied throughout by reliable judges and referees, and the whole journey was done in the public eye, so that there can be no doubt as to the accuracy of the record. The feat thus successfully accomplished is unique. Endowed with no remarkable muscular power, Weston has owed his success in great part to the mode of living he adopted, the chief feature of which was total abstinence from all intoxicating drinks. Whatever may be attempted and executed in future, this remarkable and original experiment has demonstrated that a resort to intoxicating stimulants is not essential to the accomplishment of severe and long-continued bodily exertion. We recognize, with peculiar pleasure, the constant support which Weston has received, during his performance, from the medical profession.

—The bill to regulate medical practice in Maryland has been killed, the *Med. Record*, April 5, 1884, tells us.

Official List of Changes of Stations and Duties of Medical Officers of the United States Marine Hospital Service, January 1, 1884, to March 31, 1884.

Fessenden, C. S. D., surgeon. To proceed to Cairo, Illinois, and Memphis, Tennessee, as inspector, March 5, 1884.

Purviance, George, surgeon. Granted leave of absence for thirty days, February 16, 1884.

Smith, Henry, surgeon. To rejoin his station at Norfolk, Virginia, March 7, 1884.

Irvin, Fairfax, passed assistant surgeon. Relieved from duty at Norfolk, Virginia; to assume charge of Cape Charles Quarantine Station, March 7, 1884.

Carmichael, D. A., assistant surgeon. To report to Surgeon Purviance for examination for promotion, March 5, 1884.

Armstrong, S. T., assistant surgeon. To report to Surgeon Fessenden for examination for promotion, March 5, 1884.

Bennett, P. H., assistant surgeon. Leave of absence extended ten days, January 18, 1884.

Ames, R. P. M., assistant surgeon. Detailed for temporary duty on relief boat, Ohio River flood sufferers, February 16 and March 1, 1884.

Devan, S. C., assistant surgeon. Upon expiration of leave of absence to proceed to St. Louis, Missouri, for temporary duty, February 6, 1884.

Kalloch, P. C., assistant surgeon. To proceed to Charleston, South Carolina, for temporary duty, February 1, 1884.

Bevan, A. D., assistant surgeon. Granted leave of absence for seven days, March 13, 1884.

Wasdin, Eugene, assistant surgeon. Granted leave of absence for fifteen days, March 4, 1884.

Battle, K. P., assistant surgeon. To proceed to New York, N. Y., for temporary duty, February 4, 1884.

RESIGNATION.

Cooke, H. B., passed assistant surgeon. Resignation accepted by the Secretary of the Treasury, to take effect February 5, 1884, January 31, 1884.

APPOINTMENT.

Battle, Kemp P., M. D., of North Carolina, having passed the examination required by the Regulations, was appointed an assistant surgeon by the Secretary of the Treasury, February 2, 1884.

PROMOTIONS.

Carmichael, D. A., passed assistant surgeon. Promoted and appointed passed assistant surgeon by the Secretary of the Treasury, from March 1, 1884, March 18, 1884.

Armstrong, S. T., passed assistant surgeon. Promoted and appointed passed assistant surgeon by the Secretary of the Treasury, from April 1, 1884, March 28, 1884.

Value of Ingenious Splints.

Mr. Hutchinson, of London, said in a recent lecture, that as a commentary on the futility of inventing complicated splints and apparatus for fixing fractured limbs, none of which have ever received general approval, he might refer to an ingenious instrument devised by Dr. Gordon, of Belfast, after long-continued anatomical study of Colles' fractures. This, which was intended for

general use among surgeons, is figured, says Mr. Hutchinson, in a text-book by a leading surgeon, *upside down*; and assuming from this that even the author of the work is practically unacquainted with the splint, although he writes about it, what chance is there of its ever being universally adopted?

Not only Colles', but all fractures, are most successfully treated by extension, which can readily be applied through the agency of a simple straight splint. Very thick pads should be fitted to the splint, and in ordering from instrument-makers it is necessary to insist on this especially, particularly with regard to splints for treatment of fractured femur. Finally, on this subject of splints, Mr. Hutchinson declared that he had seen many more instances of bad union follow the use of modern improved apparatus, than ever were witnessed under the old plan of treatment of fractures by the straight splint.

Medico-Chirurgical College.

The third annual commencement of the Medico-Chirurgical College was held April 2, at Association Hall. Choice selections of music were given by Professor Fehling's orchestra.

The members of the Faculty and the graduates occupied seats upon the platform, clad in college caps and gowns. The exercises were opened by Rev. Wayland Hoyt, D. D., who made an impressive prayer, which was followed by an appropriate piece of music. Professor George P. Oliver, A. M., M. D., the President of the Faculty, then conferred the degree of Doctor in Medicine upon the following-named graduates:

John W. Hoskinson, Albert Kulb, and Edward F. Manger, all of Pennsylvania, and Dr. Constantine de Navosselsky, of Russia. The first and last-named were awarded prizes by Professor Abraham S. Gerhard.

Then followed an address by Professor George E. Stubbs, and the valedictory address by J. W. Hoskinson. The benediction was pronounced by Rev. Charles G. Fisher. At the conclusion of the exercises the floral offerings from friends were presented to the graduates.

Fresh Paint.

In the *Lancet* we read: The current belief among householders that the smell of fresh lead paint is noxious is founded on pretty general experience, but is opposed by the belief, equally current among chemists, that lead compounds are not volatile. A fact recently brought to our notice seems to support the domestic theory. The basis of the useful and popular luminous paint is known to be sulphide of calcium. Now, this compound, when unprotected by varnish, glass, or some other impervious substance, is slowly acted on by the acids of the air, and sulphuretted hydrogen is evolved, which blackens lead paint. This is well known, and can easily be avoided by proper protection of the paint. But the curious thing is that unprotected luminous paint is found to be perceptibly blackened by the fumes from fresh lead paint. There seems to be only one possible explanation of this—namely,

that a surface freshly covered with lead paint does actually emit some volatile compound of lead. We believe that many physicians could confirm this view from their own observations in regard to newly painted houses.

Medical Supply and Demand.

An exchange says statistics show that among 1,000 doctors the number of deaths annually ranges between 15 and 25. At this rate the number of deaths annually among the 90,000 medical men of this country would be on an average 1,800. Among the 14,000 physicians of Austro-Hungary, the annual death-rate is said to be about 320. If the same ratio existed in this country, the number of deaths annually would be slightly over 2,000. Probably the actual figure is not far from 1,800. On the other hand, the number of medical graduates in 1882-3 was 3,979, or nearly 4,000, and more than double the estimated number of deaths. Account must be taken of the number of physicians who annually retire from practice, and on the other hand of the number of graduates who never enter the practice of medicine. The annual increase of population is probably over a million.

The Association of American Medical Editors.

The annual meeting of the Association of American Medical Editors will be held in Washington, May the 5th, at 8 p. m., in Medical Hall, southeast corner of Sixth and F streets.

The annual address will be delivered by President Leartus Connor, M. D., on "The American Medical Journal of the Future, as Indicated by the History of American Medical Journals in the Past."

Dr. N. S. Davis will open the discussion on "How Far Can Legislation Aid in Elevating the Standard of Medical Education in this Country?" in which Dr. A. B. Palmer, Dr. Henry O. Marcy, Dr. L. S. McMurtry, Dr. C. H. Hughes, Dr. Frank Woodbury, Dr. William Brodie, Dr. A. N. Bell, Dr. William B. Atkinson, Dr. W. C. Wile, Dr. W. R. D. Blackwood, Dr. Henry Leffmann, and Dr. Deering J. Roberts will take part.

Philadelphia County Medical Society—A Correction.

Our contemporary the *New York Medical Record*, in its issue of April 5, says:

"At a largely attended meeting of the Philadelphia County Medical Society, April 2, a proposed amendment to the constitution, permitting the admission of female physicians to membership, was defeated by a vote of 79 yeas and 48 nays, it requiring a two-thirds vote for the passage of the amendment."

It is just the reverse. The amendment that was defeated provided for the insertion of the word *male* after the word *regular* in the by-laws, which would have made the clause read, "The Society shall consist of regular *male* physicians." This amendment was defeated, which has the effect of still permitting women to knock at the doors of the County Society for admission.

The Garfield Memorial Hospital.

The Board of Directors hope to open this hospital in May. The medical and surgical staff has been formed as follows:

Consulting Surgeons.—Drs. Fred. May and N. S. Lincoln.

Consulting Physicians.—Drs. W. W. Johnston, J. Taber Johnson, and A. Y. P. Garnett.

Attending Surgeons.—Drs. C. E. Hagner and J. H. W. Lovejoy.

Ophthalmologist and Otologist.—Dr. Swan M. Burnett.

Our New Police Force.

Mayor Smith has determined to follow the rule that has for years been in practice in New York, Boston, Pittsburgh, Chicago, and other large cities, of requiring that the police shall be of sound mind and body. He requires that a thorough examination be made of each applicant and member of the force.

The Mayor also intends to remodel our police force, and introduce some of the features in relation to the medical department that have been found so successful in other cities.

American Medical Association and Railroads.

We are authorized by the Chairman of the Committee of Arrangements, at Washington, to state that arrangements are being made with all railroads reaching Washington from every section of the country, looking to a reduction of fare for delegates to the Association, which meets in that city on the first Tuesday in May next. Those who desire further information upon this subject can apply to Dr. D. W. Prentiss, of Washington, D. C.

The Quintessence of Listerism.

The Vienna correspondent of the *Gazzetta degli Ospitali* was recently invited to a laparotomy in Professor Billroth's clinic in the following note: "Dr. — is hereby invited to the operation of —, which is to take place —. It is understood that Dr. — undertakes not to visit the same day, before the operation, sick rooms, dissection rooms, or other places in the Pathological Institute, and not to wear clothes which he may be in the habit of wearing in visiting these places."

Items.

—Colonel George L. Perkins, of Norwich, Conn., who is 96 years old, said in a recent interview: "I have buried six family physicians, and still live."

—The Missouri State Medical Association will hold its twenty-sixth annual session at Sedalia, on Monday, May 5, 1884, and the two following days.

—A bill to regulate the practice of medicine and the sale of medicines in Utah was passed by the Legislature, but vetoed by the Governor, at the solicitation, as we are informed, of certain patent-medicine men.

—An effort to abolish gradually the liquor traffic, by selling licenses annually at auction, increas-

ing their price each year \$100, and decreasing the number annually sold, has been commenced in this city.

—The Rumford Chemical Works gained another suit last month in an action against some of the imitators of their yeast powder. A perpetual injunction was granted against L. E. Wetter and eighteen others in the case.

OBITUARY NOTICE.

DR. JONATHAN A. WHITE.

Dr. Jonathan A. White, of No. 672 Lafayette avenue, Brooklyn, died March 30th, at Macon, Ga. He was born in Baldwinsville, Mass., in 1830, and studied medicine at Woodstock, Vt. He entered upon the practice of his profession in Brooklyn, and afterward at Baldwinsville. He served as an army surgeon during the war, and saw hospital service in New Orleans and Vicksburg. After the war he returned to Brooklyn, and for twelve years he was medical examiner for the Metroplitan Life Insurance Company. Heart disease caused his death. Dr. White was a widower, and he left no children.

QUERIES AND REPLIES.

EDS. MED. AND SURG. REP.—

Please tell me what change is made in whisky by burning to render it medicinal. SUBSCRIBER.

Ans.—We never heard of burning whisky for medicinal purposes, but suppose it would drive off some of the volatile oils and weaken it somewhat. Brandy is frequently burned, even when used simply as a beverage.

Dr. D. C., of N. Y.—You will find the formula for the original "Basham's mixture," also for the improved Basham's mixture prescribed by Dr. Da Costa, in Napheys' *Medical Therapeutics*, seventh edition.

Dr. D. N. P., of N. C.—In Seguin's fever-thermometer you read upwards or downwards from the normal point; in others the scale is ascending. Your inquiry is not quite clear, but we believe this answers it.

Dr. K. F. P., of Conn.—We do not think that abnormalities of growth are signs of atavism; their origin is generally traceable to fetal conditions.

Physiologist, Pa.—We do not desire any legislation whatever on vivisection, and can see no occasion for it in this commonwealth.

MARRIAGES.

PETTY—MILLS.—At Antigo, Wisconsin, Saturday, February 16, 1884, Dr. J. C. Petty and Hattie M. Mills.

MARKLEY—KNIGHT.—At the residence of the bride's parents, March 12, 1884, Dr. Paul H. Markley, of Hatboro, Pa., and Miss Emma J. Knight, of Holland, Pa.

DEATHS.

YOST.—At Loganville, York county, Pa., of cerebro-spinal meningitis, George Leroy, son of Dr. George P. and Olivia V. Yost, in his fifth year.

SAUNDERS.—In Cincinnati, Ohio, at 11 o'clock p. m., Sunday, March 16, 1884, Richard Westrop Saunders, M. D., Vice Consul to Italy.

LECTURE.

ATROPHIC NASAL CATARRH.

A CLINICAL LECTURE DELIVERED TO THE POST-GRADUATE CLASS AT THE UNIVERSITY OF PENNSYLVANIA.

BY DR. CARL SEILER,

Instructor in Laryngology and Lecturer on Diseases of the Throat, Nose, etc.

GENTLEMEN: There is a class of cases of nasal disease which has as yet received very little attention by writers and practitioners, and which, although not as commonly met with as other varieties, yet is frequent enough to merit our consideration. This class of cases is characterized chiefly by a peculiar penetrating odor emitted by the nasal cavities, which is sometimes so strong as to make the presence of the patient in a room almost unendurable. On account of this odor, the disease has been termed "ozæna" by the older writers, a term which is incorrect and misleading, as it merely implies one of the symptoms of the affection, viz.: the bad odor, and this may be present in other forms of nasal disease.

It will be best for you to examine this boy yourselves, to appreciate the pathological changes which have taken place in his nasal cavities, before we can discuss the treatment suited to this affection. You see that the posterior wall of the pharynx is extremely dry and shiny, without any elevation or enlargement of the follicles and glands which we are accustomed to see in the ordinary form of nasal catarrh. The rhinoscope shows the naso-pharyngeal cavity to be lined with large seabs of hardened secretion, so that very lit-

tle can be seen of the mucous membrane. The posterior ends of the turbinated bones, as they project into the openings of the posterior nares, are thin, and where the mucous membrane can be seen through the coating of inspissated secretion, it appears pale in color. The same condition of things is seen in the anterior nasal chambers, which are occluded by large plugs of hardened secretion, and appear unusually wide, because the lower turbinated bone seems to be absent. Careful and persistent questioning fails to reveal any specific taint in the patient, and in fact he is almost too young to have acquired syphilis, being only fourteen years of age. What he complains of is obstruction of the nose, dryness of the pharynx, loss of sense of smell, and the stench from his nose.

What is the cause of this accumulation and inspissation of secretion, which, by becoming putrefied, produces the odor? The answer to this question is the key-note to the pathology of the disease, and also the guide in the rational treatment of the disease.

After thoroughly cleansing the nasal cavities, and removing the plugs of hardened mucus with copious streams of an alkaline solution, we see on inspection that the mucous membrane throughout the nasal cavities is in a state of atrophy, which affecting the turbinated bones also, has materially reduced their size, so that you can easily see the pharyngeal wall through the anterior nasal cavities. This atrophy affects chiefly the serous glands, which, as you know, are quite numerous in the nasal mucous membrane, and which, by their secretion when in a normal condition, makes the mucus thin and watery, so that

it can easily be removed by blowing the nose; when however, as in the case before us, they are atrophied, and their secretion reduced to a minimum, the mucus secreted by the mucous glands remains viscid, and clings to the surface of the mucous membrane, becoming rapidly desiccated by the current of air inspired through the nose. This atrophy of the mucous membrane, extending as it does up into the olfactory region, affects the terminal fibres of the olfactory nerve, and thus the loss of the sense of smell, which is a common symptom in these cases, is brought about.

The ozæna or stench may, however, be occasioned in other forms of nasal disease, by the accumulation and putrefaction of secretion behind swellings or tumors where by the ordinary means of cleansing the nose, by washing and blowing, it cannot be easily removed.

Ulcerations are rarely met with in this disease, although they are sometimes found, usually on the anterior portion of the cartilaginous septum. The general health of the individual has nothing to do with the causation of the disease, and its origin is as yet unexplained. It is likely, however, that it originates as a hypertrophic nasal catarrh, and rapidly passes into the atrophic stage, for we frequently meet with cases in which one side still presents the characteristics of the hypertrophic form, while the other side has already passed into the atrophied condition.

The treatment for atrophic nasal catarrh must be divided into two portions, viz., the removal of the accumulation of secretion and the disinfecting of the nasal cavities to remove the odor, and the stimulation of the mucous membrane, with a view to the regeneration of the serous glands.

This may be accomplished in the following manner: The nasal cavities are first cleansed with a copious stream of alkaline solution from the nasal douche; and let me tell you here, that this is the class of cases in which this much-abused instrument is not only applicable, but extremely useful without being harmful. If after this, any plugs remain in the nasal cavities, they must be removed with a pair of forceps, and the washing repeated until all secretion has been removed, as you saw me do in the case before us. The next step is to disinfect the nasal cavities. Various substances have been used for this purpose, such as permanganate of potash, chlorine water, tar water, carbolic acid solution, iodoform, and many others; but they all have either great disadvantages, or else are but partially effectual. Lately I have used a preparation called Listerine, which answers the purpose admirably, without having any

of the disadvantages of other disinfectants. It is a combination of the essential oils of thyme, eucalyptus, gaultheria, and other plants, together with a small quantity of benzo-boracic acid, and should be diluted one-half with water when used by the atomizer. The immediate effect is to at once destroy the stench from the nose, and to substitute for it the odor of the oil of thyme, which is rather pleasant than otherwise. I am in the habit of using a spray of this solution before making an examination, or before I cleanse the nasal cavities of such cases, thus mitigating very materially the discomfort to myself arising from the stench. The patient is directed to cleanse his nose with a solution of two drachms of bicarbonate of soda to one quart of tepid water morning and evening, and to throw a spray of the Listerine solution into the nostrils after the cleansing. Treated in this manner, I have seen many cases in which the odor was barely perceptible after the lapse of three or four days, and remained in abeyance throughout the treatment. The oil of thyme and of eucalyptus, besides being disinfectants, have also a stimulating effect upon the mucous membrane, and thus aid in the second portion of the treatment.

The stimulation of the serous glands to a normal action may be brought about by a variety of remedies, such as astringents in various strengths; but in my experience the insufflation into the anterior nasal cavities of finely powdered nitrate of silver, diluted with starch powder, has given the best results. Where there is complete absence of the lower turbinated bones, the introduction of a wad of absorbent cotton, which is to remain until washed out, and then be re-introduced by the patient himself, often aids in the stimulation by continually irritating the mucous surface with which it is in contact. Next in effectiveness to the silver powders, I have found a weak solution of ferric alum in the form of a spray thrown into the nasal cavities, and the natural iron water of Cresson springs is peculiarly adapted for these cases.

A treatment such as this carried out for several months has given, in my hands, most satisfactory results.

The internal administration of small doses of bromide and iodide of potassium in combination, on account of their influence upon the nasal mucous membrane, will greatly aid the local treatment. At the same time we must look to the general health of the patient, and administer tonics when their use is indicated. Whenever practicable a change of air should be advised, and the

mountain resorts are preferable to the seashore in all cases of catarrhal inflammation of the upper air passages, especially where the climate is a dry one.

COMMUNICATIONS.

CLINICAL CASES OF PUERPERAL CONVULSIONS AND PUERPERAL ALBUMINURIA, WITH REMARKS.

BY LAMBERT OTT, M. D.,
Of Philadelphia.

[Read before the Northern Medical Association of Philadelphia.]

Mrs. J., primipara, aged 23, very large boned, stout, and fully six feet tall, passed through her pregnancy with very little disturbance. Labor came on at full time. I saw her in the evening at six o'clock, and found the os open the size of a twenty-five cent piece, and the vertex presenting in the first position. Everything progressed favorably till about three o'clock the next morning—nine hours after the inception of the labor—when the head remained fixed in the pelvic cavity, with no indications of it moving forward. Being refused the application of the forceps, I waited till four o'clock, and urged her to bear down with each pain. She now complained of headache, and of it being intensified during the pains. Just after a pain I called to her and she gave me no answer, which I supposed was due to the naps she was in the habit of taking in the interval between the pains. Another pain came, and she made quite a desperate effort at bearing down, when a violent convulsion occurred, beginning in the muscles of the face, then extending all over the body, and lasting a minute or more. Immediately after the spasm, she being unconscious, I delivered the child, alive, with the forceps, and was in the act of taking away the placenta, when the second spasm took place, producing a ghastly sight, twisting her around to a different side of the bed. By this time chloroform arrived, and I straightway began its administration. After being partially anesthetized, I delivered the placenta without difficulty.

I then looked for signs of dropsy, and found none. Drawing a little urine and testing with heat, it was found to contain $\frac{1}{8}$ to $\frac{1}{2}$ albumen. Dr. F. being called in consultation, we decided to bleed to the extent of thirty ounces, to give $\frac{1}{2}$ gr. of morphia hypodermically, and 2 gts. of croton oil, which was done; the chloroform being lightly

given when twitching of the facial muscles was apparent. She regained consciousness eight hours after the first convulsion, and all up to that time was blank. The albumen rapidly disappeared from the urine; and, excepting a slight attack of septicæmic fever, she made a perfect recovery. I questioned her closely afterward in regard to the existence of symptoms pointing to kidney disease. She denied having noticed any save a slight swelling of the ankles, and in other respects she says she could not have felt better.

Case No. 2 was under the care of a very able physician, who was kind enough to give me the following verbal report: Mrs. M., aged 25, primipara, of a naturally healthy constitution, seemed to get along well till the beginning of the ninth month of her pregnancy, when an insufferable headache came on. Her urine was examined and found highly albuminous; later, a moderate amount of dropsy set in. Wet cupping to the back of the neck, dry cups over the kidneys, brisk hydragogue purgatives and diuretics were ordered, with relief of all the symptoms save the albumen, which remained in considerable quantities. She was kept under close observation, and whenever the symptoms became aggravated the remedies were pushed, with prompt relief. Her confinement passed over without any difficulty till the morning of the second day, when she complained of a return of the severe headache. The urine contained albumen. Purgatives and diuretics having been continued in moderation, were again used, but not with decided relief. In the evening of the second day after the confinement, her headache became aggravated. Wet cupping was again ordered. The cupper reached the house fifteen minutes sooner than the physician, and she requested him to wait until the doctor arrived. Just as the physician rang the bell she remarked, "'Tis the doctor; I know his ring," and when he reached the door of her room, she turned her head to look at him, and while in the act her eyes stared, neck became rigid, muscles of the face became convulsed, followed by a general spasm simulating a rigor of a minute's duration, in which she expired. The moment the physician noticed the staring and rigid countenance he opened a vein, but the blood made only a feeble attempt to flow; and while trying to induce a better spirting, she sank back dead, suffocated by spasm of the respiratory muscles, she never breathing once after the convulsion began.

Case No. 3. R., multipara, aged 35, did well during her pregnancy till the eighth month, when

she complained of her feet swelling and headache. The urine contained $\frac{1}{2}$ albumen. The usual remedies—cups and depuratives—were resorted to with considerable relief. At the time of her confinement the urine contained some albumen. Labor terminated in three hours, and everything was progressing favorably, when on the second day a severe headache and dimness of vision set in, with no fever, which only very active bleeding from the arm and depurative measures relieved. She convalesced soon. This same woman became pregnant about two years afterward, and having had a scare during the previous pregnancy, I made it a point to examine the urine every second week during the latter months. Just two weeks before the confinement her urine was tested, with negative results. Labor lasted four hours, and passed over favorably.

Two hours after leaving the house, a hasty message came, and I found quite a sudden change. The patient was propped up with pillows, expectorating bloody and frothy mucus; respirations 40 to 60 per minute; pulse 120 to 160; and all the signs of great danger. I hastily examined the uterus, which was well contracted; calmed her excitement; auscultating the chest posteriorly, I found diffused, large bronchial rales, showing pulmonary œdema. She was straightway dry-cupped, carbonate of ammonia, digitalis, and a brisk purgative were given. The urine was examined, and found to contain a moderate amount of albumen. The alarming symptoms passed over gradually, and in a week the urine contained no albumen.

Case No. 4. Primipara, aged 26, came to my office complaining of symptoms which directed my attention to the kidneys. Examining the urine, it contained one-half albumen. I prescribed, and ordered her to return in three or four days, which she did not do. The case escaped my memory until a call came for confinement. It turned out to be an instrumental delivery, and after all was over, I asked her how she got along after leaving my office. She answered: "I felt so well that I did not get your medicine; there is the prescription on the mantel." The urine now contained no albumen.

Case No. 5. Multipara, aged 32, in her seventh month of pregnancy, became enormously dropsical; even the eyelids and upper extremities were very much swollen. The urine was fully one-third albumen, and only a pint daily was passed. She suffered no inconvenience, no headache, etc., till the eighth month, when quickening ceased, and soon afterward a dead child was expelled.

The usual remedies were applied, and a rapid recovery took place.

The first case shows how little disturbance puerperal albuminuria may cause prior to confinement, even so little as to pass unnoticed, and during delivery to culminate in convulsions.

In the second case the albumen existed in considerable quantities, with moderate dropsy and the attending symptoms of a graver character, terminating in convulsions and death two days after delivery.

The third case had a moderate amount of albumen with much dropsy, and an occasional exacerbation of the attending symptoms, which were relieved by treatment. The following pregnancy showed a sudden appearance of albumen and of pulmonary œdema three or four days after delivery.

The fourth had one-half albumen, with slight anasarca in the eighth month of pregnancy, and progressed favorably without treatment.

The fifth had enormous dropsy and very much albumen in the urine; no bad effects following, except the death of the child and its subsequent expulsion.

Barker relates a number of cases of puerperal albuminuria, with and without convulsions, and one case of puerperal convulsions where no albumen was detected in the urine.

I, together with Dr. F., have seen many cases of puerperal albuminuria which have produced little or no constitutional disturbance; and in all our cases of puerperal convulsions the urine was found to contain albumen.

On inquiry of a number of practitioners having a large experience, I learn that in all their cases of puerperal convulsions they always found albumen in the urine. I have often thought, to what extent can these rare cases of puerperal convulsions with non-albuminous urine be explained on the theory of being epileptics, or having an epileptic tendency by inheritance, and the peculiar condition of the system induced by pregnancy, or the difficult and protracted labor, act as an exciting cause in developing the fit? Is there not also a possibility of these cases having an alkaline urine, and not being rendered acid previous to boiling, refuses to coagulate? I have no personal experience to offer, and I only give these points as plausible suggestions, to stimulate further thought in this direction. The following conclusion may be drawn from the foregoing cases:

A large amount of albumen with considerable dropsy is not a necessary factor in the production of puerperal convulsions.

In my experience, *some albumen* in the urine, with little or no dropsy, is an important and necessary factor in the production of puerperal convulsions.

In some cases puerperal albuminuria is comparatively a harmless trouble, passing over without any treatment. As for the spasm being a cause of the nephritis, the weight of evidence is very much against it. I have repeatedly examined the urine of children after convulsions, and found no albumen. Parenthetically, I would ask what is known as to the condition of the urine after the spasm of epileptics?

One point in the semeiology of puerperal convulsions needs to be emphasized, particularly for the benefit of those having little or no experience in these cases. Whenever you have a patient in the latter months of pregnancy, say in the eighth or ninth month, having some albumen in the urine, complaining of severe headache, and a heavy, dull feeling pervading the body, occasionally associated with attacks of dimness of vision, *then take care*. In many instances, if this patient is not handled skillfully by depurative measures, some day you may find her in a severe and perhaps fatal convulsion. There need be no fear of giving such remedies as drastic purgatives, diuretics, and bleeding from the arm, for I have resorted to them till the patient was blanched, with the happiest results.

My experience teaches me that as long as a pregnant woman having albumen in the urine is free from headache, there is no immediate fear of convulsions. The headache preceding a spasm is not sudden in its onset, but comes insidiously, being so slight in its inception as to pass unnoticed, and gradually increases until it culminates in a convulsion, or is relieved by appropriate and timely treatment. The headache preceding the convulsion during the act of parturition is sudden in its onset, as one of my cases (No. 1) fully exemplifies. This patient only complained of pain in the head during the last two pains prior to the spasm. During each pain and bearing down effort it was intensely aggravated, and while in the last pain, she was seized with the convulsion. The headache preceding the spasm after the parturient act has similar characteristics to the headache prior to the confinement, though convulsions occur less often in this period.

I will offer only a few general remarks on the treatment of the two complaints. ▲ pregnant woman with albuminuria should be gently informed that her kidneys are not working properly, and that a little medicine, with some attention, is

necessary. In imparting the news, do it in such a manner as not to create alarm. Some advocate not telling them the nature of their trouble; but if you want your patient to neglect herself, follow this plan. In uncomplicated cases of puerperal albuminuria, mild diuretics, laxatives, occasional hydragogue cathartics, and as much rest as possible, is all that is necessary. In such cases where the symptoms assume an aggravated character foreboding convulsions, more active measures are indicated: general depletion, or dry cups to kidneys and nape of the neck, and depuratives of considerable potency. Perhaps the most trying position, and one where the young physician finds himself at his wits' end, is when he has puerperal convulsions suddenly before him. If a spasm occurs before labor sets in, and he has no medicine at hand, he can only loosen her clothing, protect the tongue and open a vein; if he has a hypodermic syringe, give one-half grain of morphia, or administer an anæsthetic, the latter being preferable when the spasm is in activity; should he not give morphia hypodermically, then give chloral in 20-grain doses, either by the mouth or rectum. Having subdued the spasm, he has now to induce labor—provided it has not already begun—by Barnes' dilators, ergot hypodermically or by the mouth, and warm-water injections.

Authorities are divided as to waiting for labor, but the most successful plan is to induce labor a few hours after the spasms have ceased. While labor is going on, all tendency to spasmodic action is overcome by chloral or an anæsthetic. After the child is born, depuratives in moderation should be given, at the same time keeping her gently influenced by chloral. Even when all depurative remedies are contraindicated, give diuretics at any rate. In other cases where labor is going on, the presenting part being in the pelvic cavity, and convulsions occur, subdue them with your remedies, then hasten delivery, and the after treatment is on the same general principles as previously enunciated. When the spasm takes place after the delivery of the child (my experience teaches me that they are not less dangerous than those at other periods) general principles are again indicated. A plan which I follow in cases of albuminuria in the latter months of pregnancy is to caution my patients, in such a manner as not to excite alarm, that whenever headache sets in to notify me immediately so that I can give them the proper attention; and when they do report I make preparations for any emergency, and keep my eyes wide open.

1531 North Seventeenth Street.

FLORIDA AS A HEALTH RESORT.

BY M. J. HALLORAN, M. D.,
Of Worcester, Mass.

Compelled, during convalescence from an attack of pneumonia, to seek a warmer climate, I have during the current year passed several months in Florida, most of the time in Jacksonville and St. Augustine. This brief resumé of the present condition of Florida, particularly considering its advantages and disadvantages as a health resort, will be founded on personal experience, supplemented by the more extended observations of Drs. Kenworthy and Baldwin, of Jacksonville; Dr. Logan, of Atlanta; Dr. Jacques, of Fernandina; and Dr. Charles E. Lee, the learned editor of Copeland's Medical Dictionary.

When the merits of any particular place or region, as a health resort, come into question, the first factor to be considered is its condition as regards climate. The climate of any locality, professionally speaking, depends upon its temperature, atmospheric vicissitudes, prevailing winds, humidity, its elevation above the sea level, proximity to the ocean or oceanic currents, its contiguity to lakes, rivers, or mountains, its condition as regards soil, drainage, vegetable productions, malaria, general sanitation, etc.

Temperature is a very important factor in climate, a very large proportion of the profession advocating a warm, dry, sunny climate for the successful treatment of many diseases, particularly those affecting the pulmonary organs. The climate of Florida leaves little to be desired at this point of view. The thermometer rarely falls below 30° in winter, and seldom goes above 90° in summer.

Dr. Baldwin's tables, kept for the Smithsonian Institute, and compiled from the mean of three daily observations during twenty years, from 1844 to 1867, at Jacksonville, show the ordinary temperature to be in January 55°, in February 58°, in July and August 82°, falling during the month of December to 52°.

During the first four weeks of the current year, which I passed in Jacksonville, the temperature ranged from 55° to 65°, but the fourth week was stormy and chilly, with strong northwest winds. For several days a light overcoat was necessary, and during the entire period of my stay, I found no inconvenience from wearing the heavy under-clothing and winter woolen business suit I had worn in Massachusetts. The nights were uniformly cool and rather damp in Jacksonville; blankets were a necessity, and in the morning I

found my windows (fronting directly on the St. John's river) covered with moisture; in fact, the river itself was overshadowed with an impenetrable mist until 9 a. m., when it was slowly dissipated by the rays of the sun.

Jacksonville is a pleasant place as a residence; the streets are wide and shaded by magnificent live-oak trees, rendered picturesque by the hanging masses of Spanish moss. The use of the wild orange as a shade-tree makes walking more interesting, for the orange tree in winter, with its dark green glistening foliage and bright yellow fruit, is a beautiful object, especially to the visitor who has left behind him two or three days previously the piled-up snow banks, naked trees, and searching blasts of a northern winter.

The complaint is frequently made that there is nothing to interest the visitor in Jacksonville—that it is merely a stopping-place en route to some place "up the river."

Such, in reality, is the use to which it is put by many visitors, who lounge out the period of stay at the hotels. Yet a very pleasant sojourn can be made there. The streets are heavy and sandy, and carriage riding is not so pleasant as saddle exercise or walking. There are many pleasant walks: beyond the Way-cross Station, along the shell road, by the side of the river, or across the river by the railroad ferry, and along the road parallel to the river, furnish many points of beauty, and give a good idea of semi-tropical scenery. In fact, to one who is willing to take open-air exercise and is not afraid to walk, Jacksonville need not prove uninteresting; the weather is generally such that a weak person can be out almost any time during the day; we have seen invalids on the streets, and in the woods, who, at the same time of the year, would be unable to leave the house at the north.

During our stay in the city, a lady died who had come there seventeen years previously suffering from consumption; her life had been indubitably prolonged many years by residence in this mild climate.

The variations in temperature at St. Augustine, where I passed the month of February, are still less marked; the army records for twenty years show an average variation of but 23°.

There is still more inducement to pass the time in the open air in St. Augustine; the weather during my stay was delightful, day after day was clear and sunshiny, the thermometer registering between 70° and 80°.

Early in the morning it was frequently rather close, but later on before noon a breeze sprung up,

which rendered out-door exercise a pleasure. And the city itself is so very interesting; it is true, all its sights can be seen, tourist-fashion, in two or three hours; but to the visitor seeking health, a much longer stay fails to exhaust the items of interest. The invalid can enjoy any part of the day in the open air; and the moonlight evenings, which have lost none of their charm since the writer on "The Ancient City" so romantically described them in the article in *Harper's*, are generally passed on the wide southern verandas, or listening to the music discoursed by the excellent military band, on the plaza.

We have become acquainted with invalids in St. Augustine, suffering from consumption, chronic bronchitis, asthma, chronic rheumatism, and other complaints, who passed their time in the open air, sailing to the north and south beaches, going on trips to Matanzas, fishing, etc., individuals who at the same period of the year would be almost entirely confined to a close, over-heated apartment at the North. Northern ladies and their families are generally more content in St. Augustine than elsewhere in Florida. It is an undoubted fact that Northern-born ladies are not, as a rule, favorably impressed with life in many sections of Florida. This appears somewhat strange when we consider that the climate, fruits, garden dainties, and the like, such as women are usually fond of, are so abundant. The principal source of their objection is the same as in all new countries; women prefer old, settled communities, churches, schools, society, sidewalks, and intimate social intercourse. The sandy soil, heavy roads, and absence of sidewalks, especially in South Florida regions, are at the foundation of the prevalent discontent among the women. In the towns in Northern Florida, where improvements are more general, there is more content among the female members of the family.

In the matter of healthfulness, St. Augustine must take a high place among Florida resorts. Malaria is almost unknown, and the constant sea breezes moderate the cold spells in winter and mitigate the heat of summer. Frosts seldom occur, and the mean winter temperature is 58.8°. Just before I left the city, we had a series of thunder storms, the rain pouring down incessantly two or three afternoons in succession. The rainfall was considerable, but it was almost entirely absorbed by the sandy soil in a short time, and in less than twelve hours it was possible to walk dry shod on any of the streets.

After these storms, vegetation was bright and beautiful; the banana plant, looking hitherto like

a gigantic withered cornstalk, put forth green shoots; the yellow fruit and dark glistening leaves of the orange tree looked brighter, and even the stretch of pine barren between St. Augustine and Jacksonville, along the new and well-appointed St. John and Halifax river road, took on a different aspect, and appeared less monotonous. Four days later, I was in the midst of a driving snow-storm in Massachusetts.

After a season passed in Florida, one can readily regard as absurd the dictum of fashion, which sends so many families from comfortable homes, large, well-aired rooms, and accumulated home comforts during the summer season, to crowded hotels, discomforts of every description, and the costly prices of seaside resorts, to avoid the heated tern, which, except in the largest cities, can be passed with equal immunity from disease at home. But it is not considered at all necessary to avoid the extreme and sudden variations of temperature of the Northern winter, during which a great part of the time is passed by even the most robust within doors; the more weakly remaining almost the entire winter in close, over-heated rooms, with the air loaded with noxious exhalations and coal-gas. It is true that formerly it was considered necessary to undergo the discomforts of a journey to the South of France or to Italy in search of a mild and pleasant winter climate. But to-day, with the very much improved and rapidly-improving railroad facilities at the South, and the rapid influx of Northern capital and enterprise, a season in Florida is almost as enjoyable as one passed at one of the Continental winter resorts.

As regards advantages of climate, the average temperature at Cannes for the five winter months from the first of November to the last of March is 50.8°; at Nice 49.9°, and at Jacksonville 58.7°.

Florida has always ranked high in the climate-cure of pulmonary diseases, and the general testimony of invalids and practitioners bears out this view.

Of course, if the case is already hopeless, if the patient is emaciated to the last degree (we have seen such individuals in Florida), then no great benefit can be expected; and the rapidly-fatal result which often ensues on their removal there can by no means be laid to the climate, but is often caused by the fatigues of travel, and the absence of the home care and nursing to which the enfeebled individual has long been accustomed.

Yet Dr. H. A. Johnson, of Chicago, states: "I had about fifty patients last winter in Florida and Georgia, and they came back better. Even those

in whose lungs cavities existed were better than they would have been if they had remained in Illinois." Dr. Wilson, late Medical Inspector of Camps and Hospitals, U. S. A., remarks: "Neither upon the southern coast of France nor anywhere under the bright Italian skies, can a winter climate be found so equable and so genial to the delicate nerves of most invalids, as can be enjoyed in our sanitary stations in Florida."

This remarkable freedom from disease was noticed in the garrison who occupied St. Augustine during the British possession; and to-day you will meet in "ye ancient city" men who have a kindly memory of the climate since they formed part of the U. S. troops who occupied the place during our late civil war.

As Dr. Jacques, of Fernandina, writes: "There are two things which the invalid cannot enjoy to their full extent at the North in winter—fresh air and sunshine. These are the things to come South for, and coming for these there will be no disappointment. The fresh air you will get every hour of the day or night; you cannot shut it out if you would. As for the sunshine, one bathes in it, breathes it, drinks it in at every pore, till it permeates the whole system; and there is no medicine like it. It is the invalid's own fault if he does not get enough of it; to what end is the South 'sunny,' if one will shut himself up in a darkened room?"

But in forming an opinion regarding climates, many factors must be considered; and altitude is of less importance than temperature, prevailing winds, dry soil, and low mean relative humidity. "With regard to the temperature of the air, it is absolutely certain," says Prof. Buhl, "that it is not the mean temperature which regulates the frequency of catarrh or phthisis, but only the larger, sudden, and oft-recurring vacillations of temperature, which the compensatory power of our body is unable to resist." Therefore the temperature of the air and its rapid vacillations must be regarded as exciting causes of inflammatory phthisis.

Atmospheric changes in the North and West are sudden and great, but in Florida they are infrequent and not extreme. At times what are termed "cold snaps" occur, but they seldom last over two or three days, and at any time the invalid may take exercise out of doors in the middle of the day. Owing to the low level of the land, the absence of snow and ice, and the warmth of the soil for a long distance to the north and west of the State, and the influence of the winds from the gulf, the northerly and westerly winds are

robbed of their harshness and refrigerating effects before they reach Florida. Easterly winds are the prevailing ones during the winter months, but owing to the proximity of the Gulf Stream, with its vast volume of heated water, to the east of the coast, these winds are also robbed of the harsh and searching properties which characterize them in most localities.

In a word, Florida appears to offer more attractions and advantages as a winter resort for invalids than any other State in the Union. The temperature is favorable, the mean relative humidity is peculiarly adapted to the treatment of all forms of pulmonary disease; the air is salubrious, and in a large portion of the State dry and bracing; atmospheric changes are infrequent, and not so great as in other sections east of the Rocky Mountains.

The State possesses insular, interior, dry, and moist localities, semi-tropical and cooler sections, and if the nature of any given case should necessitate a change of base, a suitable climate can be reached in a few hours and at a trifling expense.

HOSPITAL REPORTS.

NEW YORK HOSPITAL.

CLINIC OF PROF. WILLIAM H. DRAPER.

Reported by W. H. SEELYE, A. M., M. D.

Constitutional Syphilis.

You will remember this patient, gentlemen, as the one whom I presented to you two weeks ago (see REPORTER, p. 329), with a general eruption over most of his body. You remember his case was a curious one, because he gave a history of having had several chancres. I think at three separate and distinct periods he had chancres or ulcers on his penis. But after the first and second there were no constitutional symptoms, while after the third, contracted last summer, there were. This sore was unique, and made its appearance, as we have since learned, after the classical period of twenty-one days from the time of infection. And six weeks after the sore appeared, he broke out with the roseola, which you saw; and you remember there was also a condition of general adenitis, and an especially marked swelling of the posterior cervical glands and those of the groin. The roseola and the swelling of the face, and the watery effusion of the eyes, were so pronounced that he presented very much the appearance of a man with measles.

He was put upon mercurial treatment, and now you see the eruption has almost disappeared, the face has a natural expression, and the swelling has gone, and he is not at all the same man in appearance that he was when you last saw him. The eruption has not yet entirely disappeared from the head and body, but it is more sparse and

less distinct than it was. But it still has a copery hue, and does not entirely disappear on pressure, as do the spots in a non-specific erythematous eruption. There is still some swelling of the posterior cervical, and the glands of the groin, but it is not so marked as it was. On examining the throat, I find no eruption there. He is now taking the biniodide of mercury, and is in the first stage of pyalism. If you will examine his gums, you will see the peculiar appearance they present in this stage. They are red and swollen and soft, and at their junction with the teeth thick sordes has collected, which contrasts strongly with the bright red margins of the gums. The peculiar fetor of the breath is also well marked.

There is one peculiarity about the eruptions of the secondary period of syphilis, and that is that when a patient has had one attack of an eruption, he is by no means protected from a second attack within a period of two years. But this liability to an occurrence depends much upon the treatment of the case. If within this period you cease from the constitutional treatment, and allow the patient to go back to his former habits of living and drinking, before long he will probably come back to you again with an erythematous or papular eruption on the integument of the body and extremities, or on the mucous membranes lining the different orifices of the body, that is in the mouth or throat or anus, or on the glans penis. It is important to remember that there is this liability to a recurrence, for from eighteen months to two years after the beginning of the treatment. Ricord claimed that it was necessary to keep up the treatment for eighteen months, and his plan was to keep the patient on mercury alone for the first six months, on mercury and iodide of potassium combined for the second six months, and on potassium iodide alone for the third six months. This treatment he thought might be successful in extirpating the disease. There is not now as much faith in this plan of treatment as there was a few years ago; yet the general opinion is still that the patient should be kept under the appropriate treatment for at least a year or eighteen months. I believe, however, that none of the cases of constitutional syphilis are ever perfectly cured. I would keep the patient under observation and direct his mode of life, and withdraw all stimulants, and on every recurrence of the eruption renew the specific treatment.

Iodism.

The patient, J. C., was admitted on October 3. He is single and a laborer, age 39, a native of the United States. Has been accustomed to drinking ale and beer, but not to excess. Twenty years ago he had a chancre, which was followed by a secondary eruption. He was successfully treated for this, and was well for a number of years. Five years ago he had an attack of rheumatism, affecting all the joints, which lasted for eight months. He also complained of pain in the cardiac region at the same time. Four years ago a rash broke out on his scrotum, anus, and thighs, which exuded a watery fluid, which dried into scales or crusts. Last August, several ulcers appeared on his ankles, which he treated himself, with black wash and other local applications. On

his admission to the hospital October 3, he presented an ulcer on the inner side of the left ankle and another on the outer side of the right ankle. These were irregular in shape, and showed no tendency to heal. The ulcers were treated locally with iodoform, and he was put upon the mixed treatment for constitutional syphilis.

October 20. The ulcers are sluggish, and not healing rapidly.

November 3. A Martin's rubber bandage was applied for the purpose of keeping up pressure on the neighboring vessels. On October 28, over two-thirds of the right leg, and on the anterior portion of the left, appeared an eruption of small red spots, attended by much itching. These continued to increase in extent and size, and they poured out an exudation, which dried and formed crusts upon them.

November 11. The ulcers are much improved, but the eruption continues to spread.

November 19. Patient was put on liquor potassii arsenitis, 5m three times a day, to try its effect both upon the eruption and the ulcers. The mercury and potassium iodide were stopped.

November 22. The eruption has spread to the arms and thighs, where it is circumscribed and papular, and it has become diffuse over the legs, which the hardened exudation has coated with a thin, scaly crust. Citrate of potash, 30 grs. three times a day, was added to the treatment.

November 25. Fowler's solution was discontinued. The ulcers are almost cured, and are doing well.

November 26. The ulcers on the ankles are entirely healed. The dose of the citrate of potash has been increased to 40 grs. three times a day.

Since the patient has been under observation, his bowels have been regular and appetite good, and there have been no urinary symptoms. For seven and a half weeks he took $\frac{1}{2}$ gr. of the biniodide of mercury and 10 grs. of the iodide of potash thrice daily, but eight days ago they were discontinued. He says that he had no cutaneous eruption in childhood. A plain roller bandage was later on in the treatment substituted for the elastic bandage. On admission, his pulse, respirations, and temperature were normal, and have continued so up to the present time.

Gentlemen, the striking points in this man's history are, that previous to his admission he seems to have had a tendency to rheumatic affections for some years, and also that he underwent a course of treatment for a primary syphilis contracted twenty years ago, and no constitutional syphilis has since manifested itself in any way, until he entered the hospital with two ulcers on the ankles. But these ulcers were described in such terms as to leave no doubt of their syphilitic character, for the features of a tertiary ulcer are very characteristic.

Since he came into the hospital he has developed the condition of affairs which I now show you. You see it is an eruption upon the skin of the legs chiefly, and reaching from his feet to his hips, and it also covers the arms to a considerable extent, but it is not much developed upon the rest of the body. This began as a disseminated eruption of papules, which grew into vesicles and pustules, and they increased in number until

finally there was a general inflammation of the skin.

But now, as you see, below the knees the papules are no longer disseminated, but have grown together so as to present only a general superficial dermatitis, and the hardened exudation has encrusted the whole leg with a dry scaly envelope. In former times, and even now also, this was called an eczema; by which was meant any lesion of the skin in which there was a pouring out of fluid upon the surface. But the meaning of this term has now become enlarged, and it is applied to any inflammatory disease of the skin which involves the superficial layer of the corium, and results as a consequence in the formation of vesicles, papules, and pustules or scales. There are two varieties, the moist and the dry. And this is a moist eczema which we have here, the serous exudation having become dried into these dirty, grayish scales, which you see. These are very different from the scales of psoriasis, which are made up of the epidermis proper, and not formed by the desiccated exudations, as are these.

When we come to examine the parts above the knee, we find a very different appearance, and such as was at first presented by the parts below the knee, namely, a number of sparse and disseminated papules, vesicles, and pustules, with healthy integument filling up the spaces between them. Upon close examination I find that some of these papules occur just at the orifices of the hair follicles, and therefore we may conclude that the inflammatory process had its origin in these hair follicles. Other papules, however, show no connection with any hair follicles, but still they have such a characteristic, individualized appearance, as to suggest that they have their origin in an inflammatory process which has taken place in the sebaceous follicles. The disease in this man is really a follicular eruption, principally involving the sebaceous follicles which open into hair follicles. This communication of sebaceous with hair follicles, is very general over most of the body, but on the face and scalp they are mostly diffused and separated from the hair follicles. You see here the two stages of this eruption well illustrated. Beginning discrete, as on the thigh, and ending as on the leg, in an eczema. The same papular eruption, but less marked, is seen on the arms. But here there are no vesicles, and no pustules. So much for the character of the lesion.

But you should not be satisfied with the simple diagnosis of a follicular disease of the skin with an eczema of the legs. In the olden times great stress used to be laid upon the importance of diagnosing the papular from the vesicular, and the vesicular from the pustular eruption, as each was supposed to represent a distinct variety of the disease; and he was a good diagnostician who could tell with certainty the variety of the disease from the character of the eruption alone. But there is no longer that degree of importance attached to the precise character of the lesion, as there was formerly. For now we know that a cutaneous lesion is often not the whole of the disease, but simply a local manifestation of it.

The next important step in the study of this case is to find out the essential cause of the lesion which we see. The study of skin diseases is

especially valuable to every student of medicine, because they suggest to him those methods of examination which every scientific physician follows in making the diagnosis of all diseases. For you have a lesion, and very varied symptoms to study in both. In many cases you have the whole process of inflammation most perfectly illustrated in the progress of a cutaneous eruption. And a lesion produced by a parasitic disease of the skin, illustrates the course of the same class of maladies in other organs. In fact, the skin is a microcosm of pathology for the doctor, and therefore you should avail yourself of every opportunity for the study of cutaneous lesions. To find out the cause of the eruption is, as I have said already, the principal thing in the diagnosis of a skin disease. And for convenience, we may divide the causes into two classes, namely, external and those which arise within the body.

The external include atmospheric causes and all those which are material, and all which operate directly upon the integument. There is nothing in the history of this patient to suggest that this eruption was caused by any material or external application to the skin, such as heat, cold, or blisters, or by any peculiar atmospheric conditions; therefore we are obliged to refer it to some internal cause.

Possibly the syphilis suggests itself to you as a cause. But you must remember that this man was under constitutional treatment for a syphilitic ulcer when this eruption appeared, and the ulcer healed; and it is not to be supposed that another syphilitic ulcer would appear while one was healing under the influence of treatment. So we must exclude this as a possible cause. But, you may ask whether or not the eruption had anything to do with the treatment itself of the syphilitic ulcer. And this would be an extremely pertinent question. You should always think of the fact that drugs are themselves often the cause of cutaneous eruptions. Belladonna, for instance, sometimes causes a general erythematous eruption like that of scarlet fever, and copaiba an eruption which may easily be mistaken for syphilis. And in nervous and sensitive people opium may produce a nervous irritation of the skin which sometimes results in a troublesome eruption; and there are many drugs which cause neuroses in the way of hives. But there are two classes of remedies used very largely as medicines which are responsible for a good deal of cutaneous irritation, and one of these we find has been used here. I refer to iodine and bromine. These are remedies which you know are very largely used, the one in rheumatic and syphilitic diseases, the other in a very large class of neuroses. You will frequently, in the use of iodine, and still more with bromine, have occasion to observe on the patient an eruption of an erythematous vesicular character, which sometimes results in an obstinate inflammation of the skin. And inasmuch as both these remedies are employed to a large extent, it is important to bear this important action in mind. Now I believe that this man has been suffering from iodism, and the form which it has assumed in him is a dermatitis. But the commonest form in which iodism is manifested, is not by an integumentary eruption, but by an irritation of the mucous membranes. Some people cannot

take this remedy at all without becoming afflicted with an intolerable naso-pharyngeal catarrh, while others will suffer not so much from inflammation of the mucous membranes as from irritation of the external surface of the body. The form of eruption which iodine and bromine produce is a folliculitis, or an inflammation of the sebaceous follicles. And the commonest kind of lesion seen in persons taking iodine, but who are not very sensitive to its influence, is an eruption of acne, involving by preference the face, neck, and breasts. In some instances the iodism will produce such an eruption as we have here, which you will remember was follicular at the beginning, and which is more acute on the limbs than where the sebaceous follicles are more independent of the hair follicles. It is a vesicular and pustular eruption, with a tendency to run together and form a general inflammation of the integument. Sometimes it is a general eruption over the whole body, but as a rule it is confined to the extremities, and chiefly to the lower limbs.

I do not know why bromine and iodine should produce a sebaceous folliculitis, but it would seem that this is the particular channel by which nature seeks to rid the system of these substances. These medicines do not undergo any change in the circulation, but they are eliminated just as they are taken, and they are found unchanged in the urine and the excretions. And a large proportion of the remedies used are eliminated from the system by the kidneys, but some by the skin as well, and these latter cause cutaneous eruptions.

It is also of importance to bear in mind the possible means of preventing this irritation of the skin. From my personal experience, I have been led to think that by giving potassium iodide in combination with some other salt, or a diuretic, this effect might be prevented. I therefore give with it, usually, the citrate of potash or soda, or the bicarbonate of soda or potassium, or the muriate of ammonium, and I believe that the metal is thus more easily eliminated by the kidneys than when it is given alone. The same may be true, though, perhaps, not to the same extent, of potassium bromide when given for nervous affections. This tendency to produce a cutaneous irritation, sometimes becomes a very serious obstacle, in the treatment of such diseases as epilepsy for instance, where the remedy must be kept up for a long time; for some individuals are so sensitive to its action, that they cannot take it at all without immediately provoking a more or less general folliculitis. And I have seen patients rendered so offensive by the exudations, and so helpless by reason of the superficial ulcerations which accompanied the eruption, as to make it almost impossible for others to take care of them, or for them to move about themselves. Therefore, as a means of preventing this condition from following the use of bromide of potassium, I would suggest the same manner of combining it with a diuretic salt, as I use with the iodide. It has been further suggested that arsenic given with the bromide would prevent this complication; but I have not had enough experience in this class of diseases to express an opinion on this plan of treatment. This man, however, has been taking Fowler's solution with the iodide of potassium,

and it does not seem to have done him much, or any good. Yet I should think that it ought to have as good an effect when administered with the iodide, as with the bromide of potash; while I also think that the diagnosis of this eruption as caused by the iodide, is justified by the history of the case, and by the appearance, development, and distribution of the eruption. And now, having diagnosed the cause, we have, I believe, diagnosed the disease. And the diagnosis of the cause which has brought about the changes involved in the lesion, is, I think, the only true basis for the rational treatment of the disease.

However, it is not always in your power, as it is in this case, to apply the rational treatment, which mainly consists in removing the cause. Yet in a large number of the cases of inflammatory diseases of the skin, this rational treatment is possible to apply. In the case of parasitic eruptions, by removing the parasite we cure the lesion. And in the pathogenetic and autogenetic skin lesions, which are due to causes generated within the body, we can also apply the rational treatment in many cases, and remove the cause of the disease. In some individuals certain articles of diet in the process of digestion will cause a cutaneous irritation. You should know what these are, and withdraw them from the patient's use. Again, there are many eruptions which owe their origin to what is called the rheumatic habit of body, or to that peculiar condition of the system called gouty, which manifests itself in various forms of dyspeptic troubles. This class should be relieved by the same means that you would employ for the treatment of other rheumatic and gouty lesions. Again, we know that syphilis produces certain integumentary lesions, and also that the syphilitic poison is, to a remarkable degree, under the control of certain medicines. Therefore, to cure the specific lesion, you should use the specific remedy. So you see that, in a very large proportion of the maladies under observation, we have the ability to apply the rational principle of treatment by removing the cause.

We have put this patient on a diuretic, the citrate of potash, and we are treating the parts locally with a protective ointment for the purpose of allaying the severity of the inflammatory process, which was very active a few days ago. The diuretic is for the purpose of ridding the circulation of this irritating poison. But the most essential point in the treatment is to stop the iodide of potassium. In a week or ten days we will see what is the result of this treatment.

MEDICAL SOCIETIES.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Thursday evening, February 28, 1884, the President, Dr. Tyson, in the chair. Dr. W. E. Hughes presented

Two Cases of Suppurative Nephritis.

In both of these cases the kidney lesion had been preceded by cystitis, in one of some months standing, in the other of more recent origin. In both of them there was a history of gonorrhea,

and in one well-marked symptoms of stricture of the urethra; in this case the cystitis seemed to have been originated by septic matter carried into the bladder on a catheter, although a tendency to inflammation had most likely been developed by the long-standing stricture. In one case the kidney lesion may have originated in emboli derived from a suppurating surface, though this is unlikely, from the fact that no such emboli were found elsewhere.

Case 1. A man, æt. 55 years, had locomotor ataxy for years. He had gonorrhœa, but following it no change from the normal in urination, so that it is scarcely probable that there was any stricture of the urethra. Six months ago, as the result of exposure, a cystitis developed, with the usual signs of frequent passage of urine containing large quantities of mucus and pus; there were no tube casts, and no more albumen than could be accounted for by the pus corpuscles present. After being under observation about two months, large bed-sores developed over the sacrum and trochanters. They soon induced a septicæmic condition, which rapidly produced death. At the autopsy the nervous lesions characteristic of locomotor ataxy were shown. The urinary bladder was dilated, its walls thickened, its inner surface crossed in every direction by bands of hypertrophied muscular tissue, the mucous membrane thickened and slate-colored. In the kidneys were numerous cone-shaped masses, in which the tissue of the kidney was broken down and infiltrated with pus, and the blood vessels filled with micrococci. The remainder of the kidney tissue appeared healthy. There were no abnormal appearances about the pelvis and ureter.

Case 2. A male, æt. 72 years, had several attacks of gonorrhœa, and symptoms of urethral stricture, lasting over 32 years. The stricture had been dilated several times, but during the six months before he came under observation it had been neglected, and had begun to grow troublesome. When first seen his urine was normal, and there were no signs of cystitis. He had been failing in health for some time, and was much troubled by a cough. Physical examination showed breaking down of the lung structure at the apices. A few days after coming under observation his nose bled so uncontrollably, that it became necessary to plug his posterior nares. Soon after this, his stricture almost preventing the voiding of urine, a catheter was passed into the bladder. The next day he complained much of pain and tenderness in the region of the bladder, and the urine, which was passed every few minutes, contained large quantities of blood, pus, and mucus. The acute symptoms were soon relieved, but the urine continued loaded with mucus and pus; in fact it was often so stringy that it was only with the greatest difficulty that he could pass it. It never contained casts, nor more albumen than could be expected when there was so much pus and blood. He died two months after he was first seen. The autopsy showed tuberculosis and disintegration of the pulmonary tissue. The kidneys were identical in appearance with those in case 1, with the addition that their pelves contained numerous particles of uric acid. The cavity of the bladder was small, its walls thickened and hypertrophied, the mucous

membrane dark red, thickened, softened, and thrown into folds.

Dr. Tyson said that the relation of bladder to kidney trouble was as yet pretty much guess-work, although it is certain that in a prolonged cystic disease suppurative interstitial nephritis will sooner or later arise. But rarely can we state from an examination of the urine that renal disease has supervened. He happened, however, now to have under his care two cases of cystitis with renal disease, in which it was comparatively easy to determine the presence of the latter along with the former, by reason of the presence of compound granular cells and fatty tube-casts in addition to pus. The character of the casts pointed rather to tubular nephritis than to the interstitial form, contrary to the ordinary belief with regard to these cases.

Dr. E. T. Bruen exhibited

A Specimen of Enlarged Bronchial Glands which had caused Intra-Thoracic Pressure.

These specimens were taken from the body of a man æt. 44, who had suffered for some years from chronic bronchitis. The bronchitis was probably due to his exposure to the fumes of coal in the gas works. There was no emphysema. The bronchial glands are deeply pigmented and much enlarged, forming in all a mass five inches long, three inches broad, and two inches thick. This enlargement surrounds the trachea, and slightly overlaps it anteriorly. A portion of the formation covers the origin of the right bronchus, but the left is also somewhat enclosed by the enlarged glands. In addition, many isolated bronchial glands will be found much increased in size.

The lungs presented evidences of chronic bronchitis and lymphatic irritation. The aorta is atheromatous and dilated. Heart normal. This specimen is exhibited chiefly to illustrate the possibilities of intra-thoracic pressure from this source. It will be seen that these enlarged glands occasioned serious pressure upon the lower portion of the trachea and the upper portions of the bronchi. During life there were many symptoms traceable to reflex irritation of the pneumogastric nerve, and there were also symptoms of pressure upon the œsophagus. The writer has published a detailed account of the symptoms incident to similar conditions in the *American Journal of Medical Sciences*, July, 1883. The cause of the enlargement of the bronchial glands in this case must have been the chronic bronchitis, although similar enlargements sometimes follow dilatations of the aorta. It is curious to note that degenerative changes in the lungs, or hepatization, were not observed.

Dr. Shakespeare said that the case was of interest from several points of view, one of which was the so great enlargement of the bronchial glands without either lung or any other thoracic disease. It was an extraordinary thing that the enlargement had progressed so far without any apparent primary point of origin in the tissues in which the lymphatic radicles take their rise.

Dr. Tyson was inclined to attribute their enlargement to anthracosis.

Dr. Bruen said that one of the latest writers upon bronchitis states that the reason for the intractability of chronic bronchitis is due to the

constant co-existence of lymphatic disease, thus inducing venous congestion, catarrh, etc.

Dr. G. E. de Schweinitz presented

A Case of Cystic Degeneration of the Fœtal Kidney, and said, I desire to present this evening an example of cystic degeneration of a fœtal kidney. The specimen was removed from an eight months' old fœtus brought to the University Museum by Dr. George Horn, of this city. The fœtus in question, in addition to this anomalous condition of its kidneys, presented also other interesting abnormalities, having, at the position of the posterior fontanelle, a large meningocele; further, an imperfect development of the external genital organs; and last, but not least remarkable, six fully developed fingers upon each hand, and a similar number of equally fully developed toes upon each foot. Upon opening the abdominal cavity both kidneys were found to present appearances of the one I exhibit to-night. It is enlarged, having a length of about $4\frac{1}{2}$ inches. and a breadth of about 3, or about the size or a little greater than the size of a normal adult kidney. The capsule can be detached with a moderate degree of ease, and the organ is surrounded with its usual envelope of peripheritic fat. Both upon the free and also the cut surface are seen numerous cysts, varying in size from a small marble to a split pea, or even smaller, each cyst having a moderately firm capsule, and upon incision discharging fluid contents. Very distinct lobulation of the kidney is a marked feature. It is perfectly plain that we have here a specimen of what is referred to by systematic writers upon pathology as congenital renal cysts. Rindfleisch speaks of kidneys of this sort usually producing death to the child either during birth or immediately after, by pushing the diaphragm up, and thus occupying space necessary for the movements of the lungs. He further indicates that the Malpighian corpuscles constantly prove the points of departure for these cysts, although degeneration in the continuity of a urinary tubule may also contribute in the formation of the cystoid change. Both Virchow and Rindfleisch consider "an intercalation of a mass of connective tissue between the renal calyces and renal papillæ" as a cause of this congenital cystoid degeneration. A rather hurried microscopical examination of this specimen reveals the following points: Nearly a total absence of any true renal structure, the greater mass of the organs being composed of connective tissue, through which are scattered numerous free nuclei; cysts, the walls of which are lined with a single layer of cubical epithelium, and in such which evidently arise from Malpighian corpuscles, the remains of the vascular tuft is sometimes seen, the wall having been drawn back from the vascular coil, as Rindfleisch puts it; quite large vascular channels and blood-vessels usually filled with blood corpuscles, and finally decided areas of fatty infiltration, the fat-cells having inserted themselves between the connective tissue. Further and fuller microscopical examination of the organ may probably discover other and different changes which have not been described. John Klein demonstrated renal cysts in an adult case to arise from degenerated Bowman's capsules, which contained cholestrum crystals, fat granules, and calcareous grains, or, as he expressed it,

"renal sand." Such conditions were not discovered in this case.

Dr. Tyson said it was remarkable how long persons with this congenital cystic trouble will live. Adults are found post-mortem with kidneys the size of a fœtal head, with cysts as large as marbles, and apparently no renal tissue left, conditions which have evidently existed for years.

Dr. C. B. Nancrede exhibited the specimens from a case of

Round-celled Sarcoma of the Superior Maxilla. Excision of that Bone with the Molar.

Thos. A., æt. 56 years, was admitted to the male surgical ward of the Episcopal Hospital in the fall of 1883, with what appeared to be an ordinary epulis of the back part of the right superior maxilla. On November 2, 1883, Dr. Packard removed the growth with the contiguous alveolar processes, and wiped out the wound with a 20-grain solution of chloride of zinc. Microscopic examination of the growth showed it to be a small round-celled sarcoma. It rapidly returned, so that in two weeks the growth was larger than when first removed. Dr. Packard removed this second growth with the outer wall of the antrum, the alveolar border, and most of the maxillary tuberosity. Wiped out again with chloride of zinc solution, all morbid tissue seemed removed; yet in less than six weeks it again began to fungate, and during the past week its enlargement can only be compared to that of a mushroom, the increase from day to day being readily perceptible. On February 27, 1884, the growth nearly filled the mouth and pharynx, and pressed upon the tongue so that deglutition was almost impossible. Accordingly, upon that day I proceeded to perform a formal excision of the upper jaw, removing also the right molar and part of the left side of the ethmoid. Owing to the efficient assistance of my colleague, Dr. Forbes, the hot iron was unnecessary, the internal maxillary being caught and tied with singularly little loss of blood.

To Prevent Pitting in Small-pox.

In the *Pharm. Central*. we read that for this purpose M. Schwimmer recommends the external employment of ointments containing carbolic acid or thymol.

	I.	Parts.
Carbolic acid	5	
Olive oil	40	
Prepared chalk	60	
	II.	
Carbolic acid	5	
Olive oil	40	
Starch	40	
	III.	
Thymol	5	
Linseed oil	40	
Prepared chalk	60	

In experiments carried out by the author on small-pox patients, treating only the face, it was found that the drying action set in from four to eight days earlier than in the parts of the body not operated on. The ointments form a protective covering, prevent the dangerous internal suppuration, and entirely prevent the formation of scars.

EDITORIAL DEPARTMENT.

PERISCOPE.

The Diagnostic Value of Severe Coryza in Chronic Bright's Disease.

Dr. A. Ostertag read the following paper before the American Rhinological Association (*St. Louis Med. and Surg. Jour.*, February, 1883):

Gentlemen of the Association: I must begin my paper with an apology, on account of the very short time that was allowed to me for working it out, as the solicitation of our honored president reached me only two days ago; but the newness and extreme importance of the subject will be my best excuse for bringing it to the knowledge of the Association, even in this very imperfect form.

About nine months ago, I saw in a number of the *Cincinnati Lancet and Clinic*, a very able paper by Arthur V. Meigs, read before the College of Physicians and Surgeons of Philadelphia, entitled "Clinical Observations on Albuminuria," which he bases on the considerable number of sixty-two cases observed by himself and his father during a period of nine years. Leaving aside his other statements, which are foreign to our purpose, I will give his observations on the subject in his own words, as he most emphatically expresses himself thus: "Another symptom of Bright's disease, which I have frequently noticed, and have never heard described, is coryza of such a character that it gives rise to a very much greater distress than any ordinary cold in the head; with this there is not much discharge from the nose, but the patient complains that he can get little or no air, except through the mouth, this being accompanied with excessive oppression, much more than the condition would seem to warrant. This symptom was first called to my attention by my father, Dr. J. Forsyth Meigs, in a case we saw together nine years ago."

A second short notice which attracted my attention to this subject, I find in the March 10th number, 1883, of the *Brit. Med. Jour.*, by Andrew Clark, under the head of "Renal Inadequacy," by which he understands a very early incipient stage of Bright's disease. His words in relation to our subject, speaking of the several types of patients, are as follows: "They are a people, as a rule, who are always catching cold, and who, when they catch cold, come into the category of the first characteristic, namely, that they do not get rid of the cold; they are the people who without apparent reason and without other existing disease, get pneumonias, pleurisies, pericarditis, and the like." The remarks, gentlemen, I have to offer you on these two quotations are few, but in my opinion they are of the greatest practical importance. We see from the statements of these two men, that there must be some solid foundation in their descriptions, as they so essentially coincide. But of the full importance of this symptom, we only become aware when we reflect upon the enormous spreading and increase of Bright's disease at present in our own country; also on the fact, that the most distinguished clinicians, both in this country and

abroad, confess that in the whole nosology there is no disease of a more insidious beginning, and sometimes continued latently even to the rapid, quite unexpected end, than Bright's disease. This symptom, severe chronic coryza, I find not mentioned in any of our standard works; even Bartels, in Ziemssen's *Cyclo.*, who is a most close observer, and has made the study of kidney disease a lifetime specialty, does not speak of it; indeed, all we learn from our most trustworthy guides is, that we, in general, cannot even suspect the lurking enemy, until it is too late.

As in the present state of our science we are very far from a right interpretation of reliable premonitory symptoms of a good many dangerous diseases, but especially in Bright's disease with its very insidious beginning, each contribution of well-observed clinical facts to clear the diagnosis of this obscure subject, must be welcome, when it directs our attention to a conspicuous symptom which we so frequently meet, but which until now we were unable to interpret rightly. The more seems this to be the case in a disease, which, as we all too well know, must have reached at the present time an hitherto unheard-of extension, measured by the standard of advertisements of sure cures for kidney disease, which strike our eye in every newspaper of this country. It is a very plausible and ingenious remark, that the increase of this disastrous disease finds its explanation, for a greater part, in the manner of living our modern life, and on this point, gentlemen, allow me again to quote a short passage from Meigs.

"It cannot be proved by statistics, and yet I think there is strong ground for believing, that the proportion of deaths, caused by affections of the kidney, is greatly on the increase. The tendency of modern life seems to be such, that a larger number of deaths are caused by degenerative process, and less by acute disorders. In former times, children were less delicately reared, and a larger proportion of the frailer ones probably died from exposure and want of care; now beginning at childhood, and continuing up to old age, we are much more careful to avoid exposure, and more self-indulgent, at least as far as our bodies are concerned. Who, in modern times, except the professional athletes, would undertake the physical labors of the Emperor Charles V. of Germany, of whom Motley says, that he was able to tell, at a time when all journeys were on horseback, or by boat, 'of his nine expeditions into Germany, six to Spain, seven to Italy, four to France, ten to the Netherlands, two to England, as many to Africa, and of his eleven voyages by sea!' Nowadays, the majority of city men are in their places of business all day, and take but little exercise, eating as much and as rich food as in former times, and drinking not a little withal. The natural and necessary consequence follows, that after years of this kind of life, the excretory organs degenerate; first, the kidney, which is the common sewer of the body, and like the heart, has to do continual work from the hour of birth until the hour of death. It is a common thing, in

modern life, to see a man naturally robust and gifted with a large appetite, become more inert as years go by, when he will gradually give up his active exercise, until finally he takes none; still the eating and drinking go on, and he becomes fat and sluggish; finally he loses health, and then examination shows that degeneration is beginning in the kidney. I could instance several cases of the kind, but my space will not allow me."

My object in the presentation of this new subject, is to draw the attention of the Association to the study of this symptom in relation to Bright's disease, so as to give it its proper place in the symptomatology of the latter malady, as by keeping it in view, we might in many cases where, according to our two above-mentioned authors, it seems to belong to the early and curable stage of this later on becoming quite hopeless disease, be able to save many a valuable life, and so become true benefactors to mankind.

It needs the observance of a great number of searchers, as the field of one man, be it ever so varied, is too limited to make it fruitful for the profession at large.

I request you, therefore, not to lose sight of this symptom in your practice, and to report your experience at our next meeting; for, as you well know, to promote the science of medicine, we must not only be devoted students and close observers, but we must also learn to draw logical conclusions from our observations, and give them the right place in the nosology.

My own experience on this subject is, at present, too limited to speak with great confidence, but I can adduce at least one case, which I have had under observation for some time, which fully proves the correctness of this statement; and two others, to which my attention but lately has been directed, seem to point to the same deduction.

To impress upon you once more the importance of my subject, I will close it with one of the summary paragraphs, as stated by Meigs, "That severe coryza is a complication or accompaniment of Bright's disease, and has a diagnostic value."

Scarlet Fever: A Remarkable Series of Cases, and a Noteworthy End of It.

Dr. E. Diver makes this interesting report in the *Lancet*, January 19, 1884:

On November 21, 1880, my attention as medical attendant to a school of about 250 children was called to a girl with a rash, which I found to be that of scarlet fever. No information was forthcoming as to whence she got the disease. She was removed to the infirmary—a building in all ways isolated from the school; the room in which she had been temporarily placed was scoured and cleansed, and a good lookout amongst the children was kept up. In ten days another girl had scarlatina, and she was removed to the companionship of the former. Three weeks passed with no fresh case, but on the twenty-fifth day another girl had to be taken to the infirmary. We were free again until the twentieth day, when another girl showed signs of scarlatina, and was removed like the three others. In seventeen days more, three cases occurred together, all girls; in fifteen days from these, another girl; in twenty-eight days more, two girls; in ten days after these,

another two; and in twenty-three days more came the thirteenth girl, and the last of the series. After the tenth girl got ill, the disease showed itself in one of the boys, and I wondered whether we were now to have a regular epidemic. But time proved that this boy was the only one to be ill, and he turned out to be the brother of the sixth girl. It was proved, too, that his mother had seen and kissed him after having gained an interview with her convalescent daughter forty-two days after this girl's illness began. Ten days after the mother's visit, the boy complained of a sore throat. After each removal of a patient or patients to the infirmary, the interval was anxiously watched, and once or twice we began to think we had done with the disease. But on being disappointed, we were puzzled to account for its recurrence. There was no probability of infection from the old cases, and we knew of no scarlatina elsewhere in the neighborhood. The limited spread of the disease was against its being brought into the school with any sort of food, and all the water was pumped from a deep well. The drainage was almost entirely by earth closets, and there was no overcrowding, the dormitories being ample and well ventilated. At length I examined the water cisterns. These were situated in the roof of the building, and I traced each pipe going from them. One I found went to a dormitory, and terminated in a tap from which the girls on going to bed could draw water; and I ascertained that all the sick girls had drunk from this source; probably many others had done so, too. The overflow pipe from the same cistern had its orifice of discharge over a gully in the corner of a paved yard, the orifice being parallel with the gully, and an inch or two above it. Side by side with this pipe, and terminating at the same level, was another. This other led down from a slop sink, and conveyed the night urine from the girls' dormitory into the drain. These pipes had been in use for two years, as had the portion of the school wherein the disease occurred, and to which they belonged. The drain, which was trapped below the gully by a Doulton's siphon, conveyed also rain and bath-room water to the larger drain beyond, and the gully-grating was somewhat furred with urine salts. Now, whether the structural arrangement described had anything to do with the scarlatina or not, it was clearly a bad one, and open to grave suspicion. The overflow pipe was therefore cut away to half its length on March 26, 1881, nine days from the last case of illness, and was made to discharge itself upon a low roof hard by, thus dissociating it from the urine-pipe, which in its turn had its extremity cut into the shape of a jug spout. After this no case of fever happened.

Owing to the circumstance that no ordinary cause of the disease was discovered, as contagion or fomites, it seems probable that there was some less common cause for this series of cases of scarlatina. If so, either it was one of which I am not cognizant, or it was connected with the juxtaposition of the two pipes. In the latter case, the overflow pipe appears to have conveyed to the cistern, upon Tobin's principle of ventilation, air, with all that air may carry, and the chemical results of some decomposition of urine and perhaps other fluids; and by this contamination the water was made

equal to the production of scarlatina at uncertain intervals, depending partly upon the receptivity of those who drank of it. Arguing upon this, one's question next is, What is this chemical which was conveyed from the urine pipe, or perhaps, but unlikely, from the comparatively harmless drain below? For, so far as can be told, no ordinary scarlatina germs were present, the facts appearing to favor the theory that scarlet fever may be generated *de novo*.

As to the case of the boy, he had no means of getting at the water which the girls drank from, and I know of no way in which it was probable he took scarlatina, except it be admitted that his mother brought it to him. But if she did, the period of apparent incubation was of unusual length. It may be, however, that the poison lay in his clothing for a day or two, and so the ordinary period of incubation may not have been transgressed. But if the boy's mother did not bring the disease to him, and the girls did not get it by means of the pipes, then the facts given exemplify what is undoubtedly true sometimes, that with all the circumstances seeming to favor a given conclusion, that conclusion is not correct, because an important something else has needed recognition. Query: In the present case, is there this something else? And if there is, what is it? But if not, what was the seed of mischief in the water?

Auscultation of the Œsophagus.

The *London Med. Times*, January 19, 1884, says:

Attempts have frequently been made to establish some trustworthy means of diagnosing affections of the œsophagus and stomach by the aid of auscultation. The act of swallowing of necessity gives rise to certain sounds, and it is to the correct interpretation of these that we must look before making use of any modification of them in determining morbid conditions. A recent discussion upon the subject in the *Berliner Medicinische Gesellschaft*, introduced many points of interest, both from physiological and clinical points of view. The idea that deglutition is chiefly affected by means of the action of the constrictor muscles, and of the peristaltic movement of the œsophagus, has lately been opposed by a theory propounded by Kronecker and Meltzer, who divide the act into two parts, of which the first consists of the rapid injection of the masticated food or fluid through the œsophagus, and the second in the further injection of the food through the cardiac orifice by the contraction of the lower segment of the œsophagus itself. The act is a very rapid one. The every-day experience of the sensation of swallowing may certainly be held to corroborate this theory. Hot or irritant fluids invariably make themselves felt at the upper and lower parts of the œsophagus only, a result probably due to the fact that it is at these points that they are forcibly squeezed against the mucous membrane. If the theory is correct, it is there also that they remain for a few seconds at rest. The pathological appearances produced by corrosive irritants are likewise most marked at the same points. The sound produced by these two spasmodic movements, by which the food is thus "squirted," so to speak, down the œsophageal tube, may be dis-

tinctly heard on listening at the side of the ensiform cartilage. A first sound, coincident with the upper œsophageal contraction, is described as resembling that produced by discharging a syringe-full of air under water; the second, following it after an interval of about seven seconds, is said to be somewhat similar, but coarser in character, and corresponds with the opening of the cardiac orifice and the spasmodic injection of the food through it into the stomach. Unfortunately for the diagnostic value of these auscultatory signs, their occurrence is not absolutely constant in healthy persons, although present in a very large majority of the cases examined. Neither is there perfect agreement between individual observers as to the character and relative intensity of the sounds produced. Almost identical noises are heard over the stomach when the œsophagus is at rest, and they may even be set up by electrical stimuli. The subject is one which deserves attention, and especially in relation to affections of the œsophagus, which have, from the earliest days of medicine down to the case of the late Comte de Chambord, presented insurmountable difficulties to the most able diagnosticians; but until a standard can be determined to form a physiological starting-point, the efforts to interpret the auscultatory phenomena in the œsophagus will remain as futile as heretofore.

Calculi of the Pancreas.

To the Pathological Society of London (*Brit. Med. Jour.*, January 12, 1884), Dr. Norman Moore exhibited three specimens of calculus in the pancreatic duct.

1. A pancreas with a dilated duct, containing numerous irregular calculi of carbonate of lime. The duct was most dilated near the head. There were stones in all parts of it, but it was nowhere completely closed. The patient was a man, aged 40, who died of diabetes. The bile-duct was pervious, and there was never any jaundice.

2. A pancreas, with its main duct slightly dilated, and containing a calculus of irregular shape, around which was a large abscess in the head. This abscess pressed upon the orifice of the bile-duct sufficiently to produce great distension of the gall-bladder. The patient was a man, aged 43, who died in St. Bartholomew's Hospital of an attack of pleurisy following gouty symptoms.

3. A pancreas, with great dilatation of the duct throughout its length. Near the orifice the duct was blocked by a small calculus of irregular shape. The whole gland was very hard, and, to the naked eye, showed a great increase of connective tissue. The papilla in the duodenum was enlarged, and the hardened tissue of the pancreas had constricted the bile-duct, so as to cause complete obstruction. The liver was of a deep green color, intensely hard, and with general dilatation of its ducts, which everywhere contained watery bile and bile-gravel. The glands in the hilum of the liver showed no new growth, and a careful search showed none anywhere in the body. Microscopic sections of the pancreas showed an extensive increase of connective tissue. Many bands of old growth traversed the gland, and there were patches of nuclei of a more recent connective tis-

sue-growth. Some normal acini were visible, but in most, the gland cells were more or less atrophied. No cells like those of the acini were to be found beyond their proper limits, nor were there any other signs of carcinomatous growth. The morbid change was of the same kind as that found in the liver of cirrhosis. Dr. Wickham Legg had shown that dilatation of the hepatic ducts would produce a connective tissue increase throughout the liver. In this pancreas a gradual dilatation of its ducts, due to the occlusion of the main duct by the calculus, was probably the cause of the new connective tissue growth throughout the gland. Cirrhosis of the pancreas, as a result of calculus, had not, he believed, been described before. The patient was a man, aged 64, who was admitted to St. Bartholomew's Hospital in July, 1883, and died in October. He had been ill for a month, and jaundiced for three days on admission. His liver was not then enlarged, but on August 13th was distinctly increased in size. During his illness, he had many attacks of vomiting, but no colic. Dr. Moore had exhibited two specimens of abscess of the pancreas due to calculus, at this society in 1882, and this was the only one which had occurred since in the post-mortem room at St. Bartholomew's. In the three cases of pancreatic calculus now shown, there was jaundice in only the last, and colic in none; but, in all three, attacks of vomiting were noticeable clinical features.

Rupture of Intestine.

Dr. A. McLean reports this case in the *Brit. Med. Jour.*, February 9, 1884:

W. H., aged 32, fell from a tree, a distance of twenty feet, on December 24, 1883, about four o'clock in the afternoon. He had dined at one o'clock. He fell flat on the body, and was found by those who went to his assistance lying on his belly. With help, he walked two hundred yards to a truck, on which he was taken home. He did not lose consciousness. When seen at 5 p. m., he was suffering from pain, chiefly over the region of the bladder, in the left groin, and in the right flank. There was an abrasion of the right elbow, and his lips were cut. There was very little shock. He said that he wanted to pass urine, but could not do so; he had passed urine before ascending the tree. A catheter was passed, and about a pint of clear straw-colored urine withdrawn. He was ordered to have thirty drops of tincture of opium every three hours, and ice and milk. At 7 p. m., he was found lying over the edge of the bed vomiting, and had thrown up his dinner partially digested, and containing a few clots of rather bright-colored blood. As he had a good deal of abdominal pain, a quarter of a grain of morphia was given subcutaneously, and a bran poultice applied to the abdomen. The temperature was 99°; the pulse was rather frequent and hard. He could take a deep inspiration, which caused pain only in the right flank. At 10 p. m., he had expectorated some mucus tinged with blood, but had no further vomiting. He could bear firm pressure all over the abdomen, but there was tenderness in the left groin. About three ounces of clear urine was drawn off by the

catheter. Temperature, 100.6°; pulse, 100; respiration, 24; he was very cheerful.

December 25, 11 a. m. He said he felt comfortable. He could bear firm pressure on the abdomen; there was tenderness in the right flank and left groin. Half a pint of strong-smelling dark brown urine was withdrawn by the catheter. He was ordered to continue the opium-mixture, milk, and ice. Temperature, 100.2°; pulse, 93; respirations, 26; his breathing was shallow, but he could take a deep breath. At 5 p. m., there was no change in the breathing; half a pint of urine was withdrawn by the catheter; the abdomen was rather distended and resonant; pain was not increased. I left him feeling comfortable and cheerful. I did not see him again, but was told that about 10 p. m. he complained of pain in the abdomen for about an hour, and then was easier. He was cheerful and comfortable up to 3 a. m., when, after a few deep inspirations, he died.

Post-mortem examination thirty-seven hours after death. The abdomen was distended and discolored; there was considerable peritonitis, with lymph very thick in patches on the small intestine in the left iliac region; much congestion of the intestine, which was ruptured at about the junction of the ileum and jejunum, opposite its mesenteric attachment; the rent would admit the introduction of three fingers. There was no other lesion. In evidence given at the inquest, it came out that a piece of wood about three inches by five inches was found under the body of the man; this would probably account for the rupture.

A Case of Mistaken Sex.

Dr. Wm. P. McGuire reports this case in the *Med. News*, February 16, 1884:

A B., thirty-five years of age and in good circumstances in life, consulted me on January 12, 1884, in order to have the sex to which she belonged determined. She was, to all outside appearances, a fairly-formed woman about five feet four inches in height, with long hair curling down her back. Her voice and features were effeminate, and her demeanor was modest. From birth her dress had been that of a woman. All of her associations had been with women, and her business in life that usually followed by that sex. There was no hair upon her face.

I found upon examination that the conformation of her thorax was similar to that of a woman, and that her breasts were developed similarly to those of a young girl. The nipple was erectile. Her arms, hands, and lower limbs were those of a man. There was a small penis in the natural position about three-quarters of an inch in length, with a well-formed glans and prepuce. It was capable of erection, but had in the glans no aperture. Following from the base of the penis backwards was a sulcus about one-half an inch in depth and two and a half inches in length. Lying upon each side of this sulcus, and each enclosed in separate scrotums, were two well-formed and developed testicles, each attached to a moderate-sized spermatic cord, the whole conformation resembling the vulva of the female. There was no opening in this sulcus, but just at its posterior termination was an opening one-quarter of an inch in diameter, which was the external opening of

the urethra, extending backwards and upwards into the bladder. No prostate gland was found. She stated that all of her proclivities and desires had been masculine, and admitted that occasionally in her sleep she had pleasurable sensations, followed by an ejaculation of a white fluid from the opening of the urethra, which was, of course, an ejaculation of semen. There was no trouble in determining her sex. She was advised to change her dress to that of a man, and to attempt to have by a plastic operation a new urethra made from its termination in the perineum, along the sulcus to the glans penis, in order to effect more convenient urination, as she is now obliged to do so in the sitting posture.

REVIEWS AND BOOK NOTICES.

BOOK NOTICES.

Medical Annals of Baltimore from 1608 to 1880.

By John R. Quinan, M. D. Paper, 8vo., pp. 275. Price \$1.00.

In a very painstaking manner the author of this volume has collected everything of interest about the profession in the city of Baltimore, and deserves great credit for his labors. It was prepared by request of the Medical and Surgical Faculty of Maryland, as a memorial volume, in honor of the Sesqui-Centennial of Baltimore, October, 1880. It comprises:

1. A chronology of events connected with the progress of medicine in Baltimore from 1608 to 1880.
2. A biography of Baltimore physicians, to which is appended a record of their literary contributions.
3. A subject-index to the literature.
4. A record of public services, military, civil, and medical, performed by Baltimore physicians from 1608 to 1880, in the city, state, and national governments, with statistics of the charitable and public institutions of Baltimore.

It is of interest not merely to the physicians of Baltimore themselves, but to their families and descendants.

Orders, enclosing the required amount, sent to the librarian, Dr. E. F. Cordell, 122 West Fayette street Baltimore, will be filled as soon as received.

Contagious and Infectious Diseases: Measures for their Prevention and Arrest. Small-pox, Variola; Modified Small-pox, Varioloid; Chicken-pox, Varicella; Cow-pox, Variola-vaccinæ; Vaccination; Spurious Vaccination, etc. By Joseph Jones, M. D. Baton Rouge, 1884.

This closely-printed work of 410 pages, is characterized by the usual thorough method of its author. His extensive reading and enthusiasm of

investigation appear on every page. The history and pathology of the class of diseases of which he treats have never been more exhaustively handled. Several very rare early tracts on vaccination are reprinted in full. The unfortunate results of many of the vaccinations during the civil war are noted and explained. The relations of syphilis to vaccination are stated, and many alleged cases are critically examined. In discussing the relative merits of humanized and bovine virus, the merits and disadvantages of each are fairly and fully stated. As a hand-book of reference on these allied topics, it is the most complete we have seen. For copies, address the author, New Orleans, La., as it is an official publication of the State Board of Health.

The Relation of Animal Diseases to the Public Health, and Their Prevention. By Frank S. Billings, D. V. S. 8vo., pp. 448. D. Appleton & Co., New York.

This volume is divided into three parts, the first of which treats of the nature and prevention of various diseases of domestic animals, especially trichiniasis, hog cholera, tuberculosis of cattle, anthrax, and glanders. The author does not discuss the treatment, but the prophylaxis only. The second part is on the history of veterinary medicine; the third on veterinary education.

While the writer is evidently well acquainted with his subject, he fails to present it in an agreeable manner. Although his preface intimates that his volume is addressed to the educated public, it is filled with the most elaborately long and learned technical terms. What sort of a sentence is the following for a popular treatise: "If a trauma formed the atrium of the inficiens, we may remark on the locus infectionis hyperæmia and inflammation!!" Yet there are hundreds of passages just as pedantic as this.

His remarks on medical education, which he goes out of his way to criticize, are dogmatic in the extreme, especially for one who is not himself an M. D. He has a plan to shut up all the medical colleges in the country, and open one for free medical education at the public expense! There is a disease which they call out West "the big head," from which the writer seems to suffer.

—Wigglesworth defines mania as a disease involving disorder of the relational elements of mind, and of a greater or less number of these, according to the intensity of the disease; in other words, what we clinically know as mania has for its material substratum an affection, functional or organic, of the higher co-ordinating plexuses of the brain.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D., }
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

The COMPENDIUM, formerly published every six months, appears now *every three months*. It is compiled with special reference to being taken with *the Reporter*, and none of the articles which appear in our weekly are reproduced in our quarterly publication. It is made up exclusively from other sources.

Each number of the *Quarterly Compendium* contains 150 pages of reading matter, carefully selected from American, British, and European medical journals, with a special view to the wants of the American physician. It is on excellent paper, and neatly bound in pamphlet form, with full table of contents and index.

The price of the COMPENDIUM is 75 cents a number, or \$2.50 a year; and it will be found well worth it. But when taken with the REPORTER, we offer the two journals at the very low price of SIX DOLLARS, when paid for *strictly in advance* and directly to this office.

A SUGGESTION ON MEDICAL EDUCATION.

That there are more doctors to the population in the United States than anywhere else, is a matter of common knowledge and public statistics; that, on the whole, these doctors are the worst educated of any in the world, is a truth which those who are in a position to judge will concede, and which might be assumed from what everybody knows of the facility of obtaining degrees, or of the slight necessity of obtaining them at all.

The result of this might be expected to be that the community at large would begin to lose its faith in doctors. But not so, thinks an enterprising writer on this subject, Dr. Alexander Hutchins, of Brooklyn.* He maintains that in spite of such facts—that an important daily paper openly asserts that “expert testimony no longer occupies the place in public esteem it once held,” when a well-known lawyer charges in open court that “you could buy the most honorable members of the medical profession as you could horses in the open market,” and when a judge passes by the claims of the alienists and appoints a dermatologist and a gynecologist as a commission to examine a man on a lunacy writ—yet the fact still holds that the attitude of the community to the profession is eminently docile and receptive.

All legislation worth obtaining can be obtained; the family physician is as much a power in the household as ever; and the gullible public puts down its gullet about eighty million dollars' worth of quack medicine, and as much more of the authentic stuff annually, all on the faith of what it thinks is “medical advice.”

Nevertheless, he warns us that this happy state of feeling may not be perennial. Some demon may whisper doubts in the public's long ears, and then it will behoove the doctors to be on the watch. It may be prudent that they have an education befitting their position, and Dr. Hutchins' suggestion impresses us as a wise and a timely one. It is very simple, and we give it in his own words:

* *The Reciprocal Attitude of the Medical Profession and the Community. The Anniversary Address before the Medical Society of the State of New York, February, 1884.*

"One may be justified in parting company with the practice of the period, and demand, in the interest of medical science, for the purity of medical art, for the maintenance of professional honor, and for the protection of the community, that the teaching and degree-granting authorities be *not* one and the same. Let the community, through its law-makers, legislate into control an acceptable judicial body, in which shall rest the decision of the fitness of candidates to assume the responsibilities, enjoy the honors, and reap the emoluments of professional life, and the sharp contests of dogmatic rivalry, the destructive wiles of medical harpies, and the weakening competition of medical schools, would be rapidly equalized in the 'survival of the fittest.' Fitness is, in some sense, a test of honesty, and this safeguard the community has a right to demand."

This may not be entirely new; it is not without precedent; and so much the better. We commend it as a sound plan, worth adopting in every State, which in the simplest manner possible would regulate the whole question of medical education.

NEUROSES OF THE VISCERA.

We are oftentimes called upon to treat cases that puzzle us very much, since it seems very difficult to account for the symptoms that present themselves, by reasoning upon any of the ordinarily taught doctrines of pathology. We will, for instance, be confronted with a patient who offers many of the symptoms of serious disease of the stomach, or of the bowels, or of the kidney, liver, or bladder, and yet upon careful physical examination we fail to detect any organic disease, and in time these trying symptoms vanish, and the patient complains of them no more.

Such cases are very trying to the physician, because he is at a loss to account for them, when, upon examination, he utterly fails to elicit the evidence of such pathological conditions as would suggest their *raison d'être*.

Some time ago we referred to a condition of excessive pulsation of the abdominal aorta, noted more especially in women, which had oftentimes given rise to the suspicion of aneurism, when in reality there was no diseased condition present, the trouble being altogether functional, and nearly allied to what is best described as nervous

palpitation of the heart. Dr. Clifford Allbutt (in this year's Gulstonian lectures) leads us further on in this direction, and describes what he is pleased to term the "*neuroses of the viscera*," which, while purely functional, yet generally simulate grave organic disease of the organ affected. Gastralgia, enteralgia, nephralgia, are all conditions allied to neuralgia of any other portion of the body, and yet so little written about that we are puzzled when a case comes to our notice. Ordinary neuralgia of the face is sometimes so severe, to use a homely phrase, that the whole system sympathizes, and for a time the afflicted person is really very sick, though there may be no organic disease; so with neuralgia of the stomach, of the bowels, of the kidney, or the liver, we may have the same reflex phenomena. The important practical lesson to be drawn from Dr. Allbutt's excellent lectures is that when we have a train of symptoms, apparently emanating from some organ, which, upon examination, we find to be healthy, we are to look upon it as a neurosis or a functional nervous derangement, due to some condition for which we must search. It may be a depraved condition of the general health, or it may be due to psychical causes, as mental depression from one cause or another; but whatever may be the cause, we must find it out and remove it, else we will continue to be puzzled by these *feigned* organic diseases.

THE MEDICAL ASPECTS OF SEA VOYAGES.

The English medical journals have been lately saying a good deal on the question of life at sea from a medical standpoint, both sides of the question, as is usual on almost all questions, having its advocates. There are some who claim that sailors are not particularly long-lived men, and hence they argue that sea-life is not particularly conducive to health. Their opponents point to the proverbially-reckless life of sailors when on shore, which they very justly argue is well calculated to counteract the benefits to health that are conferred by sea voyages. Again, the discomforts sometimes experienced on vessels are used as ar-

guments against the advocacy of this therapeutic resource. The truth seems to lie in a careful consideration of the cases that are likely to be benefited by sea voyages and the reverse. There can be no doubt that sea air is to most persons a tonic, and a most potent one; while it is equally recognized that to some it acts in just the opposite way. When a man, extensively engaged in business pursuits, is run down by too close application, mentally and physically, to his business, there cannot be devised a better tonic than a sea voyage; for not only is he exposed to the constant inhalation of a pure, bracing, and tonic atmosphere, but by the very isolation which it entails, his mind is relieved of its business worries, while each day brings with it merely another period of repose and quietude in lieu of the renewed business anxieties engendered by each new day at home. Even the busiest men are willing to be lazy and idle when under the subtle influence of a sea atmosphere, and day succeeds day in blissful and rejuvenating idleness. To the jaded and over-worked body and mind, a few days at sea will prove far more efficacious than all the drug tonics in the world.

NOTES AND COMMENTS.

Ulceration of Bowel, with Copious Hemorrhage, Cured by Castor Oil.

Dr. Hildyard Rogers reports this case in the *Brit. Med. Jour.*, February 16, 1884:

Miss G., aged twenty-eight, was first seen on March 22, 1883. She had been suffering since the beginning of March from diarrhœa, accompanied by hemorrhage. Her father, mother, one sister, and one brother, are living and healthy. One brother died, at adult age, of phthisis. She was looking plump and well nourished, and had no pain. The tongue was clean, but red. Nothing abnormal could be made out on abdominal palpation. The heart and lungs were sound. There was no cough. The urine was normal. The rectum was slightly dilated. She had internal piles, which had bled occasionally, but not to any extent. She had always been regular and healthy. She had, since the beginning of March, been passing daily two or three loose motions, containing shreds of mucus and dark clots of blood.

Temperature (morning), 101.3° Fahr.; pulse, 120. Between March 22 and May 9, the diarrhœa steadily increased in severity, and the blood changed from dark clots to a bright arterial color. At the latter date, the motions consisted apparently of little else than blood and mucus, and the bowels were acting ten or twelve times in the twenty-four hours. There was at times troublesome vomiting, and steady loss of flesh, but never during the course of the illness any pain, other than that arising from bed-sores and from the patient's general weakness. The most careful examination, as well as the character of the motions, showed that the blood did not come from the internal piles, or from the lower part of the bowel. The temperature ran an irregular zigzag course, rising at times as high as 103.4° Fahr. The pulse seldom varied, and was nearly always soft, compressible, 120 to the minute. There was never any tympanitis.

During this period (seven weeks prior to May 9) she was seen in consultation with Dr. Ogle, Dr. Bird, and the late Dr. Hilton Fagge, all of whom concurred in the diagnosis. Opium, belladonna, bismuth, cerium, logwood, nitrate of silver, etc., were found utterly useless. Suppositories and injections of various kinds were tried without avail. By May 9, she was reduced to a very emaciated condition, and was too weak to turn in bed. Food was taken with great difficulty, owing to the constant vomiting, and the patient's condition appeared almost hopeless. On May 9, she was seen by Dr. Gibson, of Newcastle, at whose suggestion drachm doses of castor oil each day were tried. Within twenty-four hours after taking the first dose, she passed a feculent motion. The castor oil was repeated eight times up to May 20, and after this only occasionally. The temperature fell in forty-eight hours from 103° Fahr. to 99° Fahr., and never rose again above 100° Fahr. The diarrhœa rapidly abated, the stools becoming feculent and healthy. No blood was passed after May 18. The patient rapidly regained flesh and strength, and, although bearing traces of the severe illness and physiological starvation which she had undergone, was able to go to the sea-side in July. In September, a slight relapse took place, but was easily cured by the same treatment; since that time, the patient has remained in good health.

Foot and Mouth Disease in Human Beings.

A very remarkable epidemic of aphthous sore throat has occurred in Dover, England, recently,

and so far it seems to have been connected with foot-and-mouth disease in a dairy. The outbreak has been very carefully investigated by Dr. Robinson, medical officer of health; and though his inquiries are not yet completed, he has laid a report on the subject before the Town Council. From the first, suspicion attached to a certain dairy in the town, but it soon became evident that all the milk sold there was not implicated. The dairyman, however, received milk from other dairy farms than his own; and at one of these, situated in the country, it was found that the cows had suffered from foot-and-mouth disease. Not only so, but amongst the customers of the Dover dairyman those who partook of cream alone were especially affected; and it transpired that the only cream sold at the Dover establishment was that received from the country dairy alluded to. Another circumstance connected with this dairy was that some fourteen persons who did not obtain milk from the Dover dairyman, but who had their supply from the affiliated country dairy, were affected. In all, we hear of 144 attacks; 130 receiving their milk from the Dover establishment directly. The special influence of cream, as conveying the *materies morbi*, was shown by the fact that the proportion of attacks in adults, as compared with children, was large, and many adults who took no milk had partaken of cream in their tea—some indeed doing so at the houses of friends on a single occasion only. The symptoms of the sufferers were shivering, followed by headache and fever, pains in the limbs, parched lips, and a vesicular eruption on the throat. In some cases the tonsils were enlarged, and in others they suppurated, the process being accompanied by enlargement of the glands. As already stated, the inquiry is not completed, and we are promised a further report from Dr. Robinson. When this is received, we shall doubtless be able to learn the precise proportion of attacks to persons using the implicated milk and cream, as also the number attacked in the town. That some should be attacked who did not partake of the milk, in no way invalidates the theory as to the source of the infection. We expect it will be shown that in such attacks personal infection may have come into operation, and that they were secondary cases, this question being essentially one of dates. That the milk of cows suffering from foot-and-mouth disease is capable of producing some definite affection in the human subject, has often been shown; but never, so far as we are aware, has there been an outbreak on so large a scale as that which is being investigated by Dr.

Robinson. The occurrence is therefore one which has very special interest both to the medical and the veterinary professions.

Persistent Flaccidity of Uterus after Labor.

To a recent meeting of the New York Obstetrical Society (*N. Y. Med. Jour.*, April 5, 1884), Dr. Perry related the case of a lady, thirty-eight years of age, the mother of five children, the youngest being four years old. She had complained, since the birth of this youngest child, of bearing-down pain and inability to stand or walk, from the great pressure and weight in the pelvis. Menstruation occurred every three weeks, and lasted, with scanty flow, seven and eight days. On making a vaginal examination, he found the cervix in its proper position, but very short and flaccid, and, extending around it in a circular direction, a soft mass, apparently the result of a pelvic inflammation. On conjoined manipulation, the mass appeared very shallow, but nowhere could he find the fundus of the uterus. A sound was introduced, which penetrated but two inches. Not doubting that it was within the uterine canal, he essayed a little force, and with this was able to penetrate to the depth of eight inches, and, while doing so, found that the mass in the pelvis disappeared. He had, indeed, while forcing the sound upward, carried the uterine wall before it. An electrode was substituted for the sound, and a current of galvanism conveyed to the endometrium. This was done from day to day, without, at first, eliciting more than a slight flow of blood; but in time contractions followed, and finally sufficient firmness was established to justify the use of a vaginal support. At this juncture ergot and galvanism were used together, and a complete cure was eventually established. The patient had since become pregnant, and promised to do well. Dr. Perry thought this a case of subinvolution resulting from sudden and complete cessation of contraction after labor, leaving the uterus in a state of collapse; but he thought some might regard it as essentially a case of paralysis.

The Treatment of Orchitis.

Dr. H. M. Lawson recommends the following simple plan in the *Southern Med. Record*, March 20, 1884:

Take a piece of cheap, thin homespun, about three and a half inches long and three-fourths of an inch wide; double it the long way and sew the edges together; then fill with cotton, not too tightly, sew a button on one end and make a button-hole in the other; this, when buttoned, will

form a ring. All that is necessary in addition to this is a piece of the same kind of homespun four inches square. Apply as follows: Put the centre of the square piece of cloth to the centre of the swollen testicle below, bring the edges and corners up around, completely inclosing it, then button the ring around above the testicle, which will hold it in position. Now draw upon the edges and corners of the square piece all around until sufficient compression is made. The sound testicle is to be left above the ring.

If too much compression is made, it is easily removed by drawing the cloth in the opposite direction: it is easily increased or diminished at will. Its other advantage will be apparent on using it. Easily obtained, applied, and adjusted, I feel sure that no one who tries this method will afterward use any other.

Septic Pneumonia of Children.

In the *Deutsch. Arch. für Klin. Med.*, December, 1883, Silbermann publishes an article on this subject which thus concludes:

1. The septic pneumonia of infants and nursing children, and which begins as a tracheo-bronchitis, is a catarrhal, and very often a foreign-body pneumonia.

2. It begins by the aspiration of decomposing amniotic fluid and genital secretions, or by the inspiration of strongly-infected air from some septic disease of the mother.

3. Septic pneumonia of infants frequently accompanies diseases of the pleura, but seldom of other organs.

4. The alveoli and bronchi of the lungs of children dead of septic pneumonia are filled with bacteria.

5. The blood shows an increased amount of white globules, and a broken-down condition of the red.

6. Icterus is not a constant accompaniment of the disease.

7. The time at which the disease occurs is from one to two days after birth, and death usually takes place in about two days.

Hydrops Amnii and Change in Presentation.

Dr. N. O. D. Parks, of Ashton, R. I., writes to the *Med. Record* that he was called to attend a woman who had been in labor for over twelve hours. The pains were feeble, but after some hours improved. Examination showed a head presentation, os well dilated. The pains then ceased again, and the patient got up and walked

around. There was evidently a very large amount of liquor amnii, though the membranes were not ruptured. When the pains returned, examination showed that the foot was presenting instead of the head. Dr. Parks quickly ruptured the membranes and seized the foot, but found it hooked over the head. He finally disengaged it, and completed the delivery. "The points of interest in this case," continues Dr. Parks, "are the rapid and alarming change of presentation, and the difficulty in delivery arising from the foot becoming hooked around the child's neck. The fœtus had evidently been floating about in more than a gallon of liquor amnii, and constantly changing its position; and the lesson I would derive is in every case of hydrops amnii to rupture the membranes the moment you get a favorable presentation, without waiting for a pain, irrespective of the condition of the os."

Creasote Poisoning.

The *London Med. Record*, December 15, 1883, says that Dr. Pürckhauer (*Friedrich's Blätter für Gerichl. Med.*, 1882, p. 430) publishes an elaborate account of a fatal case of creasote poisoning, with the remark that only two cases of poisoning by creasote have previously been recorded—one by Müller (*Würtemb. Correspondenzblatt*, Band xxxix., No. 42, 1869), the other by the writer of this notice (*Guy's Hosp. Rep.*, 1875, p. 44), a non-fatal case. In Pürckhauer's case, a child ten days old received, as was computed, 24 to 30 drops of undiluted creasote. The symptoms were developed almost immediately, and were very like those produced by carbolic acid; injection and inflammation of all visible parts with which the poison came into contact, salivation, extremely contracted pupils, difficult respiration, imperceptible pulse, coldness of the extremities, profound coma, and loss of reflex activity. The child did not regain sensibility, was convulsed, and died sixteen hours after the administration of the poison. The necropsy showed lesions similar to those following the administration of carbolic acid—corrosion, local inflammation of the alimentary canal, dark blood, injection of the capillaries, and an all-pervading odor of creasote throughout the body.

Cold and Position in Strangulated Hernia.

With the view of demonstrating the advantages to be derived from a combination of these two resources, Dr. Geo. C. Kingsbury thus writes to the *Brit. Med. Jour.*, March 15, 1884:

I have recently had two cases of strangulated

hernia; both were severe, and had lasted many hours.

In the first, taxis, warm bath, opium, and chloroform had been tried without effect; the patient had begun to vomit. The foot of the bed was now raised high enough to rest on an ordinary chair, and an India rubber bag full of ice was placed over the tumor. After waiting an hour, taxis was again tried, and the tumor had scarcely been grasped when it began to yield, and the bowel was readily returned.

My second patient had the misfortune to be drunk, when he ruptured himself during a wrestling match. It was not until the next morning that he discovered his condition; and even then, not knowing exactly what was amiss, he waited to try if a dose of castor oil would cure him. In this case, simple taxis having failed, I at once adopted the same measures as before, and, in about three-quarters of an hour, was able to reduce the hernia with ease.

Sponge-Grafting of Sinuses.

Who has not had his patience severely tried by obstinate sinuses that would not heal, do what he might? For such, Dr. W. Winslow Hall casts a ray of light into the darkness, when he tells (*Edinburgh Med. Jour.*, March, 1884,) of an obstinate case which he has cured. There were several sinuses on the forearm, lined with a tough, dense membrane, which would not heal properly, notwithstanding that he injected stimulating lotions, laid them open and resorted to all the usual devices. Finally, he hit upon the idea of sponge-grafting, which he thus carried out. A strip of fine sponge, one and a half inches by a quarter inch, had been soaked in dilute nitro-muriatic acid for twenty-four hours, then washed in water, soaked in carbolic solution for twenty-four hours, and washed a second time in water. This was tied to a piece of thin catgut threaded on a long needle. A director was thrust to the bottom of the sinus; the point of the needle was passed down to the end of the director, and was then brought through the skin. The director was withdrawn, and by pulling on the needle and catgut the sponge-strip was made to fill the sinus from top to bottom. The catgut thread was cut off at the level of the skin, and the wound was dressed with carbolic oil.

Some months afterwards, the patient reappeared at the hospital to show his arm. There was a small pliable cicatrix, but otherwise the limb would have been taken for a normal one.

Post-partum Prolapse of Vagina.

Such a case as Dr. Blenkarne reports in the *Brit. Med. Jour.*, March 22, 1884, is by no means usual. After the birth of the child he found a semi-globular protrusion, about the size of the upper part of a six-months fetus's head, the surface shining, and of a dull reddish color, not looking at all unlike a foetal head covered by the amnion. On further examination he found that there was continuity of tissue between this protrusion and the external parts of the mother, that is, of the left buttock. The uterus was in its normal position and well contracted, and there was scarcely any hemorrhage. The urethra seemed pulled out of position, for, on attempting to pass a silver catheter, he could not pass it beyond three-quarters of an inch or so, and it appeared as if that passage were bent upon itself. The rectum was in its normal position. Upon attempting reduction of the tumor, he found that he was unable to do so to any great extent. He attempted taxis, and after some trouble (and without giving chloroform), the tumor, at least the greater part of it, was reduced.

Resection of the Lung: An Old Operation.

It would truly seem that there is really nothing new under the sun, for Dr. Bonfigli sends to the *Gazzetta degli Ospitali* a curious and interesting case that he has extracted from an old medical author, Nicholas Tulpius, of Amsterdam. A piece of lung about three fingers' breadth protruded through a large wound under the left nipple. The wound was altogether neglected for at least two days. The protruded portion of the organ then being found dead, was ligatured, and was cut off with scissors. It weighed about three ounces. The wound healed within a fortnight, with the viscus united to it, the latter point being verified six years later by section of the parts. Celsus and Hippocrates are quoted in support of the treatment adopted. Touching this case, it is of interest to remark that Dr. Biondi, from his experiments on animals, concludes that the removal of a lobe or the whole of a lung is, in a great number of animals, well borne. The operation in the human subject, however, performed three times lately with a view to cure (twice by Ruggi, of Bologna; once by Block), has as yet had only a fatal issue.

A Rare Form of Laryngeal Neurosis.

Although the condition to which Dr. P. McBride refers in the *Edin. Med. Jour.*, for March, 1884, is not particularly new, since it was described by Char-

cot in 1876, it is yet sufficiently rare to deserve notice. The condition can best be described by quoting one of Charcot's cases. A patient, who complained of gout and cough, but was certainly not epileptic, was from time to time, after a slight cough, affected by vertigo without loss of consciousness. During these attacks he fell down, without a trace of convulsive movement, but very soon recovered, and got up. These seizures were first noticed when the cough began. The attacks may vary in frequency and intensity, consciousness being sometimes absolutely lost. After discussing the mechanism of these attacks, Dr. McBride comforts us by stating that the prognosis is very favorable, since only one death has been recorded, and that the disease is very amenable to treatment, which we presume would consist in removing any local cause of irritation that might exist, or in allaying the excessive irritability of the laryngeal nerves by suitable means.

Topical Cardiac Blistering in the Treatment of Acute Rheumatism.

Dr. Neil O'Donnell Parks recently told the Rhode Island Medical Society (*Med. News*, April 5, 1884,) that he had employed this mode of treatment in seven cases, and in one of them no other measures whatever were used; the result being in this, as in the other cases, a prompt and complete cure. In the remaining cases, salicyn, or one of its allied compounds, and ammonium carbonate, were given internally. Oleum gaultheriæ was used in some instances—internally in doses of fifteen drops once in two hours, and applied locally to the inflamed joints, combined with an equal amount of lin. camphoræ comp. The series described included cases of acute articular rheumatism, and rheumatic gout, so-called. In some of the cases an endocardial murmur was present. Usually, one blistering sufficed, but in case of relapse it was repeated. The writer expressed his belief that we have, in the method under consideration, the most valuable adjunct to our means of successfully treating rheumatism.

The Treatment of Ruptured Perineum by Iodoform.

The *London Med. Times*, February 23, 1884, says that a recent number of the *Zeitschrift für Geburtshülfe und Gynäkologie* contains an article by Dr. C. Behm, on the above subject. He points out that in the region of the vagina and perineum the efficient application of the ordinary kinds of antiseptic dressing is very difficult, if not impracticable, on account of the unavoidable fouling of them

by urine and feces. Iodoform has the property of closely adhering to wound surfaces, over which it forms a felt-like covering, difficult of detachment. It is, therefore, peculiarly suited to the needs of the ano-vulvar region. The method which Dr. Behm recommends, is the painting the surface of the wound with "iodoform-collodium" (iodoform one part, flexible collodium ten parts). He believes that the protective film thus formed does not act as a foreign body, and prevent primary union, but that, on the contrary, by checking secretion, it favors this mode of healing.

The Reality of Gastralgia.

Speaking of neurosis of the viscera, Dr. Clifford Allbutt, in the *Brit. Med. Jour.*, March 22, 1884, argues strongly in favor of the reality of gastralgia, instead of considering it as an hysterical manifestation, and after citing many good reasons for his belief, concludes thus:

"And now, gentlemen, have I succeeded in enforcing that which you already know—namely, that all the symptoms I have discussed to-day form, not only a consistent, but a very uniform series? Few maladies present a more definite series, or one more capable of rational explanation. Is it not one of the last maladies to be classed with those of irregular, capricious, and fanciful evolution? Shall we then say, as the authors of our text-books do to this moment, that gastralgia is, for the most part, a malady of hysterical woman?

Calcium Sulphide in Diabetes Mellitus.

The variety of drugs that have been recommended for the cure of this very imperfectly understood disease, offers strong presumptive evidence of the inutility of them all. However, we must record what seems worthy on the subject. Dr. C. M. Cauldwell (*N. Y. Med. Jour.*, April 5, 1884), has used calcium sulphide in three cases; in one it produced no effect whatever, in the others improvement began and recovery took place during the administration of the remedy. The dose is $\frac{1}{4}$ to $\frac{1}{2}$ grain three to five times daily. Dr. C. concludes that although calcium sulphide is certainly not a specific in diabetes, yet it seems worthy of a trial in persistent cases of this distressing disease.

A Noteworthy Umbilical Hernia.

In the *Brit. Med. Jour.*, March 22, 1884, Dr. Trevor Fowler reports a case of operation for um-

bilical hernia which possesses the following points of interest:

1. The recovery of a patient, at the advanced age of sixty-eight, from so serious an operation.
2. The radical cure of the hernia, which appears to have been accomplished by inflammatory adhesions about the neck of the sac sealing up the ring, which then became consolidated by granulation and contraction of the wound.
3. The illustration which the case affords of the value of pushing opium, and of the absolute safety with which this may be done, provided it be only given, as here, in small doses at a time, at frequent intervals, and with strict injunctions to the nurse that the patient is never to be awakened for his dose.

An Anodyne Mixture Without Opium.

R. Chloroform,	.100
Ether. sulphur. spts.,	.025
Tinct. cannabis,	.175
Acid. hydrocyan. dil.,	.030
Hyosciamia,	q. s.
Ol. menth. piperit.,	.003
Tinct. capsici,	.003
Alcohol, 95 per cent.,	.350
Glycerine,	ad. 1.000
Dose, 10-30m.	

Dr. A. P. Meylert writes to the *Med. Record* that it has given him no little anxiety to find a suitable anodyne for patients cured of the opium habit. In attacks of intestinal colic or neuralgia, to which they are subject, any preparation containing morphia is necessarily excluded, since it would at once bring back the old habit. The above formula is the result of various experiments, and has been used with good results in his cases. Perhaps its publication may lead others to relate their experience likewise.

Gun-shot Wound in a Child of Eight Months.

Dr. E. B. Ward, of Greensboro, Ala., sends to the *Med. Record*, April 5, 1884, the history of a peculiar case of gun-shot injury. An infant of eight months was accidentally shot in the forearm, a charge of bird-shot lacerating the extensors, splintering the bones and elbow-joint. The infant recovered from the shock. Twenty-four hours after the injury, Dr. Ward amputated the arm just above the elbow. The operation had to be performed without intelligent assistance, but the patient made an excellent and rapid recovery.

—Dr. Sig. Friedmann reports the successful expulsion of tape-worm in ten cases, by the use of tannate of pelletterine.

CORRESPONDENCE.

Case of Renal Calculus.

EDS. MED. AND SURG. REPORTER:—

Mr. D. V. D., æt. 27, of bilious temperament, began to complain of dull aching pain in the lumbar region in June, 1883. Being hard worked mentally, and of a very sedentary habit, I attached little importance to his frequent, yea, almost constant complaints, till in October, when he was taken down with nephritic colic. This was relieved in the usual way with morphia hypodermically, etc. Contrary to the rule in a majority of these cases, the attack recurred again and again. Confirmed then in the opinion that I had an impacted, or, at least, a calculus in the kidney to deal with, I gave him all the usually prescribed remedies for the solution of the stone. But my hopes were blighted every time, till in January, 1884, I concluded to order lithiated hydrangea. (Lambert & Co.) I prescribed it in drachm doses four times a day. The patient, who, by the way, is a student of medicine and very intelligent, expressed himself in a few days as feeling better. He had only one attack of colic during the time he took the first bottle, and when he had used the second bottle he had a very light attack, in which he passed a skeleton-stone, *i. e.*, a mere shell. He is still using the medicine, but has had no return, and to all appearances is well. I have used the hydrangea in only one case of cystic disease outside that reported above, but with favorable results.

THOMAS M. JORDAN, M. D.

Hookertown, N. C.

Chronic Nasal Hemorrhage.

EDS. MED. AND SURGICAL REPORTER:

In the issue of April 5th of your valuable journal, I notice a correspondence by W. S. F., on a case of "Chronic Nasal Hemorrhage," in which the writer asks for advice.

It has been my fortune, or rather misfortune, to have seen a number of cases of chronic nose-bleed, and been called upon to treat them. The causes of this affection are so varied that I shall have to content myself with mentioning only a few of them which seem the most likely to be the origin of the bleeding in W. S. F.'s case.

Foreign bodies which children frequently push up into the nostrils cause ulceration of the mucous membrane when allowed to remain, and thus a small vessel is frequently opened, giving rise to hemorrhage more or less profuse. Nasal polypi, particularly of the fibrous variety, have a tendency to bleed spontaneously, and so have hypertrophies of the nasal mucous membrane. But a few weeks ago, I saw a case of chronic nose-bleed caused by a small aneurism situated in the mucous membrane covering the lower turbinated bone on the left side of the nose, which had been opened by ulceration. Another very frequent cause is a small ulceration at the lower portion of the cartilaginous septum, which is perhaps caused and kept up by the picking with the finger nail. Any one of these causes may be present in the case in question, but it is most likely that there is either a foreign body or polypus in the boy's nose, since the doctor states that the voice has a

nasal tone, indicating obstruction. It is not likely that there exists any hemorrhagic diathesis, since only one nostril bleeds, and no mention is made that the child bleeds excessively when the skin is broken in other parts of the body.

In regard to the treatment of these cases, the first step should be to cleanse the nostril from all clotted blood, and carefully examine the mucous membrane of the cavity for the bleeding spot, or for the cause, be it a foreign body, tumor, or hypertrophy. When found to be one of the latter, it should be removed by surgical means that will readily suggest themselves; but if it should be a simple ulceration on the septum, it should be touched with solid nitrate of silver, and the patient directed to keep his finger-nail away from it. There is no good in plugging the nostril with cotton soaked in astringent solutions, except when the hemorrhage is so copious as to be alarming, and then the plug should be taken out as soon as possible, and the cause removed.

There can be no evil effects following the cure of such cases, since the hemorrhage is not natural. On the other hand, the removal of the cause of the hemorrhage in the case of the boy, would rather tend to remove the anæmic condition and improve his general health, and particularly do away with the headaches which are due to pressure within the nasal cavities.

CARL SEILER, M. D.

Philadelphia, April 7.

NEWS AND MISCELLANY.

Kentucky State Sanitary Council.

(Concluded from page 477.)

"All crystallized sugars which have not been adulterated are comparatively harmless. Persons not taking much exercise, who take large quantities of sugar in the form of saccharose, will be able to dispose of no more than the amount of physical exercise and the demands of the vital forces require. To convert the saccharose into glucose is the natural course in the digestive process. Starchy foods, as is well known, must be converted into glucose in the normal process of digestion; but if they be so converted and then introduced into the digestive organs, indigestible ferments are produced and dyspeptic disturbances follow.

"Now, to return to the consideration of fruits. It must not be forgotten that all the ripe fruits, freshly taken, may be eaten in considerable quantities without detriment, and in most cases with advantage to the economy. Fresh ripe fruits assist the digestive organs in disposing of cured meats and of fatty matters; and whilst they contribute nothing of material value to the nutrition of the system, they are able to sustain life for a long time. When over-ripe, they cause fermentation in the alimentary canal, diarrhœa, and painful disturbances of the alimentary tract.

"Unripe fruits contain an indigestible and highly irritating substance, called 'pectose.' It has the marvelous power, when brought into contact with the gastric and pancreatic juices, of producing cells, identical in appearance and func-

tions with yeast-cells found in the liver and kidneys, and even excreted in the urine in diabetes mellitus. Eklund's observations, extending over a period of twenty years, published in the *Medical Herald*, August, 1883, tend to show that diabetes mellitus is the result of the growth of yeast-cells in the liver.

"What shall we say, then, of the dangers attending the use of cooked, unripe and over-ripe fruits? In a record of 9,012 cases of so-called naso-pharyngeal catarrh, 8,062 had well-marked lymphatic engorgement with enlarged tonsils, 8,654 confessed to the habit of eating cooked fruits, confections, and pastries daily. Out of 391 cases of tuberculosis, a persistent aversion to all kinds of animal foods existed in 254; of this latter number, not one recovered. Of 386 cases of persons emaciated and suffering chronic catarrh, change of diet and habits of life produced astonishing results—the longest period of time in any case of complete recovery being 8 months, the shortest 120 days. It is a little remarkable that the complete recoveries in the whole list were about equal in number to the consumptives who died. The most favorable subjects for treatment were those under thirty years of age. Animal diet in the form of fresh meats, milk, butter, and cheese, having been adopted to the exclusion of those articles believed to be noxious, allowing a liberal supply of vegetables and of ripe fruits uncooked, never failed to develop marked improvement independently of treatment. Tea should be prohibited, while the use of well-diluted alcoholic liquors, especially at dinner, is often necessary to stimulate the appetite for animal food, and to increase the capacity for digestion.

"Thus it would appear that domestic and personal hygiene should include the supervision of the diet, and that here lies the greatest field for the popular and general work of preventing disease.

THURSDAY.

Morning Session.

In the absence of Mr. Troutman, of Shepardsville, who was to have read a paper on "The Hygiene of Small Towns," Dr. Joseph McCormack, of Bowling Green, said:

"The dangers to which small towns are liable, arise in the main from the contamination of the soil and water by human excretions and kitchen slops, and the hygiene of towns without sanitary police inspection has reference mainly to the removal of these filthy products and a proper disposal of them. Systems of sewerage can not be advocated, because they can not be operated without a water system, and are too expensive. He recommended, therefore, the 'Pail System,' in successful operation in Lynn, Mass., and several smaller towns in Michigan and other parts of the United States. The system involves the idea of the construction of outhouses without vaults, the place of which is taken by large pails with a capacity sufficient to make their removal necessary once a week, and these to be removed by scavengers to convenient places for admixture into compost." This he stated had been done in many smaller towns at a cost of but \$2.60 per annum to each family, this including the expense of preparation for the operation of the system. The dis-

posal of kitchen-slops could be effected only partially by avoiding the practice of throwing them in one spot, and taking care to throw them in the winter where the garden will be made the following year, thus enriching the ground. The paper was freely discussed, especially with reference to what are called "the filth diseases," such as typhoid fever, yellow fever, and diphtheria.

Prof. J. W. Holland, of Louisville, read a paper on the subject of the contagiousness of consumption. He referred to an epidemic of acute consumption which occurred at a nunnery situated in Indiana, where one person having the disease and living in constant association with others, in the short space of nine months communicated the disease to nine other individuals, five of whom have died of the disease, two are rapidly sinking and will die soon, while the remaining two have the disease in a less virulent form and of a more chronic character. In these cases death will not result for perhaps several months, but these individuals will probably die of that disease in a comparatively short time.

The speaker then entered upon the consideration of the causation of the disease by the germ called "bacillus tuberculosis." There are a great variety of microscopic plants floating in the atmosphere we breathe, in the water we drink, in the food we eat, and which are constantly, therefore, being taken into the system, yet they do not all produce disease; on the contrary, many of them are salutary. In order to secure these bacteria of various kinds for microscopical inspection, it was discovered that by placing a boiled sliced potato exposed to the air there collected upon it a mold made up of these germs, which, having settled upon it, there found a suitable soil in which to grow and reproduce themselves. They present to the naked eye a variety of colors—red, green, and blue—when grouped together; and it was observed that one of these groups, being transferred to a fresh potato, always produced more and more, having the same color—red always produced red, and blue always blue. A peculiarity of one class of these germs was discovered to be a special affinity for the stain from aniline-coloring fluids. This class of germs, after having been transferred from one fertile medium to another, and allowed to grow through a series of fifty trials or more, was found to be the same.

These, after this series of trials, being injected into the blood of an animal, there found a suitable soil in which to grow, and multiplying themselves rapidly produced an infectious disease. The blood of this animal then being examined was found to contain these germs, and a drop of it being again placed upon sliced potatoes began again to produce germs identical with those produced before the series was broken, and thus they always remained the same. It was now discovered that one class only of these germs was capable of receiving a stain in a peculiar way. This class, after a series of reproductions, being injected into the blood of an animal, caused a disease identical in its manifestations and terminations with consumption. Then it was discovered that the sputa of consumptive persons always contains this particular bacillus, and that these can in like manner be cultivated upon gelatine indefinitely and always retaining the same characteristics, and,

after this cultivation, being injected into the blood of an animal produced consumption. This class was therefore named the bacillus tuberculosis. It is argued that if this bacillus is able to produce consumption in the lower animals, and if it is always found present in the sputa of consumptives and the tubercle itself, it is therefore the cause, and not a product of the disease. It is held that it produces its fearful work in the system by its power of rapid reproduction, one of these germs being capable of reproducing and multiplying to the amount of 40,000, or even 1,000,000, in a single day; that being foreign bodies, indeed bearing the same relation to the tissues of the organs in which they grow and reproduce themselves that the trichina spiralis of diseased pork does when it gains entrance into the system, they, by their rapid reproduction, insinuate themselves into the tissues of the lungs and other organs to such a degree and in such quantities as to produce constant irritation and inflammation.

Another factor necessary is the susceptibility of the person, which bears the same relation to this germ that fitness and fertility of soil bears to seed. That susceptibility is always great in proportion as the system is debilitated, whether that debility be a part of individual peculiarity which we at present recognize as hereditary, or whether it be acquired through exposures that lessen vitality, overwork, insufficient clothing, food, pure air, sunlight, or any other of the depressing causes that produce it by lowering the vitality of the system.

A few words may not prove uninteresting as to the peculiarity with which these germs called bacillus tuberculosis receive and retain aniline coloring dyes. As a matter of fact all these germs, whether harmless or virulent, will receive these stains; but so far as investigations have been pursued it is known that this germ both receives and gives up its stain much more slowly than the others with which it may be associated. Then when all together have remained in a coloring fluid sufficiently long to be stained, the quick action of an acid upon them decolorizes all but this particular class, which, as has been already said, receives and gives up its stain slowly. Then a short immersion in another colored fluid suffices to re-stain those just decolorized, without affecting the bacillus tuberculosis, which now under the microscope appears separate and distinct.

The practical bearing of this subject upon sanitation is this: If consumption be due to the combination of two factors, neither of which alone can operate to produce the disease, it would seem a rational conclusion that by preventing, if possible, these two causes from combining, the disease can be prevented. Might not then many cases of consumption be prevented by preventing persons who have inherited or acquired this condition of debility from association with persons known to have consumption, and in whose presence these bacilli are most likely to be rife?

In the afternoon, Prof. H. J. Greenwell, of Bardstown, read a paper on the subject of the importance of hygienic instructions by physicians in attendance upon the sick.

Prof. Wm. J. McConathy, of Louisville, then read a paper on "Hygiene in the Public Schools." This had reference particularly to the subject of

ventilation and heating of the buildings, but perhaps more particularly to some of the faults in the methods of teaching. As the reporter understands it, he thinks there are better and more nearly natural methods of teaching than by confinement of the attention of the child to so many text-books. The rules to some extent governing its physical welfare, he thinks, can be sufficiently impressed to guide the child often in its conduct, and conduce to its health and well-being.

Prof. J. A. Tanner, of Louisville, discussed and illustrated the subject of adulterations of food.

In the discussion of the proposed sanitary legislation in Kentucky, all seemed deeply interested, and many participated, Judge Wyckliffe expressing it as his opinion that the bill regulating the practice of pharmacy should be increased and made applicable to every portion of the State, without reference to the number of inhabitants of any particular section. He spoke at some length on the importance of the adoption of the bill regulating the practice of medicine.

At the close of the discussion, the convention, constituted of the citizens of Bardstown, Nelson county, and visitors, unanimously resolved that the bill to increase the efficiency of the State Board of Health, the bill to give effect and practical enforcement to the law intended to protect citizens of Kentucky against the dangers of empiricism and quackery in the practice of medicine, and an amendment to what is known as the State Pharmacy Laws, so as to make these apply to the protection of the whole people in every part of the State, should be enacted by the present Legislature; and it was resolved also that the foregoing should be presented to the Committee on Sanitary Regulations by the Permanent Secretary of the State Sanitary Council, Dr. J. N. McCormack.

Evening Session.

Dr. Dudley S. Reynolds, Chairman of the Nominating Committee, reported as follows: For President, Mr. George Baber, of Louisville; First Vice President, Dr. A. Crawford, of Bardstown; Second Vice-President, Prof. William J. McConathy, of Louisville; Third Vice-President, Prof. L. Eddy, of Danville; Fourth Vice-President, Dr. A. D. Rodman, of New Haven.

The report of the committee was, on motion, unanimously adopted.

Mr. George Baber, editor of the *Sunday Argus*, of Louisville, then read the following paper on "The Relations of the Press to Sanitary Reform:"

"The press is at once an obedient servant and a masterly power. It serves everywhere the common weal, and is the greatest foe of public wrong. Its influence embraces the scope of civilization. Its relations are as numerous as human wants. Wherever felt, it awakens thought and arouses action. It fosters progress and aids reform. It develops opinion, inspires effort, and directs each movement of the state. It is a patron of science, a champion of law, and the vital factor in every benevolent work. It seems befitting, therefore, on an occasion like this, that some words should be kindly uttered for the press. The work which engages this Sanitary Council involves the appliances of science, the authority of law, and the aims of popular beneficence. It is the problem of the State's supervision of the public health. This

problem, in its practical form, though comparatively new in Kentucky, has been surely coming to the front. It is superior, in fact, to every issue in politics, and above all cunning of the statesman's craft. It concerns every citizen's hearthstone and home. In 1868 the first step was made to organize sanitary work in the State, but its progress has been rapid and great. It is hailed already as a crowning merit. It has awakened the zeal of the medical profession. It has won the sympathy of the people. It has secured substantial though inadequate assistance from legislation. It has produced this enlightened body, and enlisted the support of the press. The latest experiments in the solution of this problem have magnified the value of sanitation, and justified the prophecy of the learned Henry Bowditch, who said, 'This business of governmental attention to public health is to be one of the great labors of the coming centuries in all civilized countries.' To this great labor the press must always bear an essential relationship. It can vitalize or it may destroy; it can build up, or tear down the cause. Its relation to the work in Kentucky should be that of encouragement to every faithful participant. It should uphold the State Board of Health, and co-operate with this Sanitary Council. The cultivation of a healthy public sentiment on this subject is as necessary as the use of disinfectants to purify the atmosphere. The best undertakings are often assailed by the malaria of prejudice—a poison that has frequently proved fatal to plans that would otherwise have become vigorous, thrifty, and blessing-full to mankind. Kentucky has too much of this poisonous air. It dwarfs personal endeavor. It deters public enterprise. It hurts the whole State. It keeps Kentucky lagging in the march of progress. In this condition of affairs, the press finds a great duty to perform, and its health-giving influence should be bravely applied to the task. The prejudice which ignorance has arrayed against sanitary reform must be driven away by its power. The work now done in the organization of sanitary boards in Kentucky is mainly the result of personal effort. In one hundred and nine of one hundred and seventeen counties, local boards have been formed under the auspices of the State Board of Health; but the aid from the State itself has been small. In some of these boards the element of usefulness, in others, the spirit of indifference prevails. In the best, as in all of them, there is need of encouragement and light. The advancement of the past decade has still left ample room for the development of popular sentiment and for awakening public thought on the subject. This task remains to the press. It constitutes, in fact, its principal relationship to sanitary work in Kentucky. In regard to this, as to every public work, the duty of criticism is important. The newspaper cannot ignore it. Criticism, however, should be thoughtful and timely, lest it be simply hurtful; nor should it exclude that noble sense of justice which appreciates honest effort, whether successful or not. The faithful physician who devotes to this reform both time and labor, cannot be infallible, and deserves generous treatment from the press. He is entitled to its aid. His faults need not be magnified, but his merits should be given that hearty recognition which dignifies the giver and fills the recipient

with strengthened joy. It may be said just here, that no vocation among men does so much unpaid toil of hand and of brain as the medical profession. Its good deeds are done wherever human suffering is seen. The ravages of flood and of storm, the relentless epidemic, the casualties of river and of rail, the wounds of battlefields, the sick of the hospital and the hut, alike command the service which is oftentimes given for neither charge nor pay. It is the good Samaritan among vocations. It is the poorest paid of the race. In fact, it is that profession 'whence comes the skill and wisdom to apply to the myriad uses of man the laws of nature; which tames the fiery spirit of the air, and transforms into faithful and unwearying servants the blind, unreasoning forces of the earth.'

"The press is the natural ally of such a profession. It is its brother in humanity's cause. It is the link that binds it to the welfare of the State. The press, therefore, must be employed to remove the obstructions to sanitary reform, honoring at once the workers and the work. Legislators and Governors feel its influence and are moved by its power.

"Thomas Carlyle, the famous author, perceived this fact when he quaintly said, 'Great governors, clad in purple and insignia, are governed by their valets, by the poutings of their women and children, or, in constitutional countries, by the paragraphs of their able editors.' And, in portraying the effect of organized popular thought when directed by the press in favor of great reforms, the same immortal writer said: 'Ever louder rises the plaint of such a multitude into a universal, continual peal of what they call public opinion. What king or convention can withstand it?' Public opinion is the formulated power of the press, and its potent influence is needed for the cause of sanitary reform in Kentucky. Historical evidences show that sanitary science and the printer's art are alike hoary with age. One thousand years have elapsed since the art of printing, antedating the crude contrivances of the German, Gutenberg, was discovered in Japan, where, in the eighth century, it was originated by a woman, the Empress Ghyantoka, and hid for centuries among the mysteries of the ancient kingdom. But sanitary science is older than the press. It is older even than Æsculapius, the founder of the healing art, whose gifted sons were the physicians of Homer. Though it be true that proper methods of ventilation are comparatively new in America, yet we are told that experiments at the pyramids in Egypt show that 'those Egyptian tombs were ventilated in the most perfect and scientific manner.' Near three centuries ago, sanitary appliances were well defined and conspicuously useful in Britain. To the sanitary police controlled by the Royal Society of England's capital, in restricting the plague of 1665, and in suppressing the conflagration that enveloped London in 1666, Macaulay has ascribed 'the changes which, though far short of what the public welfare required, yet made wide differences between the new and the old London, and probably put a final close to the ravages of the pestilence.'

"The importance of sanitary law has had an uncertain growth since the conception of medical science first dawned on the genius of Hippocrates

and Galen. Its pathway has been up and down, through the vicissitudes of a hard struggle for recognition. It has verified a memorable axiom of Rudolph von Irling, who pertinently said: 'All in the world has been obtained by strife; every principle of law which obtains had first to be wrung by force from those that denied it.' It would seem that Kentucky should be foremost in this struggle for sanitary reform. The State is rich in the annals of the medical profession. It has ever been a prominent seat of medical lore. Within its limits, at Lexington, was established the first medical school west of the Alleghanies. The State has given to the profession many bright names: McDowell and Dudley, Brashear and Briggs, Yandell and Gross, Mill and Bell, have illumined Kentucky's medical fame, and their example should inspire with zeal the courageous men who are giving now both time and labor to sanitary work. The work is vital to the State. Difficulties are in its way, but they are not insurmountable. They will yield before the progressive spirit that fills and impels the present generation of Kentucky. The croakers must stand aside. They should not have one inch room. The atmosphere of the State is uncongenial to the impractical vagaries of Herbert Spencer on the subject. Kentucky must be true to the fame of her great sons, and up with the strides of her sister States. A general Board of Health and a system of sanitary reform must be maintained liberally by the state. Perfection in the work cannot be reached at once. It is necessarily a gradual growth, and the mission of this Council is wisely and patiently looking to the end. The future conquests of medicine, despite the antiquity of science, are destined to exceed the achievements of the past. The profession looks forward to an ever-brightening future. Its discoveries can be limited only by the domain of human thought, and the day will come when fulfilling the prophecy of Sir James T. Simpson, the followers of Æsculapius 'shall be familiar with the chemistry of most diseases; when they shall look upon the cure of some maladies as simply a series of chemical problems and formulas; when medical men shall be able to stay the ravages of tubercle, blow out fevers and inflammations, avert and melt down morbid growths, cure cancers, destroy all morbid growths and ferments, annul the deadly influence of malaria, and by these and various other means, lengthen out the average duration of human life.'

"Kentucky presents a varied field for sanitary reform. The water-courses that bind the State's extensive borders; the recurrent floods that overflow our towns, devastate fields and imperil human life; the increasing number of our prisons and their inmates; the care of our asylums for the deaf, the blind, the feeble-minded, and the insane; the growing needs of our cities in reference to systems of sewerage and drains; the expanding populations that occupy districts which actually harbor contagion and malaria—each and all of these, in their relation to medical science, afford to the Kentucky student of sanitation exhaustless opportunities for investigation, study, and for work. The progressive press of the State is awaking more and more to these great facts. It perceives the broad field they offer to the devotees

of sanitary science. It hails with pride the deliberators of this Council. It is ready to assail with destructive force the obstacles that oppose it, and to you may be safely pledged to-day its generous aid in putting Kentucky foremost in the cause of sanitary reform."

An erudite and well-digested presentation of the importance of introducing the study of the rudimentary principles of sanitary science into all the public schools was made by Dr. J. N. McCormack, of Bowling Green.

Rev. Father O'Connell concluded the exercises in a humorous and entertaining criticism of the principal essayists who had contributed to the work of the Council.

On motion, the Council then adjourned, to meet on the first Tuesday of October next at Danville, Ky.

The American Medical Association.

The Chairman of the Section of Practice of Medicine submits the official programme for the meetings of the Section of Practice of Medicine, to be held in Washington, D. C., Tuesday, Wednesday, and Thursday afternoons, May 6, 7, and 8, 1884.

The following special subjects have been promised, and those who are announced to enter into the discussions have accepted, and will be present:

1. Discussion on "A Contribution to the Clinical Study of Epilepsy," will be opened by Professor William Pepper, of Pennsylvania. Dr. Roberts Bartholow, Pa.; Dr. Horatio Wood, Pa.; Dr. J. S. Jewell, Ill.; Dr. James T. Whittaker, Ohio; Dr. O. P. Hooper, Ark.; Dr. Eugene Grissom, N. C.; Dr. James E. Reeves, W. Va.; Dr. T. B. Lester, Kansas; Dr. Joseph P. Logan, Ga.; Dr. W. K. Bowling, Tenn.; Dr. John S. Moore, Mo.; Dr. James F. Hibbard, Ind.; Dr. J. J. Caldwell, Md.; Dr. John A. Murphy, Ohio; and Dr. A. P. Grinnell, Vt., are expected to take part.

2. A discussion on the "Clinical Study of the Heart Sounds," will be opened by Professor Austin Flint, Sr., of New York. Dr. Edward Janeway, N. Y.; Dr. William Pepper, Pa.; Dr. Frederick C. Shattuck, Mass.; Dr. John H. Bemiss, La.; Dr. James Wilson, Pa.; Dr. Richard McSherry, Md.; Dr. James R. Leaming, N. Y.; Dr. John S. Lynch, Md.; and Dr. A. B. Palmer, Mich., are expected to take part.

3. A discussion on "Tuberculosis" will be opened by Dr. Henry F. Formad, of Pennsylvania. Dr. Austin Flint, Sr., N. Y.; Dr. William Welch, N. Y.; Dr. N. S. Davis, Ill.; Dr. George M. Sternberg, U. S. A.; Dr. S. Fitz, Mass.; Dr. Henry O. Marcy, Mass.; Dr. James Tyson, Pa.; Dr. Edward Janeway, N. Y.; Dr. Charles Dennison, Col.; Dr. Henry F. Campbell, Ga.; Dr. W. T. Belfield, Ill.; Dr. Alonzo Garcelon, Me.; Dr. E. O. Shakespeare, Pa.; Dr. G. C. Smythe, Ind.; Dr. Harold C. Ernst, Mass.; Dr. W. E. Geddings, S. C.; Dr. Traill Green, Pa.; and Dr. John Lynch, Md., will take part.

The following papers are also promised:

Ayres, S. G., M. D., Theory and Instrument of Diagnosis.

Bartholow, Roberts, M. D., subject to be announced later.

Crawford, S. K., M. D., Etiology of Enteric Fever.

Duhring, Louis A., M. D., Dermatitis Herpetiformis.

Flint, Austin, Jr., M. D., Dietetic Treatment of Diabetes Mellitus.

Green, Traill, M. D., The New Official Chlorate.

Griswold, Gaspar, M. D., Irregular Apoplectic Attacks from Other Causes than Hemorrhage and Embolism.

Janeway, Edward, M. D., Simulation of Pathognomonic Signs and Symptoms.

Jackson, S. K., M. D., Typhoid Fever.

Keyt, A. T., M. D., Retardation of the Pulse in Mitral Insufficiency.

Linn, G. A., M. D., Specific Treatment of Diphtheria and Croup.

Marcy, Alexander, Jr., M. D., Muscular Hypertrophy of the Stomach.

Marcy, Henry O., M. D., The Germ Theory of Disease.

Miller, J. P., M. D., Phthisis, its Successful Treatment.

Prentiss, D. W., M. D., 1. Importance of Uniformity in the Pharmacopœia. 2. A Plea for Greater Interest in the Pharmacopœia on the Part of Physicians.

Reed, R. Harvey, M. D., Irritation of the Capsule of Glisson.

Schenck, W. L., M. D., Occult Causes of Disease.

Tyson, James, M. D., The Milk Treatment of Disease.

Welch, Wm. H., M. D., Pathology of Myocarditis.

Whittaker, James T., M. D., The Etiology of Pericarditis.

Wilson, James, M. D., The Diagnosis of Tumors of the Anterior Mediastinum.

Chemistry in China.

The Chinese have begun to adopt the Western chemical science, and a factory has recently been erected for the manufacture of sulphuric acid on a large scale. Two well-known chemical textbooks, Malgutti's "Elementary Chemistry," and Fresenius' "Chemical Analysis," have also been translated into Chinese with the help of a great number of new characters, and adopted into the Imperial colleges. His Excellency Tong Sung, First Minister, and a director of the Tung Wen Huan, has taken the work under his immediate patronage, and written a preface for the first of these books.

Burn Brae Private Asylum.

It gives us pleasure to testify to the admirable arrangements of this institution, its healthful location, and the excellent results it obtains. Few alienists in this country equal Dr. Given in long practical experience, and none surpass him in skill and kindness toward those committed to his charge. The location of the institution in the immediate vicinity of Philadelphia offers every convenience of access. We would recommend our readers who may be in search of a medical home for patients mentally affected, to address Dr. R. A. Given, Clifton Heights, Pennsylvania.

New York Neurological Society.

At the annual meeting of the New York Neurological Society, held April 1, 1884, the following officers were elected for the ensuing year: President, William J. Morton, M. D.; First Vice President, C. L. Dana, M. D.; Second Vice President, George W. Jacoby, M. D.; Recording Secretary, E. C. Wendt, M. D.; Corresponding Secretary, W. M. Leszynsky, M. D.; Treasurer, E. C. Harwood, M. D.; Councillors, E. C. Seguin, M. D., L. Weber, M. D., T. A. McBride, M. D., W. R. Bird-sall, M. D., Graeme M. Hammond, M. D.

Items.

—Where no special cause appears for frequent micturition, this trouble is best treated by passing a weak galvanic current from the lumbar region to the region of the bladder.

—Dr. Stogwart, of Brussels, has employed chrysophanic acid internally in sixty-one cases, comprising eczema, psoriasis, lichen, etc., and reports that fifty-six were complete cures.

—Dr. M. Pargamin reports the reduction of a scrotal hernia by fifteen minutes' faradization and manipulation, when three hours of taxis had signally failed. The tumor was faradized in all directions.

—The Russian government has conferred the grand cordon of the order of St. Stanislaus upon Prof. Frerichs, for the services rendered to Russian students by him in the universities of Breslau and Berlin.

—In the *Pacific Medical and Surgical Journal*, March, 1884, Dr. Julius Rosenstern reports a case of simultaneous ligature of the subclavian and common carotid arteries for aneurism of the innominata—recovery.

—The latest trick in professional advertising in New York city is to write, or have written, a biographical sketch of one's self for some obscure family paper, pay for an extra edition, and have specimen copies of the same distributed upon the thoroughfares.

—The *London Medical Times* calls attention to the excessive mortality from whooping-cough in that city for a number of weeks past, and advocates the establishment of half a dozen small hospitals for children affected with the disease, where they can "be rigidly kept in a temperature like that of a southern health resort."

—Three students of the Harvard Medical School, who recently passed their examinations, are not happy. One wrote an excellent set of papers, the other two copied them word for word, and the examiner ranked them at 98 per cent. He remarked, however, that as the three papers were identical this gave the three but about 33 per cent. each, and as 50 per cent. is required for a diploma, all three were plucked.

OBITUARY NOTICE.

ARTHUR M. WILSON, M. D., PH. D.

Dr. Arthur M. Wilson, son of Dr. Benjamin B. Wilson, died at his father's residence, 1903 Chest-

nut street, in this city, March 31st, in the 22d year of his age. Dr. Wilson was graduated from the University of Pennsylvania in 1882, taking the degree of Doctor of Philosophy in June of the same year. He immediately entered upon the active duties of his profession, establishing himself in the home in which he grew up to manhood. So favorably was he known and regarded, that his business became at the outset extensive as well as lucrative, placing him at once in a position that most young physicians are obliged to spend years to attain. But his health, never robust, and doubtless impaired by too continued and persistent study during the period of his pupilage, was now unequal to the demands upon it. The inevitable exposure and fatigues of a physician's life developed with him a constantly-recurring tendency to lung congestions, and he found himself unwillingly compelled to abandon his bright professional prospects, and seek a recovery in rest and the care of his family. For a time the efforts of devoted relatives gave hopes of at least a partial restoration; but the past winter has been especially a trying one to invalids, and he passed away peacefully and happily in the earliest bright days of spring.

Dr. Wilson's temperament was amiable and kind, yet dignified and self-asserting. He was enthusiastic in his profession, and of perception and judgment remarkable in one so young.

MARRIAGES.

DAVIS—BEDELL.—At Fortsville, March 13, 1884, by the Rev. E. N. Howe, Marco L. Davis, of Troy, N. Y., and Jennie E. Bedell, daughter of Rev. C. C. Bedell, M. D.

DUNHAM—DOWS.—At the residence of the bride's parents, Wednesday, April 2, 1884, by the Rev. William S. Rainsford, Carroll Dunham, M. D., and Margaret Worcester, daughter of David Dows, all of New York.

MAYGINNES—HALL.—At Mound Valley, Kansas, March 19, 1884, by the Rev. Hugh M'Birney, Niceus W. Mayginnnes, M. D., and Flora A. Hall, daughter of the late Rev. Wm. Hall, of the New York Conference.

ROGERS—SLEDGE.—In Como, Miss., March 20, 1884, Dr. S. A. Rogers, of Memphis, and Miss Pattie Sledge, of Como.

WOLFE—HASKELL.—In New Albany, Ind., March 27, 1884, Dr. H. S. Wolfe, of Corydon, and Miss Nealie Haskell, of New Albany.

DEATHS.

ARCHER.—In Pointe Coupee, La., March 17, 1884, of congestion of the brain, Dr. John G. Archer, aged sixty-four years.

CHIPLEY.—In St. Louis, March 16, 1884, Dr. William B. Chipley, in the eighty-fourth year of his age.

CORYELL.—In this city, April 4, 1884, Dr. R. H. Coryell, aged sixty-six years.

KENNEDY.—In New York city, Saturday, March 29, 1884, James Kennedy, M. D., aged eighty-four years.

NEALL.—In this city, March 29, 1884, after a lingering illness, Dr. Samuel W. Neall, aged seventy-six years.

RISING.—At Sufield, N. Y., March 27, 1884, Aretas Rising, M. D., aged eighty-two years, three months, and twelve days.

SMITH.—In Greenville, Ind., March 24, 1884, of paralysis, Dr. Reuben C. Smith, a resident of Floyd county over sixty years, aged eighty-one years.

WILSON.—In this city, March 31, 1884, Dr. Arthur M. Wilson, youngest son of Dr. Benjamin B. and Mara L. Wilson, aged twenty-one years.

WHITE.—In Macon, Ga., Sunday, March 30, 1884, Dr. J. A. White, of Brooklyn.

1. A CASE OF SCORBUTUS. 2. A CASE OF SUPPOSED GRAVES' DISEASE.

A CLINICAL LECTURE DELIVERED AT THE PHILADELPHIA
HOSPITAL.

BY EDWARD T. BRUEN, M. D.,

Demonstrator of Clinical Medicine University of Pennsylvania and one of the Physicians to the Philadelphia Hospital.

GENTLEMEN: The patient before us is a Hungarian, and has a very imperfect understanding of the English language, so that we have been unable to acquaint ourselves very thoroughly with his history. So far as can be made out, it appears that he has been working on the railroad at Phoenixville, and for from ten days to three weeks before admission to the hospital had been suffering from some form of disease attended with fever and extreme debility. He was admitted on the 19th of the month, one week ago. That evening the temperature was 103°, the pulse, 100. On the morning of the 20th, temperature, 102°; pulse, 104. Evening, temperature, 103.8°; pulse, 104. On the morning of the 21st, temperature, 102°; evening, 103°. On the 22d the temperature suddenly fell to 98°. The other symptoms which were noted on admission, were an exceedingly feeble action of the heart, the first sound being so feebly developed that it seemed as though the slightest movement would occasion syncope; there was also marked congestion of the lung as indicated by bronchial breathing and impaired resonance on percussion. The physical signs taken in connection with the history, the high tempera-

ture, and feeble pulse, led the resident physician to suspect when he first saw the man that he might be suffering from pneumonia. The examination made the following day disproved this idea: in the first place, because the physical signs were bilateral, and as you can readily understand, extensive bilateral pneumonia is inconsistent with life; and in the second place, because the above physical signs had to a great extent disappeared, showing that the consolidation was more apparent than real, and due simply to congestion of the lung.

The appearance of the case suggested that the man might be suffering from typhoid fever. The temperature on admission certainly favored that view, there being a continued fever, with a slight remission between the morning and evening temperature. The history was quite negative, but there were certain considerations about the case which seemed to shake the plausibility of the diagnosis of typhoid fever. The most conspicuous of these considerations was the extreme weakness of the heart, and yet the phenomena of the typhoid state, which are usually associated with such profound cardiac weakness in typhoid fever, were not present, for, you know, that when the extremely weak pulse appears in typhoid fever, it is, as a rule, associated with a peculiar nervous exhaustion. Again, the appearance of the patient's tongue did not favor the idea of typhoid fever, for it was neither brown nor dry. There was, also, an entire absence of abdominal symptoms. By abdominal symptoms, I do not mean diarrhoea alone, or tenderness alone, for, as you perhaps know, typhoid fever often runs its entire course without either diarrhoea or abdominal ten-

derness, and there may even be constipation. In typhoid fever, however, there will usually be found a certain amount of tympanitic distension of the abdomen. This is a very constant symptom. This patient's abdomen is concave. Moreover, there is absence of eruption and no enlargement of the spleen. These points must be associated with the fact that the patient had evidently been ill for at least two weeks, so that he would have passed into the stage when these common and ordinary symptoms of typhoid fever appear.

The next most plausible idea that occurred to us was that the man was suffering from some form of malarial fever. While in the hospital, he had fever without intermissions and even without marked remissions, and the idea of malarial fever was therefore rather negatived at the outset, and yet it is important to analyze the *tout ensemble* of the case. In doing so, we must recall the fact that his sickness has lasted two or three weeks, and has apparently constantly presented the same aspect as it did a few days ago. The occurrence of remittent fever indicates a high degree of malarial poisoning, and this marked malarial impression is characterized by congestions of the internal organs, as the spleen, liver, and digestive circulation. We find no enlargement of the spleen, no evidence of congestion of the liver as shown by constipation, enlargement of the organ, or symptoms of intestinal indigestion. Taking these things in connection with the fact that the temperature was not intermittent and not even remittent, and the fact that there was no history of chills, we laid aside the idea of malarial poisoning, but kept it in abeyance to a certain extent, because malarial poisoning is an exceedingly insidious complaint, and very irregular. I do not think that in any clinical diagnosis we should ever settle down upon a conviction unless all the evidence fits together as do the separate figures of a puzzle. I am sure that the longer you study diseases the more satisfactory your work will be if you so endeavor to combine them.

Is there any other disease from which this patient could suffer which would be more in accord with the history and the symptoms? There is one disease, not a very common one, and yet perhaps its minor manifestations are less often recognized because less often looked for. I allude to a dyscrasia of the blood tissue brought about by imperfect nutrition and improper hygienic surroundings. You recollect that this patient has been working in the cold and damp weather of the past few months, and as a foreigner, unable to

speaking the English language, he has probably been more exposed to hardships than a person familiar with the language would have been, and I fancy that his diet has been limited and insufficient. With these preliminary suggestions, let me ask, what was the most prominent symptom which this patient presented on admission? At the outset of my remarks, I mentioned that the first symptom which attracted our attention was great feebleness of the heart. This was so conspicuous as to lead us at each visit to the patient to increase the amount of stimulus until he received ten ounces of whisky and two ounces of alcohol per day. I only mention this to show you how convinced we were of the importance of this symptom. Although he received such a large amount of stimulants, the weakness of the heart continued, and it persisted despite the additional use of digitalis. When his mouth was examined, it was found that the gums were spongy, swollen, and bluish in appearance. A part of the bluish discoloration was, however, due to the accumulation of tartar on the gums. The face presented a dusky hue, somewhat analogous to sun-burn, which covers up a yellowish discoloration. In spite of the redness which was due to local congestion, there was anæmia of the mucous membranes, and a dull and sodden appearance about the face. On examining the body, there were found a few stripes running across the abdomen, which resembled the stripes left by a whip. These are technically called vibices. There was also a dusky line around the waist, indicating the point at which pressure had been made by the strap which held the pantaloons in position. Other than these, there were no ecchymoses, spots, or other eruptions on the surface of the body.

With these facts at hand, I think that we have a more plausible explanation of the symptoms in the dyscrasia of the blood than in the theory of either typhoid or malarial fever. Scorbutus or scurvy is very rare as a well-marked affection. Last year, however, I had the opportunity of studying a well-marked case of scurvy in the University Hospital. This had developed in the Italian quarter of the city, in an Italian who had been without sufficient food, or at least without a sufficient variety.

The three marked symptoms of scorbutus are, spongy gums, infiltration of the muscles, especially those of the calf and of the tissues around the joints of the lower extremities, with petechial eruptions and extreme weakness, especially of the heart. These are the most characteristic, although there are many other symptoms connected

with the anæmic condition of the blood ; for in scorbutus the lesion is supposed to be in the blood-tissue. This lesion is presumably a deficiency of the positive alkaline salts, and a preponderance of the neutral salts—consequently, the blood becomes more highly acid than it should be ; the alkalinity of the blood being lessened, leads to an imperfect elaboration of the red blood corpuscular elements, and a condition of anæmia ensues. This anæmia, I say, results from the imperfect elaboration of the red corpuscular elements, and is due to the action of the acids in the blood on the corpuscles ; yet in certain advanced and severe cases of scorbutus, in addition to imperfect formation there is a destructive action exerted by the acid condition of the blood upon those corpuscles which may be formed in the blood-vessels. This condition is a progressive one. It has its period of invasion and its period of full development. It never appears in a moment, and therefore it is easy to understand that if you examine a patient in the early stages of imperfect elaboration of the blood, the disease may be diagnosed without all this array of symptoms. Of the characteristic symptoms previously mentioned, there are but two found in this patient, the spongy gums and the extreme cardiac weakness. These two symptoms are perhaps more constantly present in scurvy than any others. The reddish hue of the face is not inconsistent with the idea which I have mentioned, for in the early stages of scorbutus the red corpuscular elements are not especially affected.

I have already alluded to the condition of the muscles of the lower extremities. The muscular tissues generally are infiltrated with an albuminoid material, which exudes from the blood-vessels and fills up the interstices of the muscles, so that when a section is made they cut like a specimen which has been imbedded in wax. There is a law, gentlemen and ladies, which governs the processes of disease, which, I think, is well illustrated in this case. The law is that lesions appear in the points of the body which are most exposed to overstrain. There is a close analogy running through the processes of disease which can be applied in this way. In rickets the lesions in the bones develop in those bones which are most used, that is, in the bones of the forearm, for the child crawls before it walks. The lesions also appear in the ribs, because these are in constant action. So in heart affections, the changes in the muscle correspond with the amount of strain upon the muscle. The same is true in scurvy. The lesions of the gums occur chiefly because the teeth

are used in chewing. Where the teeth have been lost, the lesions of the gums are very apt to be absent. This has been a well-sustained and constant observation. The muscles of the limbs, being more constantly used than the other muscles, are the favorite seat of the lesions. The eruptions on the body are apt to be connected with irritation of the clothing, and here we have noticed the brown discoloration across the abdomen where the brace of the pantaloons has pressed.

With these facts, I think that if we can only account for the high temperature, the diagnosis will be pretty well established. I would call attention to the fact that, as a rule, scorbutus is not a febrile disease. For instance, it is improper to speak of scorbutic fever, but it is proper to speak of the fever of scorbutus. What is the fever apt to be due to? In nearly all cases, to some complication. Sometimes this is found in the condition of the muscles of the legs, for this exudation of plasma into the muscles is frequently attended with some inflammatory disturbance in the joints or elsewhere. In the present instance the high temperature was probably connected with the pulmonary complication, which, in its turn, was dependent upon the cardiac weakness.

Looking at the case in this way, we can understand why the digitalis and whisky were inadequate to produce a stimulant effect upon the heart. The heart muscle was so degenerated that it could not respond to the stimulants any more than a weak and exhausted horse could respond to the stimulation of the whip. The primary condition for the use of stimulants is that the heart should be capable of stimulation. In this case, it seemed as though the heart were not so.

Looking at the case as one in which a scorbutic tendency had developed gradually and very insidiously, we should expect that the results of treatment would confirm this view of the case. After the man had been in the hospital two or three days, a large dose of quinine was given with the idea of controlling the temperature. Only one dose was given, and it was after this that the temperature fell ; but your experience will not parallel a case of remittent malarial fever in which the process was arrested by twenty grains of quinine. I am inclined to consider the rise in temperature as a temporary incident in his sickness—that the quinine simply reduced the temperature for the time being, and that in the meantime the cause passed away and there was, therefore, no return of the fever. It is hardly probable that if the man had had this high temperature while at

Phoenixville, any physician would have sent him to Philadelphia.

What are we to do for our patient? On admission, the first indication which presented itself was to overcome the weakness of the heart. At that time the man certainly could not have moved about with prudence, for syncope sometimes occurs in these cases from suddenly getting out of bed, just as it does in typhoid fever. No drugs are necessary, change of diet being the most important element in the treatment. This change must be one that introduces into the system the alkaline salts which the system seems to need; in other words, the potash salts. Yet not the potash salts alone, for a meat diet is not sufficient. Patients will develop scurvy on an exclusive meat diet. A vegetable diet must be combined with the meat diet.* Lemon juice is one of the most accessible remedies. Next to this we have mashed potatoes, cabbage, and other fresh vegetables. Fresh meat is also to be employed. It is probable that the potash salts are not the only ones of which the blood is deprived. I refer to this again because some writers have advanced the idea that because, in scurvy, there is a deficiency of the potash salts in the urine, the administration of these salts is capable of curing the disease. If it were impossible to procure lemon juice or fresh vegetables, the matter might be compromised by administering the potash salts with the mineral acids.

When scurvy is diagnosed in its early stages, it rapidly responds to treatment. In many cases, a few weeks is sufficient to remove the evidences of the disease. This patient has been placed on the treatment described. In addition, we shall simply use such remedies as are calculated to improve the nutrition of the cardiac muscle. I allude to arsenic and iron.

Although there are some other interesting features about this case, I pause at this point in order to bring before you another patient, who presents a curious combination of symptoms.

You will at once notice that there is a marked disturbance of the innervation of the vascular system, and also that the manner of the patient is very excitable and nervous. The eyes are slightly staring and protruding, although this is not sufficient to prevent closure of the eyelids. At the same time, the conjunctiva is white and glistening, and the eye bright. The extremely excited action of the heart can be seen even at a

distance. When the hand is placed on the abdomen, a strong pulsation is felt. The carotids also beat violently. The thyroid body is distinctly enlarged, and on placing the hand over it a thrill is detected.

There are here three symptoms which are often associated with a disease which is known by the name of an Irish surgeon, as Graves' disease, or by the name of an English observer, as Basedow's disease; and it is also named from two of the symptoms, the protrusion of the eyes, and the enlargement of the thyroid, as exophthalmic goitre.

I desire rather to call your attention to the clinical peculiarities of this particular case, than to give a didactic lecture on exophthalmic goitre. I would merely say that the pathology of this disease is still very imperfectly understood; but the essential element of the affection is supposed to reside in the sympathetic nervous system, especially in the cervical sympathetic, and that the characteristic symptoms—that is to say, the throbbing of the blood vessels of the neck, the excited action of the heart and the protrusion of the eyeballs—are due to vaso-motor paresis, by which the vessels become dilated, and so imperfectly enervated that this throbbing of the arterial system occurs. In advanced cases there is another factor in the protrusion of the eyeballs, found in the changes which take place in the eye itself. At times, the eyes protrude so much that the lids cannot be closed, and there is a want of co-ordination between the muscles of the eye and those of the lid.

It is evident in looking at this man that there are present, to a certain degree at least, the symptoms of exophthalmic goitre. There are pulsation of the arteries, protrusion of the eyes, some enlargement of the thyroid, and extreme nervousness. I think that in a disease which has such an obscure etiology as exophthalmic goitre, we may well recall the proverb that "every swallow does not make a summer." These symptoms of incipient Graves' disease may not be expressive of that particular disease which is characterized by these symptoms in the well-marked stage.

Let us examine the history of this patient, for he has been in the hospital for several months. He was admitted for an injury to the leg. At that time, he was free from any of the symptoms which he now presents. These have developed in the house. The first symptom complained of was palpitation. When a patient comes with palpitation of the heart, you will first review the causes of functional palpitation, such as the use of tobacco or alcohol, excessive sexual indulgence,

*NOTE.—Dr. Dickenson reports a case of genuine scurvy in a girl ten years of age whose diet had for some months consisted chiefly of bread and butter, with no meat and little or no milk.

business anxieties, extreme bodily exercise, with an imperfect vascular organization, and the like. This patient does not appear to have been exposed to any of these causes of palpitation. The disease appears to have commenced with an inability to assimilate food, and for a long time he has complained of vomiting. This has not been associated with any signs of organic or inflammatory affection of the gastro-intestinal tract. The tongue is not red and raw, but has rather a natural appearance. There is no tenderness in the abdomen, although there is some pain. This pain is, I think, connected with the throbbing of the aorta. This vessel is beating constantly against the spinal column, causing a pain something like aneurism; yet it differs from aneurismal pain, in the fact that it is not especially relieved by change of position. Neither are there any of the physical signs of aneurism, as tumor and murmur. None of the conditions which predispose to aneurism are present, as syphilis, rheumatism, and alcoholism. We may therefore consider this a functional derangement of the stomach.

It remains to be seen whether we shall call this patient's condition an idiopathic derangement of the sympathetic nervous system, in which there is increased action of the accelerator nerves and paresis of the vaso-motor nerves, or whether another explanation of the case should be attempted. I should only go farther because I think it probable that something may be accomplished in the way of treatment on a different theory. So far nothing has been accomplished during the past seven months.

It seems possible to me that this condition of the sympathetic nervous system has developed in consequence of some defect in the diet which the man has received since he has been a resident of the house. The first thing is to act upon the stomach with something which will cause the food to be retained. Since it has been recognized that the vomiting is of nervous origin and not dependent on organic disease, I should first advise the use of hot water. A cup of water as hot as can be swallowed should be taken in the morning, and directly afterwards the food which has been decided upon. The most digestible food for a patient in this condition seems to me to be scraped raw meat. This is, of course, open to the objection of the possible introduction of the tape-worm, but scraped meat with vinegar is by no means an unpalatable dish. If the patient can not take this, the meat may be slightly broiled, then chopped fine and made into little cakes. If milk could be taken, this might be used. It may be

made more digestible by associating it with some of the preparations of the American Health Food Company, which I have so often recommended to you. We might start with hot water, gluten food and milk; a little later in the day, hot water and scraped beef; still later, another portion of milk and gluten food, preceded by hot water.

Failing in this, the different series of remedies to control this irritability of the stomach may be used. These include the preparations of creasote, cerium, and many others, which I shall not take time to enumerate. One is, perhaps, as good as another, and it may, at some stage of the case, be necessary to use each one. The best of these for this patient would probably be the nitrate or oxide of silver. I should first give the nitrate in combination with belladonna, and if this did not answer, substitute the oxide for the nitrate.

I shall also order for this case, after the irritability of the stomach is controlled, the use of cider-vinegar, lemon juice, and such an antiscorbutic diet as he can take, feeling that there must be something wrong with the previous treatment. With this it would be advisable to act on the sympathetic nervous system in the neck and abdomen with electricity. The patient will be placed on the treatment indicated, and when the stomachic symptoms are less prominent, we shall direct our attention more particularly to the anæmia. It would be improper to attempt to act upon this now, for the condition of the digestion would hardly tolerate the use of iron. I make this remark because salts of iron are often given in conditions of this kind. There is a time to withhold iron, as well as a time to give it.

At a subsequent clinic, I shall report the progress of this case.

COMMUNICATIONS.

INEBRIETY FROM BAD SURROUNDINGS.

BY T. D. CROTHERS, M. D.,

Superintendent Walnut Lodge, Hartford, Conn.

Lord Shaftesbury, in a speech before the House of Lords on the "Lodging House Bill," remarked that his attention had been repeatedly turned to the fact "that bad and unsanitary surroundings was a very active cause of inebriety, not only among the poor and defective classes of large cities, but among the better and more favored circles of society."

It is apparent to any one that tenement houses and their surroundings, wanting in ventilation, cleanliness, and sunlight, would of necessity les-

sen the vigor and health of its inmates, and be followed by various neurasthenic conditions for which alcohol would bring most seductive relief. The residents of such places, in most instances, are not only poisoned by the many bad conditions of living, but are under-fed, from food wanting in quality, quantity, and preparation. They are also in most cases of the defective class, with entailments of past generations of disease; and altogether inebriety seems to be a most natural outgrowth of all these conditions, giving momentary relief, and almost euthanasia, from the increasing misery and sufferings. The inebriate lifted out of these bad conditions of living, and given good food in healthy rooms, would, of course, recover more readily from his malady. All efforts in this direction to save the inebriate, and prevent inebriety, that do not begin on the physical side, with a change of surroundings, and all unsanitary states and conditions, will fail. The reformer and physician must recognize and act upon the fact that both health and disease are very largely the result of surroundings and conditions of living.

While these facts are understood and fully recognized among the occupants of tenement houses in cities, and the poor generally, they are frequently unobserved in the wealthy and better classes.

Elegant houses, luxurious furniture, and rich food, may be as thoroughly unsanitary and injurious to health as the lowest tenement in the worst locality.

Ventilation, sunlight, cleanliness, bad food, may be as marked here by their absence as elsewhere. In a consultation at the home of a wealthy inebriate, I found the victim sleeping in a room with heavy velvet curtains at the windows and about the bed; a dark closet and bath room, in which a gaslight burned all the time, opened into the room; a dry furnace heat from the basement poured into the room, and the only ventilation was into the hall equally warm. The air was charged with bay rum used in bathing, and his food was highly spiced and richly seasoned, taken any time when from whim or notion he desired it. After an evening at the theatre or club room, ending in a rich dinner with wines at midnight, he retired to this badly-ventilated room, and spent seven or eight hours in feverish, troubled sleep. A late breakfast, with various spirits, roused him up so he could go down to his office. Two hours here, then more spirits and food, a short ride, the club house and places of amusement, spirits and food, and back again to a home wretched in its

luxury. To recover in these surroundings was impossible. First of all, he needed a total change in conditions, where pure air, sunlight, and food could aid in restoration, then the removal of alcohol, and building up of the weakened brain and nerve system would be accomplished.

My purpose is to indicate that bad physical surroundings, in many cases, is a predisposing and exciting cause of inebriety among the active and better classes of society. A clinical record of some cases, which have fallen under my observation, will bring out these facts more clearly. I will divide these cases into two groups, one in which a marked neurotic tendency existed from heredity, and the other in which this was absent, or so obscure as to escape observation. The following are cases of the first group:

A., father a moderate drinker, several uncles inebriates, and mother a nervous, melancholy woman. He began life as a clerk, and by hard labor and great industry became wealthy, and at the head of the firm at forty. He was temperate and regular in all his habits, and in good health. He moved into a fashionable house, with luxurious appointments, and three years after, began to drink at night for its narcotic effect. He did not go into society, or have any intimate association with drinking men, but drank to relieve a feeling of restlessness and obscure pain. He went on swiftly from bad to worse, drinking to intoxication every night, but attending to business during the day. His disposition changed and he became more grasping in business, and less inclined to see any one. He came under my care suffering from delusions of persecution, and extremely weak, drinking all the time to intoxication if he could get spirits. All spirits were removed, and the recovery was very marked and rapid. Two months later, he resumed business; and six months after I was called to see him at his house, having relapsed and developed a mania of poisoning, supposing his wife and servants were trying to kill him in this way. He occupied a dark bed-room, heavily furnished with bed curtains, and draperies at the doors. An unventilated closet and room into which furnace heat poured without any outlet, with various other unsanitary conditions, showed clearly the cause of his inebriety.

From my advice, he moved into the country, and lived in better surroundings, and has abstained and become a temperate man since then.

It was apparent that his inebriety grew out of the unventilated surroundings, and a low state of health, producing sleeplessness and debility, for which alcohol was found to be a remedy.

Case B. was a wealthy merchant from an interior village, who moved to a fine mansion in New York, and after a few months became an inebriate, and two years later went back and reformed, and is now a temperate, sober man. He inherited a positive neurotic diathesis, but having been educated for a physician, and given great attention to building up his body, he became a vigorous, strong man. From his own statement, he became depressed, and could not sleep well at night in the city. Dyspepsia, severe neuralgias, and various functional derangements followed. He used wine and beer at first for this state, with relief; then later, stronger alcohols, until the craving for spirits was beyond all control. He found that in the country this craving was greatly reduced and could be controlled, but in the city he was powerless to resist it. He lived in the best surroundings a city could afford, but in his estimation the bad air and want of sunlight were the active causes of a lowered state of health which merged into inebriety. The change in the time of taking food was also a factor of importance. The final recovery in the former home, where all these conditions were different and more perfect, was evidence of the correctness of his views.

Case C. was still more striking as an example of this class. A manufacturer who had drunk to excess in early life, reformed and was an exemplary temperance man in the widest sense. He had two sons associated with him in business. Both of them were temperate and vigorous, and having a personal prejudice against all use of spirits, were total abstainers from principle and practice. One of them went to New York to take charge of the sales-room of the manufactory. He lived in a rich boarding-house, worked hard, did not go into society or have drinking associates. Two years after, he began to use alcohol to excess, beginning as a medicine at first, then the demand for it was imperative and irresistible at night. He was a secret drinker in his room for a long time. Then he drank in his office, and finally was intoxicated about the store. He went back home, and his brother took his place. He was under my care for three months, and recovered, and is now temperate and well, at work with his father in the manufactory.

His brother in New York boarded at the same place, and was equally hard-working, and retiring from company, and yet within a year he became an inebriate. He would drink in his room and office for two days, then reform and be sober a week, and begin again. After two years he came back home and reformed, and is now liv-

ing as before, only a very radical temperance man.

From the general evidence of the surroundings in New York, it was apparent that they were the active factors in the cause of the inebriety. The boarding-house was wanting in many essentials of healthy living, and his office was dark and badly ventilated. He dined at a saloon in the middle of the day, and ate a hearty dinner at night at the boarding place. The general strain and exhaustion of work was not relieved by food or rest, because the means to this end could not be obtained in the surroundings.

The second class or group are precisely like the first, except there is no history of heredity or previous neurosis that would predispose to this condition.

The following is a marked case: D., a lawyer, of health, and a total abstainer. No heredity was apparent, and he was extremely careful of all his work and habits of life, yet he became an inebriate after two years' residence in a flat in New York. He suffered greatly from malaria, and went up to the Catskills, where he fully recovered from both inebriety and malaria. A year later he returned to the city, and soon began to drink again. Losing all his property forced him back to his native town on the Connecticut river, where he is now living, a temperate, healthy man.

I have noted a number of similar cases, which differ only in some circumstances and incident, with the same chain of causes, producing the same results.

These causes come in general from every bad state of living, beginning with unventilated sleeping and living rooms, which are so apparent among the low tenements of the poor in large cities, and are masked and covered up in the homes of the wealthy by rich furniture, pictures, and draperies.

Extending to the nutrition and food of the very poor and very wealthy, both wanting in healthy preparation and quality to properly nourish the body. The extremes of exercise and activity meet and become active factors, and inebriety comes from it as naturally and positively as the oak comes from the acorn. The bad conditions of living in tenement houses are breeding-grounds for disease that can be seen; but equally fertile soils are found in the mansions of the wealthy, where diseases grow luxuriantly, but largely unobserved.

Inebriety, so common in the children of the very wealthy, no matter what the moral influence has been, is often traceable to low vitality and

nerve force, the direct result of unsanitary surroundings.

Of course, many other causes enter into the ætiology of each case, but this is a factor that should receive attention, and is within the power of the person to remedy and prevent.

All residents of large cities will recognize the number of healthy, temperate men in middle life, who come into the cities with property, and after a time become inebriates, lose their money, and disappear, or leave a family who contribute to the very worst elements of society.

There can be no doubt that in many cases bad surroundings contributed largely to this end—surroundings of luxury and fashion, that are wanting in the most important elements of health. If the person comes with a neurosal diathesis, he suffers more positively, and all these complex forces act as exciting causes to bring out the latent nerve defects.

Business men who are under a great strain during the day, and go home exhausted at night, must have surroundings which will bring perfect quiet and rest to both body and mind. If they do not, inebriety and a long train of maladies are invited in, and soon run into chronic forms and conditions. In these cases the first effect of bad air, and food taken at unseasonable hours, and defective in quality, is dyspepsia, and other nameless digestive troubles; bitters containing alcohol are first used with relief, then wines and strong spirits soon follow. If opium in any form is used at first, the same results, in the continuous use of the drug are seen in most cases. The inebriate who becomes alarmed at his condition, will turn to opium as a lesser evil, and from this he will go down readily. The opium case in like manner turns to alcohol to get rid of the opium mania. Probably ladies in the higher circles of society, who live in these bad unsanitary surroundings, are more often the victims of alcohol, opium, chloral, and the other narcotics, than men who are out in other conditions of living many hours of the day. The conditions favoring this are all present, and the results can not be otherwise.

A neurotic but temperate family moved from a country village to a fine residence in New York. In five years the mother was a moderate and excessive drinker at times, and two daughters used opium. The physician who reported this fact, wrote me: "I have no doubt in my mind that this was both the direct and indirect result of the surroundings and a neurotic diathesis which might have been prevented in more favorable sanitary conditions."

How far this condition of bad surroundings causes inebriety can not be accurately determined, but there are many reasons for believing that a large proportion of the alcohol and opium cases among the wealthy come from this source.

Bad company, idleness, and general fashionable dissipation, are, of course, factors of more or less prominence; but the conditions and influences of surroundings, poisoning the blood, and continually undermining the vital energies of the body, are causes largely unrecognized.

The treatment of these cases depends on the removal of all unsanitary conditions of living; and this means, in most cases, removal to the country, in large, sunny houses, where the ventilation and quiet will encourage and aid restoration.

A neurotic family are in great danger in the average wealthy mansion of the city. The reformed and restored inebriate will often find more danger in the richest city homes than in the common tenement.

The active brain-worker who neglects the sanitary condition of his home, has no prospect of long life or freedom from inebriety. Just as the child who is brought up in the low tenement, with every healthy condition of life wanting, is crippled, and all his future usefulness impaired, so the sanitary imperfections of a rich city home, and bad diet, will permanently mar and distort the future vigor of its inmates.

When the world shall comprehend that inebriety depends very much on physical conditions and surroundings, then the means for its successful treatment and prevention will be applied, and we shall be able to cope with this giant evil of the age.

HOSPITAL REPORTS.

Sayre's Extensile Splint for DISEASE OF THE ANKLE JOINT.

CLINICAL LECTURE DELIVERED AT THE BELLEVUE HOSPITAL MEDICAL COLLEGE,

BY LEWIS A. SAYRE, M. D.,
Professor of Orthopedic Surgery.

Reported by EDWARD DEVELIN, M. D.

GENTLEMEN: To day I call your attention to disease of the ankle joint. I will first make a few remarks in relation to its anatomy; this is a purely ginglymoid joint, in which there is no lateral movement. The joint is composed of three bones, namely, the tibia, fibula, and astragalus; these are held in contact by the external, internal, and posterior ligaments, the joint being lined by its synovial membrane; underneath this membrane we have the articular cartilage of the joint, which contains neither blood vessels or nerves,

but receives its nutrition by imbibition; beneath this cartilage lies the cancellous bone-tissue, which is freely supplied with blood-vessels. The tendons which pass over the joint have each a separate bursa; these may become inflamed at times, resulting, perhaps, from some injury, which may lead you to suppose the joint itself is diseased. Synovitis of this joint may occur through cold and exposure, but more frequently it is the result of a wrench or strain being followed by an acute effusion into the joint. You may also have an osteitis from the effects of a blow or concussion, which will bring about an effusion of blood into the cancellous tissue of the bone, which may be the cause of serious disease; in the course of time necrosis and caries following.

Some authors term this, chronic disease of the joint, progressive disease of the joint.

The reason why this disease is so slow in its progress, apparently assuming a chronic form, is simply because the injury which caused it was at the time very slight. A moderate amount of pressure being brought against the side of the joint may result in the extravasation of a single drop of blood into the cancellous bone-tissue; now this injury is so slight that the man may continue at his work, but this slight injury, in perhaps from six to twelve months, has then produced such marked injury as to demand attention.

In our examination, we then find increase of temperature in the part, perhaps accompanied with a semi-fluctuating feeling and intense pain upon pressure in certain positions.

The diagnosis of osteitis is not always easy; there is usually pain, and if you apply the surface thermometer, you can detect an increase of temperature; on examining the joint, by using compression and extension, you will be able to detect the disease in either ligaments or cartilage. If you stretch the ligaments, it will cause pain if the disease be in the ligaments; if the disease be in the bone, pressure upon the parts will produce intense pain. I do not believe that the disease commences in the cartilage itself, but being devoid of sensibility, it undergoes change and becomes necrotic after the bone has become diseased; the cartilage becoming absorbed, leaves the cancellous bone-tissue exposed, then the pain becomes excruciating. When the cartilage becomes ulcerated, there is a thickened condition of the synovial membrane ensuing, and its secretion becomes gelatinous and of a reddish color. If the disease be not arrested, caries of the bone takes place, and as soon as the slightest portion of the bone becomes dead it becomes a foreign body, and is the source of constant irritation until it is removed; the slow process of nature may, in time, burrow through the tissues, and thus the bone be discharged. The greatest difficulties that I have seen occurring in the ankle-joint, arise from very slight injuries.

A case that came under my treatment was that of a farmer who simply twisted his foot while plowing, and at the end of two or three years he had a diseased joint, which it was thought would require amputation. He was sent to me as a specimen of chronic disease of the joint, which is claimed to be the result of a strumous affection; but this is not so in the great majority of cases, and even in those persons of a strumous diathe-

sis it will require some injury at a special point in order to form a primary lesion. In this case a large amount of bone was removed, and following this was an extensive hemorrhage; the wound was at once filled with oakum saturated with persulphate of iron; the man finally recovered with a good, useful foot, having a perfectly movable joint.

I saw a young lady two days ago who had had her ankle locked up for two years in a plaster of Paris dressing, without affording her any relief; but on the contrary, the disease was still progressing. There had been no extension made at the time the dressing was applied; the diseased surfaces had been locked up immovably, but they were still pressing upon each other, and hence absorption of the structures was still going on. She came to me, and I at once applied the extension splint

(Fig. 1), which gave her immediate relief. I removed the splint the next day, and at once the pain was as severe as before, showing that the articular surfaces being brought together caused this intense pain.

The extension splint which I use for the ankle joint you will notice consists of an iron foot-plate with an anterior and posterior rod, each composed of two pieces, sliding into each other by means of a ratchet and key. These rods extending upward to just below the knee are attached to a collar, which passes around the leg. The posterior rod, just at the heel, has a joint at that point, while the anterior one is attached to the central portion of an arch passing over the foot. Just anterior to the arch the foot-plate is divided and hinged in order to allow of flexion of the toes—the foot-plate at the heel being slightly narrower than the heel itself in order that the foot may not slide from side to side. This point must be specially attended to when ordering the instrument.

In applying this instrument, I first pass inch-wide strips of the mole-skin adhesive plaster parallel with the leg from just above the ankle to the knee, placing them almost close together all around the leg, and securing them firmly by a roller-bandage. Then placing a piece of old linen under the foot upon the foot-plate of the instrument, to absorb moisture, I secure the foot in position with adhesive plaster to the instrument, as I

here show you. (Fig. 2.) I now pass a roller bandage around the foot, over the plasters, and secure them firmly, leaving, as you observe, the ankle-joint exposed. Then securing the collar of the instrument just below the knee, I reverse the ends of the adhesive plaster over the collar, and then pass another strip of plaster around the collar over the other strips to hold them in place, supplementing the same with a roller bandage, which I pass down the leg also. You hat the instrument is firmly se-

cured, and I am prepared to make my extension, which I do by first keying out one rod and then the other, until I have reached the correct point, which affords most relief. This being done, I am now at liberty to make my compression around the joint as may be indicated, covering in the whole with a roller bandage. As the dressing is now complete, the parts are entirely covered in (Fig. 3). But always make your extension at that stage of the dressing, as I just now showed you; do not make your extension after your dressing is complete and the parts are all covered, or strangulation may occur and necessitate the instant removal of your dressing.

If the a
by a sudde
ing out of
height, pu
hot water,
several ho

ing the heat of the water borne. On removing the apply a snug bandage, and keep it on for a few days. In the morning find that this treatment when applied early.

There are also a great many by massage for a number of days to increase the circulation and cause extravasation; this, however, is an experimental treatment which will not answer in all cases. You may sometimes secure absorption of the fluid in a few days by this method; it is at all events worthy of a trial. There is no law by which you can be governed as to the treatment by this means; you are safer, therefore, to rely upon giving the joint complete rest for a little while, until the inflammatory action has subsided. In some cases it may be necessary to apply leeches or cups to lessen the amount of blood in the part; but I prefer to use the cups and prick the parts with a sharp tenotomy; by this means you avoid the bad leech-bites. Persons who have a bad diathesis do not bear leech-bites well, as it may be followed by an erysipelatous inflammation. Many of these cases of ankle-joint disease are reduced to a bad condition by the long-continued use of poultices. These solicit more blood to the part, and the foot becomes one boggy, doughy mass. Apply firm compression around the joint, and you will be surprised at the result. When the connective tissue becomes loaded with this exudation, the more it is pressed the worse it will become. When the inflammation has gone on to suppuration, do not open it, but let it out the pus; avoid the use of vessels and tendons; always use the roller bandage. If you find the foot dead, take it out, as it is then a question of time until it is removed there is no cure. Keep the limb in the horizontal position as long as the ankle throbs when you get up. Do not let them assume the position too early. You can never have a cure of the joint without a reflex action of the muscles following sooner or later. This cannot be arrested. This, of course, leads to deformity, the stronger muscles

hence the more common deformity is talipes equinus, with sometimes more or less valgus or varus. To prevent that, you should always make extension. It is absolutely necessary to secure extension as well as rest for the part, the extension being applied with sufficient force to prevent compression of the articular surfaces—the contraction of the muscles then becomes nil. Very often there is an enormous amount of effusion around the joint, which can only be relieved by firm compression. In this case, use a large wet sponge, squeezing out all the water, then bind it firmly around the joint, after which dip the joint in water or pour water over it, and the sponge absorbing the moisture will secure still greater compression. Many persons used to amputate these joints. I, however, think cases of diseased joints but seldom require amputation. Here (showing cast) is a case in which I was called upon to assist at an amputation of the ankle-joint. I came to the conclusion, after examining it, that an effort should be made to save the foot, as it appeared to be tolerably healthy. My suggestion was adopted. Extension was then made, and the foot secured in the manner described, with the most satisfactory results. The plaster-of-Paris bandage is not the best splint to be used in this disease. The diseased joint must be treated on the principle of preventing muscular contractions, with such dressing as can be easily readjusted at any time. The result in this case was a perfect and complete recovery.

Here is another case which had been condemned to amputation. Seven years ago the boy sprained his ankle; five years later I opened the joint freely, and inserted setons, also making extension upon the foot. The patient is now perfectly healthy, the treatment having resulted in the saving of the foot, with good motion.

Here also is a young girl who just a year ago was brought here with diseased ankle-joint. The same treatment was followed out, and you now observe a complete cure has been effected.

This boy now before you has been presented at a previous clinic, and you observe that with the extension splint applied, he can bear quite firm pressure upward; but there is still pain upon pressure being made laterally, as you observe. He will, however, continue under this treatment until all inflammatory action and pain has disappeared, and I have not the slightest doubt a perfect cure will be the result in his case also.

Case 3. This little child was brought to me some three months ago, suffering from disease of the ankle-joint. At that time it was characterized by that peculiar boggy feeling which I have before described in these joint diseases. In this case the extension splint has been used, and in addition the sponge has also been applied around the joint to secure additional compression. The splint has now been worn for about two months. The mother states that the child has had no pain at all, and when the instrument is properly adjusted, she can play around the house with the other children. Now you observe here that by pressure upon the child's foot I cause no pain. To-day we will omit the use of the sponge, and now, having extended the joint, I make firm compression around it by means of the adhesive plaster and the roller bandage. You thus have

the joint entirely at your control when dressed in this manner. You notice that the child cries most lustily during the dressing of the foot, but it does not cry from pain, for you see that the moment the mother takes the child it becomes perfectly quiet, and yet the foot is in just the same position; it is a cry of anger, not pain. I see no reason why this child should require any further treatment than is now given, as it is progressing most favorably.

In those cases where an abscess appears and you find excessive inflammation, you can freely open the joint and let out the pus. In diagnosing for pus, hold one finger absolutely still and gently pass the other over the inflamed surface, in a line parallel with the long axis of the muscles; do not go from side to side of your finger which is stationary, or you will be deceived by the lateral movement you cause the muscular tissue to make; but go above and below with the long axis of the muscular fibre. By this means of slight compression you will cause the pus to pass under your other finger, and thus distinctly feel the fluctuation; this is a simple, practical point. In these cases the abscesses must be thoroughly evacuated either by aspiration or free incision; if the latter, it should be freely washed out antiseptically, and filled with Peruvian balsam, and dressed with oakum; then allow your patient to get out as soon as possible. Now, if you thoroughly master the principles of this treatment, you can perform these operations equally as well as myself, and thus save the joint from amputation.

Case 4. In this boy's case the extension splint has been removed from the ankle, and in its place has been substituted a piece of sole leather which has been thoroughly wetted, and then moulded to the foot and ankle while it was extended; it was then bound securely to the joint with a roller bandage, and allowed to remain there until it had become thoroughly hardened, when it, of course, assumed the exact moulding of the parts; you then cover this leather splint on both sides with mole-skin adhesive plaster, the adhesive side out, and apply it once more to the limb, at the same time making traction upon the foot and securing the splint to the foot with a roller bandage; this being accomplished, extension is now made, and your bandage continued above the ankle up the leg; the splint is thus firmly secured, and extension of the joint maintained sufficient to prevent attrition of its surfaces.

Often, in many of these cases where you are unable to secure the leather or extension splint, you can fold a piece of paper up very tightly, then cover it with a piece of adhesive plaster from end to end, on both sides, with the adhesive side out. Then bend it to fit the anterior portion of the foot, allowing it to pass up the leg. Now fold up another piece of paper, and cover in like manner, and apply to the sole of the foot and pass up over the heel. Having placed these in position, I take a roller bandage and secure them firmly to the foot as far as the ankle. My assistant then making traction upon the foot, I continue my roller bandage above the ankle-joint and up the leg over the paper splint, the adhesive plaster holding it in position, and by this means my extension is maintained.)

< In this case before you I shall again apply my

extension splint, in order to make the adjustment more perfect. I merely show you the method of adjusting this leather or paper in such cases where you have not the opportunity of securing the iron splint. This latter, however, can always be procured from my instrument-makers, Messrs. Reynolds & Co., 309 Fourth Avenue, of this city.

Med Surg Reporter.

NEW YORK HOSPITAL.

CLINIC OF PROF. WILLIAM H. DRAPER.

Reported by W. H. SEELYE, A. M., M. D.

Iodism.

The first patient I show you, gentlemen, is the man whom you saw last Monday (page 488), who had had syphilitic ulcers on the ankles, which had been successfully treated by the mixed treatment. But while the ulcers were improving, he had developed an eczematous eruption, chiefly upon the extremities. This I supposed to be due to the iodide of potassium which he had been taking. So the drug was discontinued, and I think the result justifies the explanation which was given. For, as you see, the swelling and redness have subsided, and the eczematous surface is healing rapidly, and in a few days he will probably be entirely well. He is taking no medicine now except the citrate of potash, given to promote the elimination of the irritating poison by the kidneys. An ointment has also been used locally to lessen the irritation of the skin which attended the inflammation of its follicles.

MEDICAL SOCIETIES.

PHILADELPHIA CLINICAL SOCIETY.

Stated meeting, March 28, 1884, the President, Dr. Henry Beates, jr., in the chair.

Dr. Daniel Longaker reported a case of

Sudden Death in Diphtheria.

The patient, Mary F., æt. 6 years, was seen first on the afternoon of the second day of the disease. Her temperature was 104°⁰, and the general symptoms were of a decidedly adynamic type. She complained of pain and difficulty in deglutition, and a nasal tone of the voice was noticed. On inspection of the throat congestion and swelling were evident, and a small patch of false membrane was found on the right tonsil. The local trouble continued to grow worse until the fourth day, and was associated with a diminished secretion of urine, in which albumen was found to be present. The membrane was detached on the sixth day, and by the tenth convalescence was established. On the thirteenth day she was seen for the last time. Her pulse was a little accelerated in frequency, and still weak. Her appetite was good, and she was sitting up and going down stairs. Two days later, the fifteenth of the disease, after rising in the morning and feeling quite well, she suddenly fell from the chair from which she was attempting to rise, and expired.

Dr. Joseph S. Gibb read a paper on

Umbilical Hemorrhage.

In the preliminary remarks he spoke of the neglect of medical writers in omitting this important topic from their works, in spite of the oft-repeated mention of this negligence by individual observers, who, while investigating, have sought in vain in most of the standard works of the day for some account of this accident. Notable exceptions to this are the works of Simpson, Condie, and more particularly Dr. Bedford, of New York. The author spoke of the rarity of the accident, and proved the same by reference to the records of maternity hospitals and foundling asylums, and also by the experience of the older members of the profession, and finally presented a collection of 241 cases, which represented those which have been published since 1752.

The author's case was a female child of a "bleeder" mother. Hemorrhage began on third day from birth. No single bleeding-point was observed. The hemorrhage was simply a continuous oozing from the bottom of umbilical depression. Several ligatures were applied directly to the cord, and then the ligature en masse, all of which failed to control hemorrhage. This was finally accomplished by a solution of the sub-sulphate of iron painted over umbilicus, and a pledget of cotton saturated with same solution bound fast over umbilicus. The child suffered considerably from the profuse bleeding, though soon rallied after its cessation. Was strong and healthy when last seen, one month from date of accident. There were no premonitory or accompanying symptoms. It was simply a spontaneous umbilical hemorrhage.

The author makes three divisions of the subject:

1. Hemorrhage from improper ligation of cord.
2. Hemorrhage, the result of traumatism.
3. Spontaneous hemorrhage.

The first two received but cursory attention, the cause and remedy being apparent. The third variety formed the true basis of the paper. He did not believe that any of the so-called premonitory symptoms, viz., colicky pains, jaundice, etc., can be relied on as such, but thought they may occur in otherwise healthy infants, or precede other affections. However, he laid stress on the fact of a hemorrhagic diathesis existing in either parent, and believed this should make us watchful. He regarded the subjects of umbilical hemorrhage as those suffering from a general disease, and hemorrhage the first symptom of this disease. This symptom may occur at any time from a few hours to eight weeks after birth. The next most important symptom is jaundice. Both of these symptoms occur in an equal number of cases.

As regards the etiology, the author believed there is a direct relationship between the hemorrhage and some constitutional condition of infant, which condition may be either hereditary or congenital. The hemorrhagic diathesis was given a first place in the list of causes. It is not considered absolutely necessary to invoke the aid of the hemorrhagic diathesis in the parent to establish the existence of this condition in the offspring; in other words, it may be congenital. Attention was drawn to the hemorrhagic symptoms in these cases, viz., hemorrhage from bowels, gums, and penis, as proof of this peculiar condition being a strong etiological factor.

Jaundice was mentioned as forming the favorite ground of most writers on the subject as a causation of umbilical hemorrhage, but the theories on which this is based were not regarded as substantiated by post-mortem examinations. In but few of the recorded cases were there any indications of a syphilitic or scrofulous taint. Various other minor causative influences were noted, viz., excessive use of alkalis by pregnant women, insufficient food, etc.

In conclusion, it was admitted that in the present crude state of our knowledge of umbilical hemorrhage, we are obliged to admit several etiological factors.

In an analysis of the reported cases, there is found to be a strong predisposition on the part of the male to the occurrence of this accident. In 115 cases collected where the sex is mentioned, 67 per cent. were males.

The morbid anatomy of the subject is very incomplete, being made up of statistics as to the potency or non-potency of the fetal openings and vessels, the condition of the liver, and the character of the blood—from all of which no satisfactory conclusion can be drawn. The prognosis of umbilical hemorrhage was stated as excessively grave—a mortality of 83 per cent. in 230 cases. The fatal termination may occur at any period, from one hour to eight weeks from commencement of bleeding. In 94 cases, where the time of death has been stated, 47 or 50 per cent. occurred within first 48 hours—twenty-five in the first, and twenty-two in the second twenty-four hours.

The success of therapeutical measures the author believes lies in a proper appreciation of the nature and causes of the disease; and until this is accurately determined, umbilical hemorrhage will continue to resist all well-meant therapeutical resources.

In the present state of our knowledge, the author believed that that treatment will be the most successful which consists of local styptics, ligature, etc., combined with such internal hemostatics and tonics as experience has proven of value in kindred hemorrhagic affections of adults.

Dr. Albert H. Smith, in opening the discussion, said:

"I have seen two cases of the kind referred to by the reader of the paper. The first occurred at the end of 24 hours after birth, in a healthy child. On attention being called to it, the ligature was found loose; this was reapplied carefully. On the following morning the nurse again discovered hemorrhage, and the child died before I could reach the house. This was not a case of neglect or traumatism. The other instance occurred also in a perfectly healthy child 48 hours old. The cord was ligated by myself, but I soon found hemorrhage occurring freely from the tissue around cord; a large compress of absorbent cotton was applied by means of Seabury & Johnson's plaster, and a teaspoonful of magnesia given internally. The child was saved. In these two cases there were no hereditary tendencies to this form of trouble; no jaundice; no purpura hemorrhagica in either the mothers or the infants themselves. We have not so far reached any reasonable theory of its etiology. Jaundice seems a coincidence. Great stress has been laid on hæmophilia, but my experience does not bear it

out. In a family under my care four out of five died of hemorrhage, but none showed any tendency to umbilical hemorrhage. In the autopsies of fatal cases no uniform non-persistent conditions have been found. My cases are somewhat remarkable from the fact that recoveries are rare.

"In the treatment we could hardly expect a compress to do much, yet I think this application the best that can be made. A laxative would contribute to lessen blood pressure and act as a revulsive.

"I would suggest that hemorrhage from non-application of a ligature would rarely occur in health, if we are to judge by the fact that in Germany they seldom tie the cord. Difficulty may certainly arise from too early ligation. My practice is not to ligate until the cut extremity has ceased bleeding."

Dr. Charles K. Mills. "I have had one very interesting case of umbilical hemorrhage which recovered. The subject was the fourth child of perfectly healthy parents, the other three children being healthy. There was no trouble until the third day after birth, when an oozing was found at umbilicus, and the child vomited blood; the cord was examined and found not bleeding at the extremity; subsequently styptics were applied, without result; the hematemeses occurred on three occasions during the following twenty-four hours of occasional hemorrhage. The bleeding was finally controlled by transfixion with needles, and a half drop of amm. sulph. acid administered every two hours. The child recovered, and is now perfectly healthy."

Dr. Hannah T. Croasdale. "I have had the opportunity of seeing but two cases of umbilical hemorrhage. The first was from shrinkage of the cord and great amount of gelatinous material. After the ligature was closely reapplied, the bleeding began again from the cut extremity. I then applied Peau's hæmostatic forceps, and left them in position twenty hours. In the other case the hemorrhage was controlled by tightening the ligature."

Dr. Mary Willits. "To the cases mentioned, I would add one seen by myself in hospital. The child was a week or ten days old. After considerable hemorrhage, the bleeding was successfully checked by styptics and a compress."

Dr. Henry Beates, jr. "In connection with the hematemeses noticed by Dr. Mills, a case seen by myself showed at the autopsy gangrene of the ilium. There was also sloughing at the extremity of the cord."

Dr. Joseph S. Gibb. "I am grateful to the members for the relation of their experience with this troublesome affection. The relation of the hemorrhagic diathesis to it is yet a question. There seem, however, to be two things intimately connected with it—the hemorrhagic diathesis, and jaundice. The case reported by Dr. Mills would rather support the former theory. It is evident that loosening the ligature would be a dangerous experiment in some of these cases."

Dr. Collins exhibited a bullet that had been removed from the anterior nares of a man. It had remained embedded in the turbinated bones since 1865. An opening in nasal septum remains, produced at time of reception of wound.

NEW YORK NEUROLOGICAL SOCIETY.

Stated meeting, March 4, 1884, W. J. Morton, President, in the chair.

First paper:

Dr. C. L. Dana read a paper upon "Morbid Somnolence,"* relating a number of histories illustrating different forms of this affection. These forms are classified as follows:

1. Epileptoid sleeping-states.
2. Hysteroid sleeping-states, including (a) spontaneous or "mesmeric" sleep, (b) trance and lethargic states.
3. Morbid somnolence, the expression of a distinct neurosis. (Narcolepsy.)
4. Unclassified forms.

The speaker's first case (illustrating class 3) was that of a young man of wealthy family and personal history, who would go to bed at the ordinary hour and could not be roused till noon, or afternoon, or evening of the next day. This would continue for a week or two, when the symptoms would remit.

A second case (illustrating class 2) was that of a young lady who had short attacks of catalepsy, cataleptic *petit-mal*, alternating with sudden attacks of sleep. These came on several times daily. Three other cases (illustrating class 3) were of neurasthenic persons who for several months had persistent drowsiness, not attributable to any nutritive or organic disorder.

Dr. Dana also reported a case furnished by Dr. L. Putzel, illustrating the epileptoid sleeping states.

Discussion on Dr. Dana's Paper.

Dr. Wm. M. Leszynsky: "I know of two cases which might be termed a mild form of morbid somnolence, where the patient would fall asleep at almost any hour of the day, while reading or conversing, the sleep lasting at times for an hour or more. The cause of this somnolence seemed to me to be undoubtedly due to faulty assimilation of food, and was cured by the use of nitro-muriatic acid, etc."

Dr. Weber: "I have seen but a few cases. In diabetes, morbid somnolence is believed to be a prominent symptom. I have seen twenty or thirty of such cases, well pronounced, but have not seen one case where morbid somnolence prevailed; on the contrary, the patients did not sleep as much as normal. I remember two cases of locomotor ataxia, in which there was a great tendency to prolonged sleep; in one of these cases, the man would sleep often fifteen hours at a time.

"I have observed sopor in chronic endarteritis, in a number of cases, especially in cases where the condition of cerebral arteries tends to apoplexy. There was one man who would fall asleep during dinner, be taken up to bed, and there sleep till the next day."

Drs. Roberts and C. E. Nelson made remarks, giving cases, as to making up sleep-time after prolonged vigil; Dr. Roberts remarked that sopor was met with in his case of myxœdema, read previously before this society, and published in this journal; in such cases, sopor is recognized as a symptom of disease.

*This paper will appear in full in the April number of the Journal of Nervous and Mental Diseases.

Dr. Shaw (of Brooklyn) related a case of a man who would fall asleep in the clinic.

Dr. R. B. Prescott said: "I have one case bearing on this subject, Mr. President, which came into mind while Dr. Dana was reading his paper, and which, as it may not be altogether without interest, I will relate. It is that of a farmer, unmarried, forty years of age or more, living in a small village in Massachusetts, who, some ten years ago, began, without any apparent cause, to be troubled with excessive drowsiness. It manifested itself first in a disposition to sleep unseasonably long in the morning. He would remain in bed until long after the breakfast hour, and complain at intervals during the day of still feeling sleepy. Gradually he came to neglect the work of his farm, and remained about the house dozing away a considerable portion of the time. His social nature too underwent a decided change. He became reserved and silent. He shunned all intercourse with friends and acquaintances, was with difficulty made to answer ordinary questions, and was easily moved to tears. On one occasion I was told that he fell asleep on his wagon while taking a load of produce to the nearest market town, and slept soundly for many hours, his horse having of his own will taken an unfrequented road, and finally stopped at the place where he was discovered, the driver still fast asleep.

"His condition at present is that of a gradually deepening mental lethargy. He passes a large portion of his time in bed, and takes little interest in what takes place around him, though at times he partially arouses and will read the newspapers or carry on a brief conversation, mainly in monosyllabic replies to questions. His bodily functions are all normal, and there is no evidence of any physical disease. His general health was good up to the time of the appearance of this morbid somnolency, and he is not the subject of any hereditary taint so far as known. He is now regarded by those who know him as mildly insane, and his recovery is not expected."

The President said: "I have seen and treated but one of these very peculiar cases, which I should be willing, following Dr. Dana's lines of diagnosis, to classify as true morbid somnolence. Of course, those who sleep after prolonged forced wakefulness do not fall within the author's categories.

"As an instance of simple sleep of this nature I well remember of sleeping twenty-four hours without a moment of recollected consciousness after two days and two nights in the saddle during a time of great danger. This may be said to be simply normal somnolence. The case of morbid somnolence I refer to was that of a physician in this city, who had suffered from this condition for fifteen years. He was habitually overcome by an uncontrollable desire to sleep during the day time, no matter how *mal apropos* the time or place; this desire he would fight against with all his power of control, but would finally yield to sopor. Even in the dentist's chair, while a sensitive tooth was being 'scraped,' he had fallen asleep. Often in the rounds of daily practice he would feel this lethargy creeping over him at critical moments, as for instance when his services were most needed at a confinement, and

would be forced to yield to it and sleep. It was impossible for the same reason for him to read or study—in fact, life was becoming to him a soporific blank.

"Other symptoms were forgetfulness, frontal and occipital headache, a general malaise, great sense of weariness, palpitation of the heart on active exercise, and prostatic irritation. He had been examined time and time again by friends of eminence in the medical profession for organic disease, and none existed. The urine especially had been the subject of careful tests. I repeated these examinations, with no better results. Malaria was out of the question. I treated this patient on the basis of a profound anemia—gave him large and increasing doses of iron (Bland's pills) until he was taking thirty grains three times daily—gave him additionally, glonoin. Under this treatment he improved wonderfully, and at his last visit several months ago he reported that he seldom fell asleep during the day."

Dr. Dana, in closing the discussion, gave a similar case to the English farmer; this case would have periods of remission for several years. These cases are supposed to end in insanity. There is persistent drowsiness in diabetes, and in syphilis; also, previous to attacks of epilepsy. There is recognized a "sleeping sickness" in Africa; the French authority, Ballet, mentions these conditions.

Second paper—"Treatment of Wry Neck by Sulphate of Atropia." By W. M. Leszynsky, M. D.

The reader related the history in the case of a young woman whose occupation being that of a bookfolder, she was obliged to turn her head very frequently toward the left side. The right sternocleidomastoid and trapezius muscles became affected with a very severe form of clonic spasm which almost exhausted the strength of the patient. The treatment adopted was the daily injection of sulphate of atropia into the contracting muscles, beginning with gr. 1-80 and gradually increasing to gr. 1-6, which maximum dose was continued four days, when recovery supervened.

In addition to the atropia, galvanism was used, and the faradic current was applied to the opposite side.

(To be continued.)

Easy Writing.

The London *Lancet* very sensibly says: "Brain tension is not a proof of strength, but of weakness. The knit brow, straining eyes, and fixed attention of the scholar are not tokens of power, but of effort. The intellectual man with a strong mind does his brain-work easily. Tension is friction, and the moment the toil of a growing brain becomes laborious, it should cease. We are unfortunately so accustomed to see brain-work done with an effort, that we have come to associate effort with work, and to regard tension as something tolerable, if not natural. As a matter of fact, no man should ever knit his brow as he thinks, or in any way evince effort as he works. The best brain-work is done easily, with calm spirit and equable temper, and in jaunty mood. All else is the toil of a weak or ill-developed brain straining to accomplish a task which is relatively too great for it."

PERISCOPE.

The Radical Cure of Hernia.

We take the following from the *Med. Times and Gaz.*, December 29, 1883:

The radical cure of hernia has, until within the last few years, been a comparatively rare operation. Five years ago Wood's operation was occasionally performed, and Wutzer's operation only served to test the knowledge of the student. In the Liverpool Medical Society, on December 20, a discussion which arose on a paper on this subject by Mr. G. G. Hamilton elicited the fact that within the last three or four years about a hundred and fifty radical cures have been performed by the surgeons of that city. Mr. Banks has performed between fifty and sixty, Dr. Alexander about thirty, Mr. Rushton Parker twenty-eight, the Surgeons of the Northern Hospital fourteen, whilst Messrs. Pughe, Rawdon, and others, have operated on smaller numbers. The mortality has been *nil*, and the successes highly satisfactory to all, as far as time has enabled them to judge. The operation consists in tying the neck of the sac, and severing the neck thus tied from the rest of the sac. Mr. Rushton Parker stops here, and has had a success quite satisfactory to himself. Dr. Alexander adopted that method for a time, but he now joins all the other surgeons in dissecting out the severed sac, because it makes the cicatrix firmer, and gives a better support to the ligatured neck. In inguinal hernia especially, and to a certain extent in every variety, all the surgeons who spoke, with the exception of Mr. Parker, bring together by suture the fascial boundaries of the opening, which in inguinal hernia are formed by the pillars of the ring. Mr. Parker would only do this in exceptional cases. As to the material to be used for tying the neck of the sac and suturing the pillars of the ring, there was wide diversity of practice. In the Northern Hospital cases which were performed by Mr. Manifold, Mr. Puzey, Dr. Macfie Campbell, and Mr. Damar Harrison, chromic catgut was generally used for both purposes. Mr. Banks ties the neck of the sac with chromic gut, and brings the pillars of the ring together with silver-wire sutures, which are to be retained indefinitely. If the sutures irritate, all the better, as they can then be removed. If they do not irritate, it is still well, as they will always maintain their hold. Dr. Alexander uses catgut for the neck of the sac, and silver-wire sutures for the pillars of the ring. He removes these sutures before the wound closes, and looks with favor on healing by granulation. Mr. G. G. Hamilton recommended fishing gut or sulphurous gut for both purposes; and Mr. Rhinallt Pughe spoke highly of the latter as being pliable and making a firm knot. It was therefore evident that good results could be obtained by any of these methods, and that the kind of suture was not essential. This method of radical cure is capable of being performed in all kinds of hernia, reducible or irreducible. In all cases, the sac having been dissected out from its surroundings, and especially

from the cord in male inguinal hernia, is opened, and, if irreducible, the contents explored, the adhesions severed, and omentum removed if necessary. Mr. Banks and Dr. Alexander have successfully removed great masses of adherent omentum in this manner. In reducible hernia the sac is always opened, to see that the hernia is *completely* reduced. This free opening of the sac is not, therefore, new in Liverpool, although Mr. Lawson Tait, in the last number of the *Birmingham Medical Review*, puts it forward as a new practice in that town. Mr. Banks described in great detail the cases suitable for operation. It need not be performed in young children except under exceptional circumstances, as a truss generally cures such cases before puberty was reached. The exceptional circumstances were a very wide opening, or the presence of the disease debaring an orphan from a charity school, or inability or dislike to wearing a truss. In adults it should only be performed in omental hernia and in hernia complicated with undescended testis, on account of the exceptional danger of such cases. In ordinary cases of reducible hernia he would not operate unless life was rendered miserable by the disease, or the patient was thereby unfitted for work. When a well-fitting truss completely relieved the patient, he would not recommend an operation. As to the after-treatment, all agreed upon the advantages of a prolonged rest in bed for at least three weeks. Some of Mr. Parker's cases were up in ten days, and others in fourteen days, and he now believes that these periods were too short. In most of the cases no appliance was used afterwards. Mr. Banks, however, recommends a light truss to be always worn after operation. He does not believe in a *radical cure* of hernia in the sense of the patient being as strong in the region operated on as a perfectly healthy man would be. The wearing of the truss is no discredit to the benefits of the operation, and is an additional security to the patient. The results at the Northern Hospital were, up to the present time, ten cures and two failures. In two cases the interval was under six months, and therefore the question of cure could not be entertained; they had not failed. The dressing varied as much as the kinds of ligature and suture. Mr. Rushton Parker first introduced the operation into Liverpool, and thought the idea was new to others, as it was original with himself. He afterwards found that it had been performed by Dr. Macleod, of Calcutta, by Drs. Annandale and Buchanan, and by some others. In the successful and frequent application of the operation, it will be seen that Liverpool occupies an exceptional place. According to some writers in the medical journals, the operation is almost unknown in many places.

Epileptic Convulsions with very Slow Pulse.

Dr. Charles Boyce reports the following interesting case in the *Brit. Med. Jour.*, March 8, 1884:

E. B., aged 28, a strong, muscular man, had served for a short time in the county police force, and claimed his discharge two months ago, but

not from any ill health. He had never received any injury to the head. He suffered from syphilis two and a half years previously to his death. On November 25th, whilst talking to a friend, he suddenly felt a violent pain shooting through the right side of the head towards the posterior part, and, during the act of exclaiming, fell down in a convulsive fit. He soon recovered consciousness, and returned home, but, not feeling very well, went to bed. During the night, vomiting came on, and soon afterwards another convulsion. The vomiting and convulsions were repeated frequently before I saw him early on the morning of November 26th. I was informed that vomiting persisted after everything taken into the stomach, and retching continued after the stomach was empty. The tongue was clean; the bowels constipated; the pupils dilated, but acting to light. The *tache cérébrale* of Trousseau was marked; the countenance was pale; the ears were of a dull purplish color, exhibiting dilated veins and capillaries; the pulse was 24 per minute. I was informed that complaint had frequently been made during the last two months of pain in the head. I had the bowels well opened with an aperient; but no medicine which I administered was able to arrest the vomiting. Accordingly, beef-tea enemata were given.

November 27th. He passed a very restless night. Vomiting and retching were less frequent. Convulsions occurred every few minutes, whether the patient were asleep or awake. A small quantity of urine which was passed yielded, on examination, no albumen nor sugar. The pulse in the morning was 14, in the evening 24; respirations 36. During my morning visit, an epileptic convulsion took place. Tonic and clonic spasms were present. On the return of consciousness, the face becomes suffused, and the patient asked where he was. I happened to be recording the pulse immediately prior to one of these fits, and observed that it was totally absent for fifteen seconds. During the fit, it was exceedingly slow; but afterwards it beat for a few minutes with greater frequency, averaging 37, and gradually fell again to 24. On November 28th, the fits were still very frequent. He had retained a small quantity of fluid nourishment and medicine (iodide of potassium). The pulse in the morning was 37; in the evening 24; respirations 37. The patient died seven hours after the evening visit.

During this short illness, the patient made frequent complaints of want of air, asking for the windows and doors to be left wide open. Percussion of the head elicited pain in the inferior and superior postero-parietal regions, but not in other parts. Such pain, says Dr. Alexander Robertson, is often associated with disease of the skull, generally syphilitic. The congested state of the auricle, which showed up vividly in contrast with the pallid face, may have been symptomatic of some vascular excitement in the new growth, or of the cerebral membranes; and the *tache cérébrale* points to the same. The late Dr. Laycock, after a careful study of the symptomatology of the ear, came to the conclusion "that the states of the circulation, nutrition, and development of the tissues which make up the ear-lobule and cover the helix very commonly coincide with similar conditions of the encephalic tissues." (*Med. Times and Gaz.*, 1862.) The local lesion upon which these well-

defined symptoms were dependent may be pretty accurately shadowed forth from a reflection upon the physiological phenomena. The cardiac centre was involved, bringing into play the inhibitory action of the pneumogastric nerve; the pulse registering at times only 14 per minute, and being absent altogether occasionally for fifteen seconds. The pupils were dilated, showing that the centre in the brain possessed of the power of producing this symptom was probably encroached upon, as was also the respiratory centre, the respirations being 37, whilst the pulse varied from 14 to 24. Death resulted when the "nœud vital" of Flourrens was extensively involved. The history of syphilis leads us to suspect the gradual formation of a gummatous or hyperplastic neoplasm, and its situation evidently the floor of the fourth ventricle or its immediate neighborhood. The case was seen with me by Mr. George Sankey, who confirmed the diagnosis.

Multiple Cutaneous Ulceration.

In the number of the *American Journal of the Medical Sciences* for January, 1884, Dr. I. Edmondson Atkinson records a case of universal interest and almost unique character, which is closely related to that rare and remarkable disease known as symmetrical gangrene.

The symptoms were briefly a papulation and vesiculation, followed by a very superficial destruction of the epidermic structures and the most external dermal tissue. This was followed, more or less rapidly, by ulceration of progressive character, so that, in the highest degree, in a very short time, not only muscle, fibrous tissue, and cartilage, but even bone was destroyed. At no point was there gangrene in mass, if we may exclude the secondary destruction of bone, but, on the other hand, rapidly progressive and molecular gangrene. This ulceration, while showing a tendency to affect similar parts of corresponding members and regions, could hardly be termed symmetrical. The right side of the face suffered much more severely than the left, while the left upper and lower extremities were decidedly more affected than those of the right side.

The extent to which motion and sensation were impaired was indeterminate. The child lost the power of locomotion, but whether from diminished nerve influence directly, or from increasing general debility was not evident. Certainly there was no complete paralysis. Similarly with sensation, it was difficult to determine the true condition. That there was abnormal sensation was certain, but whether there was itching or paresthesia was a matter of doubt. There were no scratch marks, or was any expression of pain elicited upon handling the parts. On the other hand, there can be no doubt that the sensation of pain was decidedly blunted, as shown by insensibility to quite rough usage, and by the violence with which the child bit and rubbed her extremities, even to the production of lesions and the copious discharge of blood. This bluntness of sensation extended beyond the area of lesions, and amounted to a decided numbness. Distinct symptoms of vaso-motor disturbance were not observed; the description of the mother, however, that the extremities became dry and wrinkled, is

of significance, though it must be admitted that this was not observed while the child was under treatment. The color of the child's skin would also doubtless interfere with the recognition of vaso-motor phenomena.

As causes of this remarkable condition, Dr. Atkinson was able to include mercurial intoxication, and that from ergot or other medicaments which occasionally excite gangrene or destructive ulceration in those into whose bodies such agents have been introduced.

Dr. Atkinson thinks there can be no doubt that this disease belongs to the group of affections which the late Oscar Simon first named "multiple arthritic gangrene." According to Simon, it attacks, almost exclusively, children between one and two years old, and begins with vesicles which dry into scabs. These fall off, and leave a loss of substance of varying depth, in some cases even reaching to the bone. In all cases, cachexia may be recognized. He regards the process as a gangrene produced by a cachectic thrombosis. It is not unlike the forms of gangrene produced by ergot, morphia, or in the course of diabetes, typhus, or in paraplegics. The prognosis is good. The treatment should be principally of a tonic character.

In the absence of definite knowledge of the pathogenesis of these and kindred lesions, and in view of the unmistakable vaso-motor disturbances observable in the more pronounced forms of the affection known as symmetrical gangrene of Raynaud, Dr. Atkinson thinks we can do no better than provisionally accept the theory of Weiss, according to whom the disease is a neurosis, in which the vaso-motor centre is, from whatever cause, readily thrown into a state of hypertonus; the importance of the symptoms depending upon the dignity of the parts upon which the vascular spasm is developed. Contraction of the cutaneous arteries will produce a bloodless condition of the skin. By venous spasm is produced local cyanosis, and by contraction of the vaso-dilators local active hyperæmia. Similarly, by vascular spasm of those portions of the posterior columns standing in functional relation with the skin, will be produced nutritive disturbances of the skin and epidermic structures.

An Effective Appliance for Symphyseal Fracture of Lower Jaw.

Dr. W. J. Naismith thus writes in the *Lancet*, December 8, 1883:

On July 30 I was called, in consultation with Dr. Hewitt, of Prestwick, to a young lady patient of his, who had sustained a severe carriage accident, having been violently thrown out of a cap-sizing croydon while taking a sharp turn in the road. There was a condyloid fracture of the left humerus, which was put up in the usual manner; but, in addition, the lower jaw was fractured through the symphysis, the two segments being freely movable, and there was a transverse wound about two inches in length requiring two or three stitches, just over the mental protuberance. The wound did not communicate with the fracture. Now, what we wanted was an appliance for keeping the jaw at rest, which would also permit of free access to the wound for dressing purposes.

The ordinary gutta-percha or other moulded splints were out of the question—first, because the cutting of such a hole in the splints as would have been necessary for the wound would have practically destroyed its efficiency, and, further, we were convinced that the nervous excitable condition of the patient would not tolerate any such weighty apparatus. The lower incisors, broken across and loosened, could not be utilized for ligature, and the neighboring teeth were of such shape as to afford no hold either for silk or wire. A carefully applied four-tailed bandage quite failed to afford the necessary support to the fracture, after a fair trial of about twenty-four hours, the parts evincing much mobility, and the patient complaining of the grating of the broken surfaces. In looking over some India-rubber appliances, it struck me that a Hodge's pessary, if bent and adapted so as to comfortably enclose the chin, sufficiently padded by having a long strip of lint about an inch in breadth whipped round it, and retained in position by tapes sewn to its angles and fastened, two over the head and two round the neck, after the manner of the four-tailed bandage, might supply the conditions aimed at—namely, support of the fracture and access to the wound. This idea was carried out, and with such complete success as to seem worthy of record in the columns of the *Lancet*. Grating of the bones and restlessness ceased immediately on adjustment. position was admirably maintained throughout the progress of the case, and free access was ensured to the superficial wound. The "Hodge" to be employed should be of good size, and bent so as to allow the chin to protrude through its ellipse. Thus one bar is moulded so as to support the fracture anteriorly, the other steadies it from below, while the rounded ends afford admirable lateral pressure on each side, at a point in front of the angles of the jaw. To these rounded ends of the pessary the tapes are sewn, two on each side, over the padding (the variety of tape I used was the strong one-inch breadth used with plaster for limb extension by weights), and these tapes were secured over the head, or to a fillet, and round the neck by small buckles, which readily admit of alterations being made in the firmness of the adjustment. In the absence of buckles, the tapes may be sewed or pinned together till these can be procured. A little cotton wadding inserted here and there under the tapes to obviate any discomfort from pressure, completes the appliance.

For fractures of the inferior maxilla at or near the symphysis, with or without wound, the Hodge's pessary seems well adapted. It can be bent to fit any size of jaw, and in the qualities of comfort, lightness, and coolness compares very favorably with the solid cumbersome appliances included under the head of moulds. It is always at hand, easily carried, and does away with all necessity for the labored measurements, cuttings, and mouldings incidental to leather, poroplastic, or gutta-percha. Cases there are, of course, of this injury which do very well with an ordinary four-tailed bandage or some of its modifications, but that these do not always give satisfaction, the case I have narrated sufficiently proves, and it is well to have a more trustworthy resource to fall back upon. I desire to add, in conclusion, that our case was subsequently seen in consultation by

Professor George Buchanan, of Glasgow, who was pleased to express his unqualified approval of the method of treatment adopted.

A Case of Supposed Dislocation of the Tendon of the Long Head of the Biceps Muscle.

In the *American Journal of the Medical Sciences* for January, 1884, Dr. J. William White records a case of this very rare form of luxation, and reviews the history of the few other cases in which this accident is supposed to have occurred. He finds that the recorded evidence of the occurrence of dislocation of the tendon of the long head of the biceps muscle may be divided into two general classes:

1. The reports of clinical cases in which certain symptoms were referred by the writers to this displacement, but in which its existence was not otherwise confirmed.

2. The reports of cases in which the tendon of the biceps was found luxated at an autopsy, or during a dissection, but in many of which no clinical history was obtainable.

The study of the literature of the cases recorded leads to the conclusion that although for more than a hundred years, cases of supposed luxation of the tendon of the long head of the biceps muscle have been reported or alluded to by surgical writers, yet they have been so poorly observed or so carelessly described, that they fail altogether to carry conviction; the one case (Soden's), which possesses any strong element of probability being itself open to reasonable doubt.

The symptoms in Dr. White's own case, which led him to the conviction that there had been true traumatic luxation of the bicipital tendon, may be enumerated as follows:

1. The recognition of the bicipital groove, empty, which, if its existence be admitted, is pathognomonic.

2. Recognition of the tendon itself.

3. The inward rotation of the arm.

4. A slight depression under the tip of the acromion, a prominence of the shoulder in front, and a flattening behind.

5. Diminution in the vertical circumference of the shoulder.

6. Shortening of the arm as measured from the tip of the acromion, to the external condyle.

7. Elevation of shoulder, tilting up of acromion, and elongation and narrowing of the axilla when the arm was carried upwards.

8. The peculiar depression situated over the bicipital groove.

9. The line of ecchymosis following and strictly limited to the course of the biceps muscle.

10. A creak or "squeak," heard distinctly on carrying the elbow away from the side.

11. Flexion of the forearm on the arm was painful, the pain being sharp, lacerating, and felt at the front of the shoulder; flexion during supination was much more painful than flexion during pronation.

12. When extension of the forearm was attempted, a tense line along the edge of the biceps could be both felt and seen.

13. The pain felt over the joint was also felt along the line of the biceps as far as its insertion, and the patient still has a "drawing" sensation over that region.

14. The arm was preternaturally mobile for some time after the accident.

15. The position of the patient after the accident.

16. The character of the force producing the difficulty.

The rationale of these symptoms is very fully explained.

Wound of Knee-Joint—Application of Permanent Antiseptic Dressing—Recovery.

Dr. M. O. Bunn thus writes in the *N. C. Med. Jour.*, March, 1884:

The following case illustrates quite forcibly the value of antiseptics in the treatment of incised wounds of joints:

On December 4, 1883, was called to see a negro boy, æt. 10 years, who had just cut his knee with a drawing-knife while attempting to make an axe-handle. Found him suffering considerable pain, and on examination found that the knife had entered the knee-joint, on the outer side, just below the level of the patella, slightly injuring that bone in its upward course, and very nearly severing the flap of tissue (which was about one and a half inches in diameter, and of circular form) from the leg.

Having none of the paraphernalia of Lister at hand, we concluded to extemporize. The wound and leg were cleansed as thoroughly as possible, first with castile soap and water, and afterwards with a carbolyzed solution (1 part acid in 40 of water). A sponge saturated with the lotion was then placed over the wound, while the other appliances were being prepared.

Procuring some cotton batting, it was placed between the folds of a handkerchief, and thoroughly saturated with the carbolyzed solution. Bandages of white homespun were treated with it also. Then, after placing several carbolyzed silk sutures into the lips of the wound, coaptating it as evenly as possible, the whole knee was enveloped in the batting, from which the excess of water had previously been pressed. Upon this the bandages were applied, at first loosely, then gradually more snugly, until the limb was covered by six or seven thicknesses of cloth, from about six inches above the knee to about six inches below it. This completed the dressing.

Fearing a stiff knee, and wishing to keep the boy quiet, a long Liston splint was applied, omitting the perineal strap, and the patient placed in bed, with orders to keep quiet. He did not develop any untoward symptoms, the temperature did not reach at any time over 101° F., and the dressing was not disturbed until the twelfth day after application. Upon removal repair was found complete, and not over a teaspoonful of discharge had accumulated in the batting. The knee was not stiff in the least, and the boy is now as well as ever, one month since the accident.

The case furnishes two important deductions:

1. We may secure good results without recourse to absolute Listerism, by careful attention to the thorough cleansing of parts before wounds are closed.

2. Even the country practitioner may not think it impossible or improbable to secure, in this class of injuries, union by first intention, if he will use properly the means at hand, supplemented by the

judicious use of antiseptics, and by careful attention to after-treatment.

Rupture of Bladder, Dislocation of the Knee, and Compound Fracture of Both Lower Limbs.

Dr. Cottenham Farmer reports this case in the *Brit. Med. Jour.*, March 1, 1884:

On July 4, I was called to an accident which had occurred at the local railway station. On arrival, I found a lad, aged fifteen years, in the following condition: He was blanched, and the surface of the skin was quite cold; he was conscious, and complained of great abdominal pain and an extreme desire to pass urine. There was tenderness on pressure over the lower part of the abdomen, and, on passing a catheter, about two ounces of bloody urine were drawn off, but without relieving his desire. The catheter was thereupon tied in, under the full impression that grave injury, probably rupture, existed. Further examination was then made, chloroform having been given. There was a compound comminuted fracture of the lower third of the right leg, with loss of blood from the wound, and dislocation at the knee-joint. There was also a compound and much comminuted fracture of the left leg.

The following treatment was at once adopted: Both wounds were covered with dry absorbent wool, and then the legs, to above the knee, were enveloped in Southall's pads. These were strengthened with soaked millboard splints, and the whole was firmly and evenly bandaged from the toes to above the knee-joints. The dislocation was then reduced. The boy was then carried to bed, and the legs placed in Lawrence's cradle-splints, and these were swung by ropes suspended from the ceiling, so as to ensure to the limbs the freest possible movement. Opium was administered during the night, and poultices were applied to the abdomen.

On the 5th, the patient complained only of abdominal pain. There was great tenderness over the pubes. The urine passed through the catheter less tinged with blood. Next day the urine was clear; there was still suprapubic pain.

On the 14th, the catheter was withdrawn, and he passed urine freely and with little pain. His legs had never given him the least discomfort; but, at the suggestion of my partner, on the 14th instant I cut open the bandages and exposed the limb. Never having seen a fracture so treated, I was astonished at its appearance. It looked quite natural; the wound had healed, nor was there even a trace of ecchymosis; the bones appeared firm and free from pain on pressure. The splints were reapplied on the 20th. Owing to a disagreeable smell, I opened and exposed the left leg, finding the following condition: The limb looked in every way healthy, but on its inner aspect, lying thoroughly exposed, and without the slightest signs of inflammatory action, was a large piece of the tibia (over two and a half inches in length). This I seized and lifted out of its bed, leaving a healthy-looking wound, which progressed rapidly towards healing.

On August 16, both legs were put up in plaster of Paris, and he left for home. He has since resumed his work.

The case may be of interest to surgeons, not only on account of the pelvic injury, but to the

satisfactory result of a plan of treating the most serious fractures, not as yet, I think, sufficiently recognized or adopted.

Glaucoma Treated by Forcible Tearing of External Nasal Nerve.

The *Edinburgh Medical Journal*, March, 1884, quoting from the *Annales d'Oculistique*, says:

Badal, encouraged by the cure of a case of ozæna associated with violent neuralgia of the upper and middle branches of the fifth, which followed a tearing of the nasal nerve, has for the last year treated all cases of glaucoma, in which operative interference seemed at all advisable, in the same way. The theory which led him to adopt this novel treatment is that "the increased tension is manifestly the result of a breach of equilibrium between the secretion and elimination of the intra-ocular fluids; we should therefore be able to remedy this by acting on the vasomotor or secretory functions, and we may be permitted to suppose, from analogy with the above case, that the elongation of the nasal nerve in preference to any other would produce the desired result;" and he adds that "this hypothesis has been confirmed by clinical experience." He prefers tearing the nerve, as this can be done very easily by merely cutting down in its vicinity, and seizing the tissues round about and including it with a hook, which is then made to tear its way out, the bleeding from the accompanying artery being so slight as to be of no consequence. When this operation is not effectual, Badal thinks the next thing to do is to stretch one of the other branches of the fifth. He observes that "whether the surgical trauma acts on the terminations of the ciliary nerves, as in sclerotomy, iridectomy, or Hancock's operation, or on the nerve trunk, as in stretching, the effect will be the same. But we may imagine that the chances of cure would depend to a certain extent on the number of nerve fibres involved." In this way he explains the superiority of iridectomy over a limited sclerotomy, and of the tearing of the nasal nerve over iridectomy. The cutaneous anæsthesia caused by the rupture of the nerve is too limited in extent to be of any importance. The results obtained are as follows: In 25 cases of glaucoma, not selected, but taken just as they came, the tearing of the nasal nerve produced tension in 19. In 20 of the cases in which the glaucoma was acute or sub-acute, the operation caused very speedily, and sometimes almost instantaneously, a cessation of the pain. In 4 of these cases iridectomy had aggravated the condition. In 4 cases a previous iridectomy, and in 6 a previous sclerotomy, had failed. Of 2 cases of acute glaucoma the cure was rapid and complete in 1, while in the other the vision did not return. In 6 other cases in which the vision had been for long lost or almost abolished, 3 recovered sufficient acuity to be able to guide themselves (!) Finally, in the cases in which the operation advocated failed, a subsequent sclerotomy or iridectomy was no more successful; and further, the tearing of the nerve never produced any aggravation in the existing condition, even when unsuccessful in affecting an amelioration. Badal recommends his operation for all cases of glaucoma, without exception, as the one most likely to have a favorable influence on the disease; and only in

very acute cases, where there is a very urgent indication to bring about a diminution in the intra-ocular tension, does he admit the advisability of combining it with any other procedure. Even this should be no more than paracentesis. From the above description it is clear that, should the results obtained by others equal those of Badal, the operation of tearing out the nasal nerve will not be long in being adopted as the principal cure for glaucoma.

On a Mode of Identifying the Upper and Lower Ends of any given Piece of Small Intestine.

Dr. R. Frank Rand contributes the following practical paper to the *Lancet*, December 22, 1883:

"It is confessedly difficult to determine the course, as between duodenum and cæcum, of any portion of the small bowel which may present when an opening is made into the abdominal cavity; as, for example, in a section made for the relief of intestinal obstruction. Operators have ere this passed feet of intestine through their hands, uncertain as to whether they were proceeding upwards or downwards in the direction of the length of the tube.

"In those cases where an opening is made into the abdominal cavity sufficiently large to admit the hand, the mesentery may be taken as a sure clue, if the attachment of its root be borne in mind. This attachment, it will be remembered, runs along the front of the spinal column in an oblique line from the left side of the second lumbar vertebra to the right sacro-iliac synchondrosis; it corresponds roughly with the long axis of the trunk. Above, it comes into relation with the upper end of the small intestine at the commencement of the jejunum; below, it leaves it at the cæcum. At the spine the two surfaces of the mesentery face laterally right and left; further out, their arrangement, like that of the bowel, is constantly varying. As we may speak of a right and of a left surface as regards the mesentery, so may we, none the less, as regards the bowel. It is difficult to identify the right and left sides of the bowel, but those of the mesentery are, at its root, self-evident, for here it occupies but some six inches in extent of length, whilst at its periphery it reins in some nineteen feet or so of tube. The right and left sides of the bowel having been identified, a knowledge of the proximal and distal ends follows in necessary sequence. The peritoneal cavity having been opened at any point in the anterior abdominal wall, the first piece of small bowel presenting may be seized; its long axis being held in the long axis of the body, and its attached mesentery being pulled out taut from the spine, the hand may be passed, guided by the mesentery, backwards to the spine, when it may be passed upwards and downwards without hindrance along its spinal attachment. If the bowel is being held in its true direction, the hand passed to the right of it will be conducted by the mesentery to the right side of the spinal column, and, passed to the left of it, it will be conducted to the left side; but should the apparently upper end of the bowel be not really so, the hand in passing to its right side will be conducted by the mesentery over to the left side of the spine, and, conversely, if passed to its left side will be conducted over to

the right; in either case the hand being passed upwards and downwards to identify the mesenteric root. Nothing can be simpler in practice, as may be found by making trial and test in the post-mortem room. I have no doubt this method has been used in the past, but having found no record of it, have thought it worthy of mention."

REVIEWS AND BOOK NOTICES.

BOOK NOTICES.

Medical Diagnosis, with Special Reference to Practical Medicine. By J. M. Da Costa, M. D., LL. D., etc. Sixth edition (revised). 8vo., pp. 967. Price, cloth, \$6.00. J. B. Lippincott & Co.

So long has this work been a favorite standard with the medical profession that it leaves little for the reviewer to do than to announce that a new edition has appeared. The whole of the text has been revised, and new matter has been introduced into many of the chapters. A number of woodcuts have also been added. These additions have brought the work up to the latest demands of science, and will undoubtedly secure for it a renewed welcome from the medical public.

A Manual of Psychological Medicine and Allied Nervous Diseases. By Edward C. Mann, M. D., etc. 8vo., pp. 699. Philadelphia: P. Blakiston, Son & Co.

It is doing considerable violence to the term "a manual" to apply it to a bulky, large octavo which weighs about four pounds! And when the author, in his preface, speaks of the "concise form" of his treatise, he must have had some ponderous folio of antiquity in his mind as a standard of comparison. There is a great deal, in fact, in his work which the general practitioner, desiring to learn the most in the least time, could well dispense with; but for those specially interested in the subject, this will be a recommendation.

The earlier chapters treat of insanity in general, its etiology, prevention, and diagnosis. The tests of legal responsibility are fully stated. The varieties, idiocy, dementia, and general paralysis are described, and the obscure questions of histological pathology in this connection are stated, if not answered. The second part has several excellent chapters on modern nervous diseases, the evolutionary development of the nervous system, and on the special diseases, dipsomania, hysteria, epilepsy, hysterio-epilepsy, chorea, vertigo, anæmia, neuralgia, etc. A chapter on the psychology of crime is replete with thoughtful views, well worthy the attention both of physicians and jurists. Several phototype plates and other illustrations add to the value of the work.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - - -	6.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

The COMPENDIUM, formerly published every six months, appears now *every three months*. It is compiled with special reference to being taken *with the Reporter*, and none of the articles which appear in our weekly are reproduced in our quarterly publication. It is made up exclusively from other sources.

Each number of the *Quarterly Compendium* contains 150 pages of reading matter, carefully selected from American, British, and European medical journals, with a special view to the wants of the American physician. It is on excellent paper, and neatly bound in pamphlet form, with full table of contents and index.

The price of the COMPENDIUM is 75 cents a number, or \$2.50 a year; and it will be found well worth it. But when taken with the REPORTER, we offer the two journals at the very low price of SIX DOLLARS, when paid for *strictly in advance* and directly to this office.

EXERCISE VS. DRUGS.

The leading minds in the profession are gradually and surely commencing to realize that the hygienic treatment of disease is entitled to a much higher place in our estimation than is usually accorded to it. A rational and intelligent combination of the use of drugs and hygiene is the ultimatum to which we should direct our efforts, and by so doing we will much more fully and satisfactorily accomplish our mission than by adhering to the blind, routine drug treatment of disease, which, though in reality a thing of the past, yet has many advocates in the profession.

Dr. S. Weir Mitchell's exalted reputation rests mainly upon a true conception and an intelligent carrying out of this principle, and the same may be said of nearly all the more eminent men in our ranks.

It is but common sense to believe that did all the organs of the body thoroughly functionate, so to speak, did they all perform their allotted tasks, disease would be unknown; and it is also well admitted that exercise is a most potent agent in maintaining the functional activity of these organs.

Hence, reasoning from these premises, it is but logical to infer that when any organ or system has become deranged, such exercise as will stimulate to healthy activity this particular organ or system, will do much to restore the healthy, normal standard.

We have known many cases of constipation that have persistently defied the use of an almost endless variety of drugs, to thoroughly yield to a series of brisk daily walks. One of the greatest evils of American life is the apparent antipathy to well-regulated exercise, which among our English brethren is so thoroughly believed in; for want of it, our organs refuse to perform their duty, they become torpid, and languid, and lazy, and we thus become easy prey to the inroads of disease.

When, therefore, a patient consults us and we find that he has some functional derangement of some organ or system, let us, along with our prescription, recommend such exercise as is best cal-

culated to increase the activity of this particular part. Exercise really means motion, and we can advise that which will serve to bring into motion the part that has been rendered functionally weak through the want of motion. For all classes, walking is pre-eminently the most beneficial of all forms of exercise; and since it costs nothing, it can be recommended to the poorest of our patients.

THE EDUCATION OF CHILDREN.

An attack upon the custom of sending young children to school was recently made by Dr. Howie, a physician of Liverpool, before one of the medical societies there. He carried his views so far as to say that no child under twelve years of age ought to be called upon to perform any kind of work, whether muscular or mental. That four hours *mental exercise* is enough, twelve hours in bed, four hours for meals, etc., and four for muscular exercise. That much as he believed in education as a means of national improvement, yet it would be better to leave the masses uneducated, than to train their minds at the expense of muscular strength and dexterity. Reading and writing, although extremely important, yet were not absolutely essential to the highest education; that facts themselves without the ability to think and speak correctly about them, are of but small advantage in mental training. Throughout the whole course of a child's school career, most of the subjects of study are quite beyond his intelligent grasp, unless he is specially precocious. He then described, at some length, the influence which close confinement in school-rooms had upon the health by inducing a tendency to frequent bronchial catarrhs, which in children of phthisical history will ultimately lead to that disease, and quoted several cases from his own experience in support of this. He also spoke strongly in favor of the half-day system of schooling. In our elementary schools it is not so much actual overwork as excessive stimulation of the growing brain, which leads to its far too rapid growth to remain healthy.

Such was Dr. Howie's argument; and although

we think that in his enthusiasm he carried his recommendations too far, on the other hand we hold that he was arguing on the right side. The anxiety that many parents and teachers have to push very young children to the utmost of their powers, is almost certain to sacrifice the very object at which they aim. The precocious little boy or girl usually turns out to be the stupid, inactive man. Education in young children must be at the same time amusement, or it is valueless and probably harmful. A repulsive task should never be set for a child. Hence the great superiority of the methods of Pestalozzi and Froebel.

PREJUDICE AGAINST MEDICAL MEN.

It is somewhat remarkable that even in the most intelligent circles in England there is a distrust of medical men. This is seen in the frequent suits at law which are instituted against even eminent members of our profession, and by the tone of some of the ablest newspapers. In our last mail, for instance, we note a suit against the distinguished alienist, Dr. Forbes Winslow, and another against a Birmingham physician of high standing.

The plaintiffs in both cases lost, but the unpleasant notoriety and expense of defending themselves remained with the physicians. In fact, recently Sir Andrew Clark, M. D., has protested against this outrageous prejudice.

Its presence is also shown in a letter admitted to one of the most important London papers, *The Standard*. This letter, purporting to be from "A Young Wife," accuses medical men of intruding on the confidences which ought to exist between husband and wife alone, and consistently ends with the suggestion that women should be attended only by women doctors.

The charge which "A Young Wife" prefers is, it does not need to be said, unfounded; nor that medical men, as often as they can without injury to their patients, purposely avoid discussion of details that might seem unbecoming to "Young Wife." When, however, safety to life and health demand that the medical attendant must obtain in-

formation which he can only get by means of questions that would come more appropriately from a husband, then stern duty commands the proceeding; but to call this an unjustifiable intrusion on the marital relations, is as cruel as it is ridiculous.

All such prejudice arises from ignorance, and will disappear by a more general cultivation of the masses in anatomy and physiology.

SUBJECTS FOR THE AMERICAN MEDICAL ASSOCIATION.

Of the subjects which urgently demand the serious attention of the American Medical Association, we name as paramount those which are tending to the degradation of the profession in this country. It ought to act solidly and with determination where these are concerned.

One of these is the *debasing of medical education* by certain Western colleges, and by the efforts of some State Legislatures, to make it part of a free course. Such colleges as offer improper inducements to students, or who pass them on incomplete courses, or who furnish diplomas to manifestly unprepared students, should be publicly branded and their names pilloried.

Another subject for immediate attention is the studied contempt cast upon the profession by some transatlantic steamship lines, especially the Red Star Line, which has put surgeons in the second cabin. The other lines have not yet gone so far, but undoubtedly will soon follow suit if the American profession accepts in silence this insult.

The Red Star Line is owned in this country, and its surgeons are American physicians, although it sails under the Belgian flag.

We say, here are two points calling for immediate action. They should be approached with energetic measures. The colleges should be pilloried, and a demand made upon the steamship lines to restore the surgeons to their proper sphere, or the association would recommend all its members and all the profession to throw their influence against its business. Such corporations have only one vulnerable point, only one heel of Achilles, and that is their pockets. Respect for the feelings of educated men is utterly unknown to them.

HOW TO READ PAPERS BEFORE MEDICAL SOCIETIES.

Since the season of medical society meetings is fast approaching, a few words on this subject will be timely. In looking over the various papers that are annually read at the different State Societies, one is forcibly struck with many unfortunate features about them. Oftentimes there is little or nothing new in them, their titles are frequently irrelevant, and they are altogether unnecessarily lengthy. When a man has something really new and valuable that has occurred in his experience, the like of which has never been put upon record, or of such a nature that, even though recorded before, an accumulation of similar records would seem desirable, then by all means he should either publish his experience in a medical journal, or present it in the form of a paper before his State Society; but, to repeat, let him have some definite end in view, let him be positively sure that his paper will bring enlightenment to the profession. When he has settled this point, he should fulfil his purpose in as few words as possible. It is both tiresome (to his auditors) and unprofitable, to read long published extracts bearing on the subject in hand; for by simply referring to where such matter may be found, all those who so desire can read it for themselves, while those who are already familiar with the writings quoted from, will not be annoyed by uninteresting repetition. In a word, then, be sure you have something new, say it in as few words as possible, avoid long quotations, and give your paper a relevant title.

NOTES AND COMMENTS.

Gallic Acid in Hemorrhage from Urinary Organs.

Of all the remedies usually recommended for this condition, Dr. Lionel S. Beale (*Lancet*, March 15), prefers gallic acid, which he says seldom disagrees in any way. Some patients complain of its taste, but it is generally well borne by the stomach. It does not cause constipation, and even when the crystals are swallowed in a state of suspension in water or mucilage no inconvenience results, and the stomach is not disturbed by their presence. The glycerine of gallic acid is, how-

ever, the most pleasant form in which to prescribe the remedy. This contains one part of gallic acid in four. Forty minims will contain ten grains, and may be given in distilled water, peppermint, orange, or other water. But it is most essential that the patient should persist in taking the doses regularly for several days. Gallic acid is absorbed by the blood and passes away unchanged in the urine, and it is probable that it acts directly on the parts from which the bleeding is taking place; and therefore a certain strength of solution is necessary to get the good effects, and this can only be obtained by its persistent introduction into the stomach, and so into the blood at short intervals of time. He has given gallic acid in ten-grain doses every three hours without intermission for three weeks, no objection having been made on the patient's part. Whether much larger doses would be absorbed he doubts; but he is not aware to what extent the remedy may be pushed, nor does he know in what respect very large doses would be deleterious. On these points he would be glad to learn the experience of other practitioners who have largely employed the remedy. He has generally found that the desired effect has resulted after ten-grain doses had been kept up for three or four days, and in cases where the bleeding did not actually cease, it was certainly well under control. In several of those painful cases of hemorrhage from fungous growth, the bleeding was much lessened and the fatal result postponed; in some of his cases he should say that death was due rather to exhaustion and weakening of the general health than to the hemorrhage. He therefore commends this remedy in the cases of hemorrhage to which he has referred, and he prescribes it with confidence, so that its use may be steadily continued until its beneficial action is clearly established.

Rupture of Ligamentum Patellæ and Fracture of Patella.

The co-occurrence of these two injuries is sufficiently rare to render interesting the case which Dr. M. Gardiner reports in the *Edinburgh Medical Journal*, March, 1884:

The patient was a heavy, powerful man, who while at work tripped over a bag and fell heavily on his knee on the floor. While falling he had tried to recover himself by a backward jerk, but had failed to do so. Trying to rise, he found he was not able, and when set on his legs he could neither walk nor stand without assistance.

On examination, a large, tolerably definite swelling was seen over the knee-cap. Touch

proved this to be fluid. The movements of the joint were limited, extension being almost abolished. Fluctuation was also to be felt on each side of the ligamentum patellæ, but the attachment of that structure could not be defined, and the finger felt as if it could pass right in between tibia and femur. Rupture of the ligament was therefore diagnosed. Owing to the history, attention was next directed to the patella itself, patient stating that he thought it was broken. On account of the swelling the patella could scarcely be defined, and owing to the rupture of the ligament its superficial area did not seem increased. Fracture was, therefore, only suspected, but not absolutely diagnosed.

The swelling of the knee and surrounding tissues increased, but finally subsided under the treatment adopted, and on the fourth day the joint had so far returned to its normal state as to allow of a thorough and perfect examination. This proved the suspected fracture to be real.

It is difficult at first sight to account for both rupture and fracture, but the probability is that the backward jerk described by patient ruptured the ligamentum, and that the blow on the floor fractured the patella. Effusion was very rapid and very extensive, seen principally over the patella and on both sides of the head of the tibia. Hot fomentations applied at first did not seem to answer well, but the application of dry cold proved of great service in reducing both swelling and pain. The case is doing well.

Uterine Displacements and their Treatment.

Pessaries are always suggested to the mind when a displacement of the uterus is made out, yet we all know that they are oftentimes not only inefficient, but in some cases are absolutely injurious. On this subject Dr. Robert Bell, writing in the *Edinburgh Med. Jour.*, March, 1884, says: "There are certain conditions of the uterus where the introduction of a pessary would produce much more pain and a more serious array of symptoms than the malposition, if left alone, would tend to do; and it is in such circumstances that the tampon, in my experience, has proved of such eminent service. We are all familiar with the great power glycerine exerts in abstracting fluid from an oedematous tissue; but it may not be equally well known that this power is very much enhanced when the glycerine contains alum in solution. Moreover, the presence of alum, by virtue of its astringent properties, gives tone to the vaginal wall and the uterine wall and supports. The tampon, therefore, when saturated with a solution

of this salt in glycerine, and properly applied in flexions or versions, acts in three different and beneficial ways—1st, as a support; 2d, as a depleting agent; and 3d, as an invigorating agent to the uterus and vagina."

He states that the tampon varies in size with that of the vagina, and that it is as well to attach a piece of fine cord to it to make its withdrawal easy of accomplishment. The proportion of alum to glycerine is one in eight, and to every eighty ounces an ounce of boracic acid is added to keep the tampon from becoming foetid, which it otherwise would do if the discharge from the uterus is at all copious. The tampon itself is composed of carded cotton. He would therefore recommend this method of treatment in cases where the use of the pessary is inadmissible.

Multiple Hepatic Abscesses in a Boy Aged Eleven.

To the Clinical Society of London (March 14, 1884), Dr. Samuel West read notes of this case: A Jewish lad, aged 11, who had never lived out of London, had a rigor on January 21, and pain in the right hypochondrium. He was brought to a hospital on February 20, with evident hepatic abscess, extremely ill, and with a temperature of 105°. On February 23, a large abscess was aspirated, and thirteen ounces of greenish sweet pus were removed. Four days later a free incision was made, and seven ounces and a half of turbid purulent fluid escaped; a second abscess was discovered and aspirated, when one ounce of blood-stained pus was removed. On March 6, the two last swellings were again prominent, and were freely laid open, and a drainage-tube inserted. On April 9, a fresh abscess was found, explored, and freely laid open. From this time convalescence commenced, interrupted only by a diffuse abscess in the abdominal walls, which healed alone on being opened and washed out. The points of the case were the following:

1. The age, 11 years.
2. The number of abscesses, three or four, and probably more.
3. The absence of any assignable cause.
4. The great relief by evacuation.
5. The rapid fattening during convalescence.

Cuvier's Brain and Cranium.

From the *Rev. de Therap.*, December 1, 1883, we learn that in a recent communication to the Société d'Anthropologie, Dr. Georges Hervé quoted some details from a report on the illness and autopsy of Cuvier, which was addressed to the So-

ciété de Médecine Pratique by Emmanuel Rousseau, and inserted in the *Lancette Française* for May 26, 1882. According to this report, the weight of the encephalon was found to be 3 pounds 11 ounces and 4 drachms, or 1861.20 grammes; while the official *procès-verbal* of the autopsy, signed by A. Bérard, fixes it at 1882.96 grammes. The cerebellum weighed 191.40 grammes. The dimensions of the cranium were taken prior to the autopsy, and are as follow (the hair having been previously shaved off):

1. The great horizontal circumference 65.45 centimetres.
2. The median inco-frontal curve, 36.69 centimetres.
3. The transverse supra-auricular curve 40.60 centimetres.

The examination of the brain revealed, besides a truly extraordinary abundance of the cortical substance, a great amplitude of the lateral ventricles, which contained a small quantity of slightly turbid fluid, their walls seeming of a mucous nature. This fact, joined to the enormous dimensions of the cephalic extremity, and the thinness of the walls of the cranium, would lead to the supposition that Cuvier had been—as indeed it was stated that he had—the subject of hydrocephalus in his childhood.

Miliary Aneurisms of the Stomach.

The causes of fatal hematemesis (says a foreign exchange) are fairly well known, but some of the details of its pathology still require elucidation. M. Gallard has recently written on the subject of miliary aneurisms of the stomach. In 1875 he made some observations on simple gastric ulcer, and as a rule found sufficient anatomical cause for death where that had ensued. But in 1876 he came across two cases in which rapid death from hemorrhage had occurred without any other lesion being found than ulceration of a miliary aneurism situated on one of the branches of the gastric coronary artery. He has recently discovered a third instance in a man aged forty-eight years who died suddenly from hematemesis. The mucous membrane of the stomach showed at the great curvature and near to the cardiac orifice a small ovate tumor, the size of a haricot bean. There seemed to be no doubt that this was an aneurism which had ulcerated at its summit. Goupil, in his thesis on the "Generalization of Aneurisms," quotes two cases of miliary aneurism of the stomach in old people, which, however, had not led to any symptoms. Dr. Douglas Powell has published a case in the *Transactions of*

the Pathological Society for 1878, which occurred in a patient the subject of phthisis.

Contagiousness of Typhoid Fever.

Apropos of this interesting question, Dr. J. W. Long thus writes in the *Nashville Jour. Med. and Surg.*, February, 1884:

This disease is generally conceded to be *slightly* contagious—i. e., the specific poison having its abode in the alimentary canal, is carried off in the fecal matter, and after leaving the body goes through a process of development, which fits it for contaminating other persons—through the medium of the air, water, milk, etc. Some of the feces almost always soiling the patient's linen, makes the washer-woman more liable to take the disease than any one else. This then, is not strictly a *contagious* disease—but more properly belongs to Prof. Maddin's class of *contagio-miasmatic*.

Statistics of 35 cases occurring in private practice—showing mainly the tendency to plurality of cases in a family:

No. families.	No. cases in each.	Fatality....	Causes of death.
1	5	2	Sudden failure of heart in 1.
1	4	1	Gradual failure of vitality in 4.
3	3	3	<i>Perforation</i> , or tumor or abdomen bursting internally in 1.
3	2		
12	1		

I cannot say positively, whether or not the 2d, 3d, 4th, or 5th case, occurring in the same family, was produced from the 1st, and so on in succession; but this I do know, that the time between the occurrence of any two cases (in the same family) was from "one to four weeks"—being Dr. Bartholow's estimate of time necessary for fever to develop after system is infected by the specific poison.

A Case of Athetosis.

A case of this rare nervous disease, first defined, we believe, by Dr. Wm. A. Hammond, was described recently by Dr. Dyson, of Sheffield, England. It is characterized by inability to maintain a fixed position. The case in question was one of the right arm, and in a much less degree, of the right leg. The patient, a girl aged eleven years, had scarlet fever three months ago. About six weeks ago, she was seized with an apoplectic form of attack, in which there was loss of consciousness, paralysis of right side of the face, right side of the tongue, right arm, and right leg. She was

confined to bed for a fortnight, and as the paralysis passed off, the present condition of the right arm gradually supervened. Sensation is but slightly affected. The movements are slow and deliberate, and intensified by exertion, and are exactly those described in typical cases of *athetosis*. There was no history of rheumatism. The heart is healthy. The urine presents no abnormal conditions. In this case there is a history of the girl having been bullied by the school board attendance officers to return to school too soon after the attack of scarlet fever.

Uses of Copper Sulphate.

The value of this article in gynecological practice has lately been urged before the Paris Académie de Médecine by M. Charpentier. He read a paper on "Sulphate of Copper in Obstetrics," and deduced the following conclusions:

1. Sulphate of copper is an antiseptic of the first order, and renders signal service to obstetricians.
2. It is cheap, and easily used by the most inexperienced hands.
3. Of complete innocuity whether employed under the form of intra-vaginal injection, or intra-uterine.
4. That sulphate of copper, from its astringent properties, could advantageously replace perchloride of iron.
5. The solution employed should be a one per cent.
6. The solution at this strength might be continued eight or ten days without producing more than a diminution of temperature, and a fall in the pulse.

Eczema Capitis.

From the *Edinburgh Med. Jour.* we learn that in the ordinary eczema of the head in children, so commonly met with in dispensary practice, after two or three thorough cleansings, the daily application of the following salve nearly always suffices to obtain a rapid and lasting cure:

R. Acid. salicylic, gr. x.
Tinct. benz., ℥. xx.
Vaselin, ʒj.
M. Ft. ung.

On other parts where a soft, easily melting salve such as this is not suitable, or where a firm dressing or a drying effect is desired, the following paste should be rubbed on:

R. Acid. salicylic, gr. xix.
Vaselin, ʒj.
Zinci oxid, Amyli, ʒj.
M. Leniter terens, fiat pasta. aa ʒ ss.

Peripheric Neuro-Tabes.

In the *Brit. Med. Jour.*, March 22, 1884, we read that at a meeting of the Société de Biologie, held in February, 1882, Dr. Déjerine made a communication on some lesions of the peripheric nerves found in locomotor ataxy. He said that some of the symptoms, such as the occurrence of localized areas of anæsthesia and hyperæsthesia, were due to a peripheric neuritis, and not to a degeneration of the posterior nerve-roots, or of the spinal cord. More recently the same author has attempted to prove, at a meeting of the Académie des Sciences, that all the symptoms of tabes can be present without myelitis. In two cases where the diagnosis had been made without hesitation, he found after death that the nerve-roots and spinal cord were quite healthy, but that many peripheric nerves presented evident signs of parenchymatous neuritis.

Severe Conjunctivitis from Whisky Thrown into the Eyes.

In the *Brit. Med. Jour.*, March 22, 1884, Mr. G. A. Brown communicates this case. The patient was seen the day after a glass of neat whisky had been thrown in his eyes. Both eyes were closed, the lids were much swollen, with yellowish sanious semi-purulent discharge. The lower half of each cornea was covered with a diphtheritic membrane, which peeled off, leaving the cornea clear. The conjunctivæ were deeply injected, and there were slight ecchymoses, but no chemosis. There was much pain and intolerance of light. Under belladonna fomentations, and syringing with a warm weak solution of boracic acid, improvement rapidly took place. In two days the membrane had disappeared, and the conjunctivitis and photophobia soon subsided, so that the man was well in a fortnight.

To Destroy the Nerve of a Tooth.

From an exchange we learn that the preparation used by dentists to destroy the nerve of a tooth is the following paste, which is usually made in minute portions as wanted:

Arsenious acid,	3 parts.
Morphia sulphate,	2 parts.

Creasote—a sufficient quantity to make a paste.

When used, a minute quantity is introduced in the tooth cavity, which has been previously dried with absorbent cotton, and afterward a small plug of cotton moistened with collodion is placed over it.

CORRESPONDENCE.

Will-Power in Child-Birth.

EDS. MED. AND SURGICAL REPORTER:

February 29, 6 a. m. I was summoned to Mrs. M—, a primipara, aged twenty-four years, of German parentage, short, robust, healthy-looking. I found the patient sitting on the side of the bed. When I inquired what they wanted with me, the nurse said that when the messenger started for me she was having real hard pains, but upon my arrival, and before I entered the house, they stopped. I remained about an hour and a half, and still she said she had no pains, although I noticed an occasional frown indicative of slight pains. I administered $\frac{1}{4}$ grain morphia sulph., and returned to my office (about three miles distance), with instructions to send for me immediately on the appearance of labor pains. At 8.30 p. m. a messenger came and said that they wanted me to come quickly. Upon entering the house, the nurse told me that the waters had broken about 7 o'clock. She was having considerable pains, and upon examination, I found the os uteri dilated to the size of a silver half-dollar, and yielding, the fœtus not yet having entered the superior strait. After about an hour's apparent labor pains, I made another examination, and to my surprise, found that labor had not progressed a particle. I remained all night, and during that time made four or five examinations; and at 7 o'clock a. m., twelve hours after the water had broken, no progress had yet been made in labor—the os remaining about the same, the pains were short and frequent, but at regular intervals. She was up and down frequently, with a disposition to avoid any position that would make the pains worse; and as I have always allowed my patients the greatest possible latitude, not restraining them till the very last moments of labor in a majority of cases, I did not think it necessary to depart from the rule in this case.

In the morning I returned to my office for about two hours and a half, and on my return found no change; and she remained about the same throughout the day, at times complaining a good deal of her back.

Notwithstanding the administration of several large doses of quinia, and afterward the fl. ext. of ergot, entreaties and encouragement, no apparent progress was made until about 7 o'clock p. m., March 1, when she became more restless, but persisting in having her own way; and as my stock of patience was about exhausted, I spoke a little harshly to her, and told her that she must resume the recumbent position, and try and help herself a little, or she would kill herself and the child also. She asked two or three times to be allowed to get up, as she could not stand it that way; but I had taken my stand, and was determined to maintain it for a while at least. And the nurse seeing that I had broken the ice, as it were, proceeded to chastise her, and give her a piece of her mind; and, as if by magic, the pains began to get stronger and more like labor pains, the os gradually to dilate, and in a few minutes the vertex had fairly entered the superior strait, and in one hour and fifteen minutes

labor was completed, giving birth to a male child weighing about nine pounds. The after-birth came away without any trouble in a few minutes, and she convalesced without an unfavorable symptom, and remarked afterwards that it was not so bad as she thought it would be.

I am not prepared to say how much longer this woman could have held control of her delivery, but I am led to believe that it would have been many hours, had I not been a little harsh, and brought her to realize the danger that she was liable to bring upon herself.

I notice the report of a similar case in the Peoria (Ills.) *Medical Monthly*, by J. B. Ebert.

In a practice of 25 years I have not met with a similar case, and was not a believer in such a decided will-power over labor as was manifested in this, and therefore am prompted to report this case.

To sum up: With apparent hard labor pains for twenty-four hours, the os uteri dilated to the size of a silver half dollar, and larger at times, the head presenting loosely in the superior strait, the patient restless and uneasy, apparently trying to avoid the pains, and after being scolded and made to understand her peril, labor was begun and terminated so speedily and so satisfactorily. If it was not will power, what was it that retarded labor?

And just here I would like to ask a question: Do quinia and ergot promote uterine contractions in labor? or are they (the uterine contractions) the natural results of the completion of uterine gestation? No doubt many will think this a very foolish question; but having administered both drugs a great many times with apparently satisfactory results, I have at other times administered them without any more effect in that direction than if I had given so much water or flour, as they did in this case. Sometimes I am inclined to think there is not as much potency in them as they are given credit for.

J. CHEWNING, M. D.

Renault, Ills., April 18, 1884.

Ocean Grove and Asbury Park.

EDS. MED. AND SURG. REPORTER:—

With your permission I would like to call the attention of the profession to the advantages of Ocean Grove and Asbury Park. As a health resort, winter and summer, Asbury Park is a city of country homes by the sea, in the midst of a forest of pine and oak. Its long avenues, beautiful lakes, well laid out public squares; its business streets; its churches of every denomination; its schools; its sources of entertainment, where art and science join hands to please—all that the most fastidious could desire in the way of social life, is at command. In summer, undisturbed by rowdies or mosquitoes, the cool sea breezes make glad the heart; in winter, the climate, moderated by the same breeze, tempered by the waters of the Gulf Stream, and protected by the hills and forests in the rear, and a dry sandy country, leaves nothing to be desired, except it be the special security and Christian privileges of Ocean Grove, separated by a small lake from the Park here. In the Grove, strange to say, time seems a perpetual Sabbath, while the

Sabbath itself is like a long-continued psalm; scarce a sound, save the melody of praise and thanksgiving. The people live together in fellowship, and every man's neighbor is his brother. So carefully is it guarded, that even the latch-string is left hanging out at night in many of the sleeping homes. Here, too, the pines make fragrant the air; here flows the fountain from the artesian well, supplying the city with pure water. Its system of sewerage, said to be unequalled by any city along the coast, casts its refuse four hundred feet out into the sea, beyond low water mark.

The grand auditorium affords opportunity for daily varied exercises, re-unions and representations, and almost all Christian societies avail themselves of the peculiar advantages of the Grove. Representative men and women of the nation here may be seen, heard, and studied. It is indeed the place *par excellence* for literary men and worn-out brain workers to recuperate. The bathing is unsurpassed in Grove and Park, while the walks and drives leave nothing to be desired. The accommodations offered for guests, sick or well, are ample, with terms to suit all purses. Prominent among these as winter homes, is the Sheldon House, open summer and winter—spacious and well-appointed, especially adapted to meet the wants of the invalid, steam heat, gas, hot salt water baths, sources of amusement for indoor days—I might say, "perfect in all its parts"—central in the grove and convenient to the park, facing the beautiful Wesley Lake, and fronting the beach. Also, especially to be noted is the Atlantic House, wanting nothing to make comfortable its guests. Especially attractive in its management—so say my patients. While in summer, the elegance and luxury of hotels and homes fully meet every possible expectation.

My patients, visiting the Grove or Park, when troubled with either catarrhal or certain forms of lung troubles, as well as many disordered conditions, usually report marked improvement after a sojourn in the Grove. A visit in midsummer or midwinter would amply repay time and trouble of even a medical man. D. M. BARR, M. D.

1902 Spring Garden, Philadelphia.

Treatment Wanted for a Case of Dipsomania.

EDS. MED. AND SURG. REPORTER:—

I should be very thankful for suggestions from yourself and as many of your readers as may be pleased to give their experience, for the treatment of a case of dipsomania in an individual about 40 years of age. It is paroxysmal; a period of from two weeks to one month intervening between the attacks. He is a man of considerable intelligence; kindly disposed in his family; not quarrelsome or noisy when drinking, but when he gets as full as is compatible with locomotion, goes straight home, and to bed, where he remains until the influence of the liquor begins to pass off, when he returns to the saloon, and the process is repeated. He remains drunk from one to three weeks, during which time he is very careless of his personal appearance; but as soon as he begins "sobering off," puts on clean linen, dons a good suit, polishes his shoes, and is very painstaking about his toilet. He is also very confident that he will never drink again. My treatment has always

been confined to the attack, and consisted principally of sedatives (chloral, pot. brom., etc.) but I would like to try some plan of treatment in the intervals.

There are the usual premonitions of an attack, recognized by each member of his family.

Metamora, Ind., April 9, 1884.

Conception without Intromission.

EDS. MED. AND SURG. REPORTER:—

An article in the MEDICAL AND SURGICAL REPORTER of April 12th, entitled "A Case of Conception without Intromission," reminds me of a somewhat similar case that came under my own observation in 1870. I was called to see a young lady, nineteen years of age, who was supposed to have an ovarian tumor. I found her lying upon a sofa, and placing my hand upon her abdomen, proceeded to make the usual inquiries. In a few moments I felt the movements of a vigorous child. The patient asked: "Doctor, what is that? I have felt it for some time, and it grows stronger." I replied, "If you were a married woman I should unhesitatingly say it was a child." She said, "That is absolutely impossible." Upon further examination, I found an unruptured hymen completely closing the vagina, except an opening at its lower border not larger than a very small crow quill. I asked to see the "young man" in the case. He assured me he had never had connection with her, a statement I could very well believe; but he had been allowed to place his penis against the vulva, and emission had taken place while the organ was there. One month after, I delivered her of a healthy child. There could be no mistake about this—conception *had* taken place without intromission.

Newark, N. J.

WM. A. SMITH, M. D.

A New Treatment for Tape-worm.

EDS. MED. AND SURG. REPORTER:—

I have had within the last three years several cases of tape-worm to treat, and finding such strong objection to the large draught of medicines in ordinary use, I prescribed the following:

R. Chloroform.

Ex. male fern,

āā f. ʒj.

Emul ol. ricini (50 per cent.), f. ʒij.

M. Sig.—All to be taken at once after twenty-four hours' fast.

In every case the medicine was well borne, and the worm expelled entire. In two cases I omitted the male fern, and the result was the same as when the latter drug was in combination.

My object in reporting this treatment is to induce others of the profession to try the chloroform and report results.

I claim for this agent a specific and rational action as an adjuvant in the expulsion of the worm. It anesthetizes or suspends vitality, and any active purge during anesthesia of the tania is all that is requisite to expel it.

I earnestly ask those who have cases to try the chloroform, or chloroform and male fern, as above prescribed, and report results.

Puducuh, Ky.

J. G. BROOKS, M. D.

NEWS AND MISCELLANY.

Report of the Elk County Medical Society.

(Specially reported by Dr. SPENCER M. FREE.)

Fifth regular meeting for 1883-4.

After the usual exercises common to all societies, the essayist, Dr. Straitt, discussed the subject of "Medical Ethics." As this subject has been made a special order for our next meeting, no further mention of it will be made here.

There were two items of interest introduced under miscellaneous business, as well to the profession at large, as to our society. The first was a resolution instructing our delegates to the State Society to present to that body a request that a memorial be presented to Congress praying the publication of another edition of the *Medical and Surgical History of the War of the Rebellion*, and that its distribution be so arranged that physicians will be able to secure it. The majority of the society favored a gratuitous distribution; others that it be sold to the profession at the mere cost of publication.

The second matter of general interest, probably not beyond the limits of this State, was the appeal in behalf of Dr. Forbes, of Philadelphia, who incurred such loss, professionally and financially, in the lawsuit familiar to all the profession. Dr. Free proposed to the Society a series of resolutions, embracing, first, a contribution from our Society to our unfortunate brother; second, a censure upon the Jefferson Medical College for its indifference in the matter and its dishonorable treatment of Dr. Forbes; third, a request to all the county societies of the State to join us in the first two parts of the resolutions.

After an animated discussion, the motion for adoption of the resolutions was lost by a majority of one. A motion was then unanimously carried to send the contribution, accompanied only by the sympathies of the Society.

A rather unique case was presented to the society by Dr. Waid. A female, healthy, middle-aged, and married, has an attack of stomatitis at each menstrual period. Treatment is of no value. It recovers rapidly of itself when menstruation ceases.

Dr. Williams reported a case of severe pain along the course of the tibia. Has been of four months' duration. At the menstrual periods she is perfectly free from pain at this point, but it recurs on cessation of the menses. Curative treatment has been of little value. It is relieved temporarily by anodynes.

The subject of diabetes mellitus in children was discussed. It is the opinion of the majority, and, I should add, their experience also, that it is a very rare disease in childhood. One member in a practice of nearly twenty years had not met with a case. This corroborates the statements of our standard text-books on the subject.

No more cases of particular interest to the profession at large were presented.

Dr. Koch's Method of Examining Excreta.

The *Indian Medical Gazette* reports that on January 16, 1884, Dr. Koch, accompanied by Dr. Fischer and Dr. Gaffky, attended the *conversazione*

of the Calcutta Medical Society, and Dr. Fischer gave a demonstration of the methods employed by the German Cholera Commission. The culture-material used consisted of gelatine, meat-juice, and peptone. Water was examined by shaking a small quantity up with some of this prepared gelatine liquefied by heat; the mixture was then poured on to a sterilized glass plate and covered from the air. Separate spots appeared on the glass plate, due to the growth of micro-organisms; each spot was a separate colony, the germs having been distributed throughout the gelatine by the shaking. To the naked eye these spots or colonies differed among themselves. The unfiltered water of the Hooghly, and the filtered water supplied in the hydrants, produced results by this method differing very widely in degree; the hundredth part of a drop of water from the Hooghly produced a greater variety and number of colonies than ten drops of the hydrant water. In examining excreta, a small quantity was added to the liquefied gelatine in a tube, shaken, and poured out on a plate. Many different colonies grew and could be examined by the microscope, or used for inoculating fresh tubes so as to obtain pure cultivations. The stools of cholera, dysentery, diarrhœa, had thus been examined. One particular bacillus had been found regularly in the wall of the intestines and in their contents, in cases of cholera, but not in any one of the numerous other diseases examined. This bacillus, when growing in a colony on gelatine, was, of a white color in mass, and caused liquefaction of the gelatine.

Pennsylvania State Medical Society.

The thirty-fifth annual meeting of the Medical Society of the State of Pennsylvania will be held in the annex to the Union League (Broad and Sansom streets), Philadelphia, May 14, 15, and 16. The sessions will last from 10 a. m. to 5 p. m., with intermission from 1 to 2 p. m. A large number of very interesting addresses are promised, and the social entertainments are of such a nature as to insure a very pleasant meeting.

Location and rates of hotels near the place of meeting:

Saint George Hotel, Broad and Walnut streets, \$3.00 per day.

Aldine Hotel, Chestnut street, above 19th street, \$3.50 to \$4.50 per day.

Continental Hotel, S. E. cor. Chestnut and 9th streets, \$2.50 to \$4.00 per day.

Lafayette Hotel, Broad street, below Chestnut street, \$3.00 and upward per day.

The Bellevue, N. W. cor. Broad and Walnut streets, \$3.50 per day.

Girard House, N. E. cor. Chestnut and 9th streets, \$3.50 per day.

Colonnade Hotel, S. W. cor. Chestnut and 15th streets, \$3.50 per day.

West End Hotel, Chestnut street, above 15th street, \$2.50; rooms without board, \$1.00 per day.

Bingham House, S. E. cor. 11th and Market streets, \$2.50 per day.

Smedley House, Filbert street, below 13th street, \$1.50 to \$2.00 per day.

Great Western Hotel, Market street, above 13th street, \$2.00 per day.

[N. B.—Members and delegates should mention their connection with the Society when applying for accommodation, as some of the prices mentioned above are special rates given to the Committee of Arrangements.]

Italy at the International Health Exhibition.

The *Opinione*, in mentioning that His Majesty the King of Italy lately received Mr. Ernest Hart, of London, a member of the Executive Council of the International Health Exposition of London, and Mr. H. E. Acton, in 'special audience, adds: "The King received with interest particulars of the programme of the Exhibition, and entered at length into the details of the part which it was desired that Italy might take. His majesty referred to the measures in progress for accentuating the sanitary movement in Rome, the Campagna, Naples, Milan, and other parts of Italy; and desired that it might be publicly known that he felt a lively interest in the Exhibition, and a desire that Italy should be adequately represented." We learn by private letters that the Minister of the Interior has communicated to Mr. Hart a copy of a circular letter which he has addressed to the provincial prefects of Italy, desiring their active aid in the matter, and that the Minister of Commerce has addressed a like official request to the local chambers. The city of Rome has named a special commission to prepare for exhibition a series of models and plans of archaeological as well as of modern interest, illustrating the aqueducts, thermæ, columbaria, etc., and has voted a sum of money for the purpose. The food-products of Italy will be illustrated by private firms, and a large collection of the wines of North and South Italy will be shown.

Florida Medical Association.

JACKSONVILLE, FLA., April 3, 1884.

The Florida State Medical Association will hold its annual meeting in the city of Jacksonville, on Wednesday, June 4, 1884, at 12 m.

County medical societies are invited to send delegates, and all physicians who are graduates from regular schools of medicine are cordially invited to be present.

Essays are promised by the following physicians:

Dr. R. B. S. Hargis: "Malaria and the Relations of Micro-Organisms to Disease."

Dr. R. P. Daniel: "The Tongue in Disease, and its Diagnostic Value."

Dr. C. J. Kenworthy: "Phthisis Pulmonalis."

Essays expected from other prominent physicians.

T. M. Palmer, M. D., orator.

Efforts will be made by the Committee of Arrangements to obtain half-rate tickets on railroad and steamboat lines for delegates to the Association.

E. T. SABAL, M. D., President.

Attest: A. W. KNIGHT, M. D., Secretary.

What He Knew about Digestion.

In the *Brit. Med. Jour.*, we read that a candidate at a recent examination for a scholarship under the school board is reported to have made the following statement concerning the process of digestion: "The food passes through the liver,

and evaporates by means of little holes called capillaries." The examiner who published the answers suggests that this novel theory had its origin in the study of some cheap diagram of the digestive system. Knowledge of this kind is indeed a dangerous thing, and worse than conscious ignorance. There is a simple ignorance and there is a compound ignorance—that is, there are people who are ignorant and know that they are, and there are people who are ignorant and think they know. The latter only are a dangerous class.

Small-pox in India.

The epidemic of small-pox which has been prevalent in Madras since the beginning of the year, would seem to have assumed very serious proportions. About twelve hundred deaths from this cause occurred in the town of Madras during the first two months of the year, and telegraphic dispatches state that the epidemic is still raging in the town. In spite of some quarantine precautions, chiefly the careful inspection of all persons entering Bangalore from Madras by train, and the watching of the main road between the two towns, small-pox has appeared at Bangalore. The latter town is an important military centre. Vaccination with calf-lymph is being extensively performed.

The Judge and the Consumptive.

"Stop that coughing over there!" cried a New York judge. "Such coughing disturbs the business of the court."

There was a short, painful silence, writes Eli Perkins, during which a pale, consumptive man struggled with himself, then coughed again, and continued it for several minutes.

"I'm bound to stop that coughing!" exclaimed the judge. "I'll fine you \$10. I think that will stop it."

"Jedge," said the cadaverous man, "I'd be willin' to pay \$20 to have that cough stopped. If you can stop it for \$10, you'd better get down off that bench and go to practicing medicine. There's money in it, jedge—money in it!"

Cremation in Italy.

The Minister of the Interior in Italy, after consultation with the Sanitary Council, has decided on the following rules with respect to the cremation of human bodies and the societies formed for that purpose:

1. The societies will be considered responsible corporations as soon as their economical conditions give sufficient guarantee for their permanent existence.

2. The cremation of human bodies will be subordinate to a permit from the political authorities, to obtain which the consent of the family of the deceased must be produced.

The Adulteration of Drugs in Massachusetts.

A remonstrance has been laid before the Massachusetts Legislature against any change in the present law relating to the adulteration of drugs. It is signed by Dr Alfred Hosmer, the president of the Massachusetts Medical Society, Dr. George C.

Shattuck, Dr. George H. Lyman, Dr. Benjamin E. Coting, and Dr. Henry W. Williams. The document urges that the United States Pharmacopœia should be the only standard of the strength and purity of drugs.

The Surgical Pantograph.

At a meeting of the French Association for the Advancement of Science, held at Rouen, M. Mallez presented an instrument of precision called a surgical pantograph, for measuring the dimensions of the enlarged prostate, and for demonstrating by the aid of graphic tracings the influence of treatment on the diseased organ.

Items.

—There are said to be twelve medical journals published in Japan.

—Dr. Kassowitz (*Central für Chir.*, January 26, 1884,) recommends phosphorus in cod-liver oil for rickets.

—Among the candidates for the *externat* of the Paris hospitals, Mlle. Mathieu, a negress, has competed with success.

—The isolation of consumptive soldiers, according to the "*Progrès Médical*," has been decreed in the military department of Prussia.

—The Free Hospital for Women of Boston, Mass., has recently received a gift of \$35,000 from the wife of Lieutenant-Governor Oliver Ames.

—The Boston Board of Health has appointed Mr. George W. Forrestall superintendent of health, Dr. John H. McCullum city physician, and Dr. Arthur C. Griffin port physician.

—The bill prohibiting the manufacture and sale of oleomargarine within the limits of the State of New York has passed the Senate, with an amendment reducing the penalty to between \$100 and \$500.

—Mr. Erastus Brooks, of Richmond county, Dr. J. A. Delavan, of Albany county, and Mr. George W. Cooke, of Ulster county, have been appointed members of the New York State Board of Health.

—A newspaper report from Camden, N. J., states that scarlet fever has been spread in Gloucester City by children having eaten ice which had been used by an undertaker on the body of a person dead of the disease.

—"Rye and Rock" confectionery, as was confessed by the makers on the occasion of a hearing before Health Commissioner Raymond, of Brooklyn, recently, is flavored with an extract, and mention was made of fusel oil being used in the manufacture.

—The lay nurses of the Paris hospitals do not seem to have given the satisfaction that was expected of them at the time they were substituted for the Sisters of Charity, judging from a report to the effect that a well-known surgeon of *La Charité* has written a letter denouncing the exclusion of the latter.

—The medical society of the county of Richmond (N. Y.) is reported to have taken the step of passing a resolution prohibiting any member

from rendering professional services to any person against whom another member has a bill for like services which he is unable to collect.

—"It's no use to feel av me wrihst, doctor," said Pat, when the physician began taking his pulse; "the pain is not there, sure, it's in me hid, entirely."

—M. Martineau has observed that in a monkey inoculated with syphilis, who has already presented secondary symptoms and a syphilitic ulcer of the palate, a third manifestation has appeared—syphilitic epilepsy.

—Prof. Da Costa teaches that Addison's disease is not any indefinite affection of the supra-renal capsules, but a certain pathological process in them—a low grade of inflammation leading to cheesy degeneration. He, personally, has had best results from treatment with arsenic and cod-liver oil.

—Dr. Angus Smith, F. R. S., reports to the Local Government Board, as one of the inspectors under the Rivers Pollution Prevention Act, that in all natural waters sugar ferments and hydrogen gas is given off, the proportion varying with the organic impurity of the water. The proportion of hydrogen evolved will prove a quantitative test of the virulence of the microbes present in the waters.

—The inspection of meat in New York is in a fair way to be made more thorough than it has been heretofore, bills having been introduced into both houses of the legislature providing for the appointment of five inspectors of meat by the board of health, and making it a punishable offense to offer for sale any meat that has not been inspected by them, the inspection to be repeated every second day until the meat is sold.

OBITUARY NOTICE.

PLINY A. JEWETT, M. D.

Dr. Pliny Adams Jewett, one of the leading physicians of New Haven, Conn., died in Providence, R. I., April 10, of pneumonia. He was called as an expert both in the Hayden and the Malley trial, and he was in Providence as a witness in a murder case when seized with the disease which caused his death. Dr. Jewett was born in Hampton, Washington county, New York, in 1816. He received his education in Trinity College, Hartford, Conn., and afterward took a medical course at Yale. He was graduated from the latter institution in 1839, and went to Paris to further perfect his studies. He afterward settled in New Haven, and with the exception of two years' residence in Aiken, S. C., he has since lived there. In 1847, he married a daughter of Leicester Carrington, a prominent citizen of Bristol, Conn. For 40 years Dr. Jewett has been attending surgeon at the New Haven Hospital, and he was for 12 years Professor of Obstetrics in the medical department of Yale. During the war he was surgeon of volunteers, and was afterward promoted to a colonelcy for meritorious services. Dr. Jewett organized Knight's United States Army General Hospital at New Haven, and he had charge of it from 1862 to 1865. He was a member of the Connecti-

cut Medical Society for 37 years, serving as its president in 1876. He was also an honorary member of the New York Medical Society. Two sons and a daughter survive him.

MARRIAGES.

ATKINSON—SMITH.—In this city, at their home, April 4, 1884, by the Rev. W. W. Barr, D. D., W. B. Atkinson, M. D., and S. Jennie Smith. No cards.

BARNES—DRUMMOND.—At the residence of the bride's parents, 258 Grand street, New York, Thursday evening, April 10, 1884, by the Rev. A. D. Vail, of St. James M. E. church, Dr. Allen D. Barnes, of Boston, Mass., and Alice, youngest daughter of William L., and granddaughter of the late Sir M. J. Drummond, of this city.

CHAFFIN—HAYNES.—At the residence of Colonel S. C. Rogers (Bellevue), near White's Station, Tenn., April 3, 1884, Dr. N. W. Chaffin and Miss Katie Belle Haynes, of Gainesville, Texas.

ELMORE—URBAN.—At the residence of the bride's mother, March 31, 1884, J. P. Elmore, M. D., of St. John Baptist Parish, La., and Miss Julie E. Urban.

FAULKNER—HAGUE.—At the residence of the bride, in Allegheny City, Pa., April 9, 1884, Dr. R. B. Faulkner and Miss Emma Hague, both of Allegheny City, Pa.

FROST—RAINS.—In Nashville, Tenn., April 7, 1884, Dr. Sterling Brown Frost and Mrs. Rebecca B. Rains, widow of the late William Rains.

GREENE—HEDDEN.—At the residence of the bride's parents, on Dewey Heights, near New Albany, Ind., April 10, 1884, Dr. Frank E. Greene and Miss Annie W. Hedden, daughter of David Hedden.

JOHNSON—MATIER.—In Wilmington, Vt., April 2, 1884, by the Rev. A. W. Goodnow, Dr. Albert M. Johnson and Mary H. Matier, both of Wilmington.

LYLE—ALEXANDER.—In Belleville, Pa., April 9, 1884, by the Rev. T. R. Alexander, Dr. John W. Lyle, of Washington county, Pa., and Ada E. Alexander.

RICHARDSON—BOULTENHOUSE.—In this city, April 8, 1884, at No. 1921 Poplar street, by the Rev. Chauncey Giles, M. E. Richardson, M. D., and Miss Minnie Boultenhouse, both of this city.

SEGUIN—CROSS.—In New York, April 15, 1884, by the Rev. Alexander Mackay Smith, Dr. E. C. Seguin and Helen Cross.

DEATHS.

ILLIG.—At his late residence, Carey, Wyandot county, Ohio, Friday evening, February 8, 1884, Dr. Gus. F. Illig, aged forty-five years, two months, and twenty-six days.

BARBOUR.—Near Pilcher's Point, Carroll Parish, La., April 7, 1884, Dr. Philip N. Barbour, son of Mrs. Elizabeth G. Stewart, of Louisville.

ECKFELDT.—In Washington, D. C., April 10, 1884, Dr. Frederick Eckfeldt, aged forty-four years.

EDSON.—At Manchester, Vt., April 14, 1884, Dr. Ezra Edson, late of White Plains, N. Y., in the seventy-sixth year of his age.

GREGORY.—At Blenheim, Hanover county, Va., April 8, 1884, Dr. Thomas L. Gregory, in the fifty-fourth year of his age.

HASTINGS.—In New York, Tuesday, April 15, 1884, Dr. Dan. Hyde Hastings, M. D., in the seventy-third year of his age.

McMURRAY.—In this city, April 7, 1884, Andrew Stewart McMurray, M. D., in the seventy-fourth year of his age.

PATTISON.—At Brooklyn, N. Y., Easter Sunday, April 13, 1884, Matthew Moncrieff Pattison, M. D., son of the late John Pattison, of London, England, and Maria Hoffman, of Goshen, N. Y., aged thirty-eight years.

RAMSEY.—In Knoxville, Tenn., April 11, 1884, Dr. J. G. M. Ramsey, a historian of Tennessee, aged eighty-seven years.

SHEPPARD.—At Colorado Springs, Monday morning, April 14, 1884, Dr. Frederick C. Sheppard, in the twenty-eighth year of his age.

SMITH.—In St. Louis April 2, 1884, Dr. H. R. Smith, a native of Bridgewater, England.

ORIGINAL DEPARTMENT.

LECTURE.

SYNOPSIS OF A LECTURE ON THE TREATMENT OF CHANCROID AND SYPHILIS.*

BY JOHN ASHHURST, JR., M. D.,
Of Philadelphia.

In introducing this subject, Dr. Ashhurst said that, as he believed that chancroid and syphilis had no connection with each other, except that they were commonly acquired under similar circumstances, it might seem strange that he should join them together in speaking of their treatment. The explanation, he said, was that two years ago, when he had had the honor to address the Society on the diagnosis of chancroid and syphilis, the Society requested that on some future occasion he would speak on the treatment of these two affections. In obedience to that request he had the honor to appear to-night.

THE TREATMENT OF CHANCROID AND SYPHILIS.

If any constitutional treatment is demanded in chancroid, it is such as is indicated by the general condition of the patient. Chancroid requires local treatment, but as syphilis is a constitutional affection, its treatment is constitutional or general. Local treatment is required for certain manifestations of syphilis, but the treatment, *par excellence*, is constitutional.

Speaking first of the treatment of chancroid, we may recognize three plans which have been adopted.

First, That form of treatment which aims to abolish the whole thing at once, that is, by ex-

cision. There are certain maladies in which, by this plan, we can get rid of the disease entirely, as in the case of certain tumors. So a local disease, which has begun in one or more spots, should theoretically be removable by cutting away the diseased tissue. This plan has, however, been tried and found wanting. The great objection to it is that the wound almost inevitably becomes inoculated by the chancroidal matter, and that the resulting sore is larger than the first one was, thus rendering the ultimate condition of the patient worse instead of better.

The second form of treatment, and that which I advocate, is one which aims not to remove the disease at once, but to favorably modify its future progress. This is the treatment by cauterization. By destroying the surface of the chancroidal ulcer, we remove its virulent qualities, and leave a healthy granulating sore. The caustic application removes the tendency to spread, and converts the ulcer into a healthy granulating surface. In speaking of this tendency to spread, I refer to one of the most prominent features of chancroid, its auto-inoculability, in which it differs from the initial lesion of syphilis. Chancroid is auto-inoculable indefinitely, and I believe that cauterization very much diminishes, if it does not destroy, this property. Although the pus from the chancroid is still contagious, it seems to lose, after cauterization, to a great extent, that quality which causes it to spread to other parts on the same person. In the choice of a caustic, my preference is for fuming nitric acid, applied by means of a piece of soft wood, such as the end of a match-stick. Another plan is to apply the acid by means of a glass brush, but I do not think this as desirable.

* Delivered before the Philadelphia County Medical Society, January 9, 1884.

Every cranny should be cauterized. Any part that escapes retains its quality of furnishing auto-inoculable pus, and the whole surface may return to its former condition; therefore, cauterization must be thorough if it is practiced at all. When the slough, produced by the caustic, separates; the surface soon granulates and heals; but the pus is contagious to the last. If the fear of pain deter the patient from submitting to cauterization, general anæsthesia may be properly employed, or the surgeon may first make an application of carbolic acid, which produces local anæsthesia, and apply the nitric acid afterwards. It may be necessary to repeat the operation.

There are other modes of effecting cauterization; one is the use of the carbo-sulphuric paste, recommended by French surgeons. This forms a crust, which I think is a disadvantage, as concealing the parts beneath. The solution of acid nitrate of mercury may be used, but if applied over an extensive surface it may cause salivation. It is not as well adapted to the purpose as nitric acid. The actual cautery also has strong advocates; it may be employed either with the simple hot iron, or with the Paquelin's or the galvanic cautery. These modes of cauterization are effective in cases of serpiginous chancreoid—in the latter I think the hot iron the best application that can be made. The material used by many practitioners a few years ago, the nitrate of silver, is inefficient, and, in my judgment, has nothing to recommend it. Then for the after-dressing, after cauterization has been employed, we can use plain water, or lime-water, or black-wash, or a solution of salicylic acid, or what is known as the "nitric acid wash" (nitric acid f. 3 j; water Oj), which is much used as a dressing in New York. When the chancreoid is on a mucous surface, as in the female organs, or in any situation in which it is kept moist, a simple dry dressing of absorbent cotton or dry lint may be used; but where the chancreoid is exposed, dry dressings are apt to become adherent, and wet applications are better. The dressing above all others which I think deserves attention, is iodoform. It is a comparatively recent remedy in these cases, and I think that it is the best application that can be made after thorough cauterization has been effected. It can be used in various ways, by simply dusting the finely-powdered drug over the surface, or as a wet dressing in the form of an alcoholic solution with glycerine, viz: Iodoform 3 ss; alcohol f. 3 ij; glycerine f. 3 vj. Or it may be used in the form of an ointment, 15–30 grains to the ounce, or as an ethereal solution which evaporates, leaving a thin

film of iodoform over the surface. An old remedy, which formerly had great reputation in these cases, was aromatic wine; but I do not think it is as efficient as iodoform. Another remedy, which is quite a novel one, is resorcin, an article of the phenol series. Great advantage has been claimed for it. Pyrogalllic acid has also been used, as has the subnitrate of bismuth and various other dry powders. In the female, dressings, of course, must be applied with the aid of the speculum.

In chancreoids at the meatus, I commonly use a solution of nitrate of silver (30 grs. to f. 3 j.), since the contraction after the use of nitric acid might be objectionable in this situation. At the frænum some special precautions may be required. Deep cauterization here may be followed by bleeding, and it has been proposed to prevent this by the previous application of ligatures, tying the frænum above and below the seat of disease, or by employing the actual cautery. For chancreoids beneath the prepuce, when this can be retracted, the best plan is to cauterize the sores and dress them in the ordinary way, either replacing the prepuce afterwards, or allowing it to stay retracted, as may be thought the most convenient. If, however, the prepuce cannot be retracted, then the surgeon may inject a strong solution of nitrate of silver, or, which I prefer when it can be done, may pack the space between the prepuce and the glans penis with lint saturated with a solution of nitrate of silver (gr. xx. to f. 3 i.). Whenever it is necessary to circumcise the patient, of course the wound should be cauterized, as it will otherwise become inoculated and itself converted into a large chancreoid. As for urethral chancreoids, which are very rare, cauterization cannot be employed, as increasing the risk of stricture; absorbent cotton may be used as a dressing, taking care to have a thread attached by which the dressing may be withdrawn. About the rectum and anus, chancreoids may be treated by cauterization, with the subsequent use of emollient enemata and opium suppositories. For the phagedænic chancreoid, constitutional treatment is desirable, as in all other cases of phagedæna. Opium—one grain at night and one grain in the morning—is, I think, more beneficial than any other single remedy. In some cases it may be of advantage to remove the surface of a phagedænic or serpiginous chancreoid by scraping with a scoop, and then using as a caustic, bromine, permanganate of potassium, or caustic potassa; but I think that the hot iron is the best local remedy in these cases. Syphilization has been used for chancreoid, but it is of no value.

In regard to the principal complication of chancre, the bubo, it may be of two kinds, the simple or inflammatory bubo, which is nothing but an adenitis, or the true chancroidal or virulent bubo. I believe it to be impossible when a bubo first makes its appearance, for the surgeon to say of which variety it is. Of late years I have seen many more examples of the simple than of the virulent bubo. Whether or not this is because the disease, like syphilis, is gradually becoming a milder affection than it was formerly, I cannot say.

In regard to the treatment of bubo, the surgeon should enforce rest in bed, if possible. Then counter-irritation should be employed very thoroughly. The best way is that suggested by Mr. Furneaux Jordan, of Birmingham, by applying the counter-irritant to the "next vascular area." The theory is that by irritating an adjacent part, the blood is caused to flow away from that originally affected. Counter-irritation is best effected by applying the tincture of iodine in the form of a broad horse-shoe around the inflamed gland, every day or every other day, so as to keep the part on the verge of vesication. The skin should, if possible, not be broken, but if it is so, some soothing ointment must be applied, and the use of iodine suspended for a few days. Over the bubo itself, the dressing which I have found most satisfactory consists of equal parts of belladonna and mercurial ointments; it is a simple resolvent and anodyne application, and is agreeable to the patient. I have also used an ointment of iodoform over the part, but do not think it as efficient as the belladonna and mercury; nor do I think the application of blisters as satisfactory as the use of iodine. Pressure is another remedy which may be properly employed when the bubo is not painful, but which is ill-adapted to the acute inflammatory stage. If it is to be employed, pressure may be effected by applying a shot-bag over the bubo while the patient is in bed; or by fastening a soft sponge over the part with a spica bandage applied with the thigh flexed on the trunk. If the bubo suppurates, of course it should be opened. Various plans have been suggested, but I do not think there is anything as efficient as a moderately free incision; and the direction in which this is made is a matter of considerable importance. I find that practitioners generally open buboes in the line of Poupart's ligament, but I think that an incision in the long axis of the patient's body is the best, supplemented, if necessary, by small transverse incisions on one or both sides. If the flaps of the

wound are kept apart, so as to allow the pus to flow out readily, the process of healing is much more rapid. Multiple punctures have been employed in opening buboes, and the introduction of a seton has also been suggested; in case phagedæna attacks the bubo, the use of the continuous hot bath has been proposed. My experience is here, too, in favor of the use of opium, locally and internally, and, if cauterization is necessary, the application of the hot iron. I think that there is an advantage, as regards the bubo, in a thorough cauterization of the original chancreoid at the beginning. Bumstead and Taylor recommended that cauterization should be employed if it can be done in the first ten days; but if it is desirable in the first ten days, it seems to me to be proper at any period. These gentlemen believe that by early cauterization the patient will escape virulent bubo, and that even if an inflammatory bubo exists, its course will be favorably modified. I am aware that a directly contrary opinion is held by some surgeons, who believe that the risk of bubo is increased by cauterization; but, as far as my own experience goes, it confirms the teaching of Bumstead and Taylor.

If the surgeon is satisfied that he is dealing with a chancroidal or virulent bubo, simple incision is not sufficient. Here suppuration occurs first in the periglandular areolar tissue, and it is of great advantage to enucleate the infiltrated glands before they become disintegrated and inoculate the surrounding tissues with chancroidal matter. If the case is not seen until the whole wound has become inoculated, then I would slit up all sinuses, remove the thinned overhanging skin, and cauterize the whole surface with nitric acid, the patient being under the influence of ether.

The third plan of treatment, which is the fashionable treatment just now, is the use of simple dressings, such as I have advised for the after-treatment, without employing caustics. There is no doubt that healing will, in most of the mild, superficial chancroids met with at the present day, ultimately take place without cauterization; but I think the cure will be more certain, more rapid, and more likely to be free from complication, if the chancreoid be cauterized in the way that I have recommended.

Treatment of Syphilis.—Syphilis is a constitutional affection, and demands constitutional treatment. The principal remedies are mercury and iodide of potassium. These have been given for many years, and yet it has never been satisfactorily determined in what way they produce their

effects. Probably it is safest to say that they act by eliminating the syphilitic poison and producing absorption of the gummatous and inflammatory deposits. No doubt, according to modern theories, they might be supposed to act by destroying syphilitic germs, but that suggestion opens questions in transcendental pathology into which this is not the time to enter.

For the convenience of considering the treatment of syphilis, we may divide its course into the primary, secondary, and tertiary stages.

The lesions of the primary stage are the initial lesion (or chancre) and the bubo which accompanies it. Now, in regard to the treatment of primary syphilis, I believe that the surgeon will do well to put his patient under mercurial treatment, provided that he is sure of his diagnosis. This view is opposed, however, by some authorities for whom I have great respect. My practice is to give mercury; and the best form in which it can be given, in the primary stage, is the green iodide or protiodide. I have been in the habit of prescribing this preparation in pills with opium alone, or made up with a confection of opium as an excipient: it has the advantage that it can be used a long while without causing salivation, and it is, moreover, efficient. I think that this is the safest mode of treating syphilis in the primary stage, but no patient should be placed on a mercurial course unless the surgeon is well satisfied that syphilis is actually present.

In regard to the local treatment of primary syphilis, the principal point is cleanliness; but local treatment is not of much value. Iodoform may be used as a dressing for the chancre, as it may for the ulcerative lesions met with in the later stages of syphilis. Cauterization is of no service. I do not believe that secondary symptoms were ever prevented by cauterizing a chancre.

There is another form of treatment which has some evidence in its favor, and that is the excision of the chancre.

Until within a few years the view of surgeons was that a chancre should not be excised except under special circumstances, as when occurring on an elongated prepuce; but within recent years the excision treatment has been revived, particularly in Germany, and in this country it has been advocated by Dr. White and others. To those who, like myself, take the view that syphilis is a constitutional disease from the beginning, and that the initial lesion, chancre, is but its first manifestation, of course the excision treatment seems somewhat unphilosophical. I have no

personal experience in this form of treatment, but the weight of evidence, from what I have been able to read concerning it, seems to me to be against it. This, moreover, appears to be the prevailing view among the leading specialists in venereal affections in New York.

As regards the bubo of syphilis, no special treatment is required, though I have sometimes thought that I have derived advantage from the application of iodoform ointment.

In the treatment of the secondary stage of syphilis, of course mercury is the great remedy. Iodide of potassium is used by some surgeons in the primary stage, but for secondary syphilis all are agreed to use mercury. It should be used gradually, to prevent salivation on the one hand and intestinal irritation on the other. I think the best way in which it can be used is by inunction. I recommend the patient to rub ordinary mercurial ointment, or an ointment of the oleate of mercury, into the inner side of the thighs, using fifteen grains each morning and night, half a drachm altogether in the course of the day. If this seem too much, the remedy can be suspended for awhile, and then used in diminished doses. Another good plan is to apply the ointment to the soles of the feet, wearing woolen stockings; the place of application should be frequently changed, so as to avoid the occurrence of mercurial eczema. Before each application, too, the skin should be thoroughly washed and dried. In cases of infantile syphilis, Brodie's plan of putting the mercurial ointment on the belly-band is a good one.

If a patient objects to inunction, the mercury must be given by the mouth. The old-fashioned blue-pill is one of the most efficient preparations, if it is given cautiously; or the iodide may be used, or the bichloride, which, however, I think less useful than the others. Mercurial fumigation is a good method of treatment in certain obstinate forms of cutaneous syphilis, but is too troublesome for ordinary employment. Another mode of administering mercury is by hypodermic injections, usually of from $\frac{1}{12}$ to $\frac{3}{8}$ gr. of the corrosive chloride, though almost any preparation of mercury may be used hypodermically. I do not think that this plan presents enough advantages to counteract its disadvantages, and believe that it should be reserved for exceptional cases.

For mucous patches, constitutional treatment must, of course, be continued; and as a local remedy the solution of acid nitrate of mercury may be applied, being then followed by some simple dressing, such as black-wash, and iodoform afterwards. Another plan, recommended by Conradi,

is to use a strong solution of nitrate of silver, and then to apply metallic zinc. For syphilitic sore-throat, gargles of chlorate of potassium may be employed, or cauterizations with the liq. hydrarg. pernitratiss; or dilute hydrochloric acid may be applied with an atomizer. For syphilitic iritis, I have been favorably impressed with Carmichael's mode of treatment, which consists in the administration of oil of turpentine in large doses. I have often used this with great advantage, but have on the other hand sometimes found it to fail, and have had to come back to mercury. The oil of turpentine is given in large doses (f. ʒj.) three times a day, in emulsion with gum and sugar, with a few drops of the tincture of opium to prevent strangury. The most important point in the treatment of iritis, however, is the local use of atropia. For alopecia, cantharidal washes may be recommended.

In the tertiary stage of syphilis, iodide of potassium is the chief remedy. Mercury is useful in the treatment of the dry eruptions and of interstitial orchitis, but not in the gummatous affections, where iodide of potassium is preferable. At the same time tonics must be given, as indeed in the secondary and primary stages also. An expectant plan of treatment has been suggested for syphilis, but it is not to be recommended, nor would I favor hygienic and tonic treatment by itself, though in connection with specific treatment it is of great value. A patient who leads a regular life, avoiding the use of tobacco and alcohol, and at the same time pursuing a proper course of treatment, has a better chance of recovery from syphilis than one who neglects hygienic measures.

In giving mercury for syphilis, there are two plans of proceeding: one in which small doses are given continuously for a long time, as particularly advised by Dr. Keyes, of New York; and the other, which seems to me more philosophical, in which the drug is given "*coup sur coup*," that is, in successive courses with intervening intervals. The doses should be moderate, and salivation should be avoided. The best way is to give mercury cautiously until the symptoms are relieved, or a few weeks longer, and then to suspend it altogether. Then, if there are any fresh symptoms, the administration may be renewed.

It has been proposed by Mr. Venning, as a test to determine when syphilis has been removed from the system, to examine the condition of the inguinal glands. If there is any induration remaining, the patient is still syphilitic.

Iodide of potassium may be used very freely in syphilis. Formerly, five-grain doses were ordi-

narily given, but from eight to ten grains is now considered a fair dose to begin with, and in some cases much larger quantities must be employed. I am convinced, however, that the drug is often given in excessive amounts in ordinary cases of syphilis. I do not recommend large doses unless the disease fails to respond to smaller ones, or unless the symptoms, as in some cases of cerebral syphilis, are immediately threatening to life. The iodide may be given simply in water, or with the compound syrup of sarsaparilla, or with fluid extract of gentian, viz.:

Pot. iod.,	gr. viii.-x.
Ext. gent. fl.,	℥xv.

With enough water to make a teaspoonful. Iodoform has been given internally, and homœopathic practitioners have employed gold, but neither appears to have any special value. Sarsaparilla used to be looked upon as an important remedy for syphilis, but I have never found that it was of any use whatever. A remedy strongly recommended by the late Dr. Sims was stillingia. Dr. Taylor speaks favorably of the erythroxylon coca. Hot baths are undoubtedly of use sometimes in syphilis. For hereditary syphilis, mercury and iodide of potassium, in doses suited to the age of the patient, and combined with tonics, and especially iron, are of use. If a syphilitic woman is pregnant, she should undergo a mercurial course, in hope of preventing infection of the fœtus.

COMMUNICATIONS.

THE LANCET VS. VERATRIA IN PNEUMONIA.

BY E. MICHENER, M. D.,
Of Toughkenamon, Pa.

I have often found that men, in their opinions and practices, are very much like *cranks*—I mean mechanical, not psychological cranks. All seem to have their *dead points*; and doctors are not an exception. While we can point out those dead points in *others*, we do not readily notice *our own*; we do not see ourselves as others see us. Hence, it is an act of kindness, indeed it becomes a *reciprocal duty* to point out and correct each other's weak points.

Apropos. (See Country Practitioner, March, 1881.) The editor, *E. P. Townsend, M. D.*, writes: "In view of the recent articles by *Dr. Hiram Corson*, in the *MEDICAL AND SURGICAL REPORTER*; also, one in the February number of this journal, by *Dr. Ezra Michener*; and a reprint in the present

number of one by Prof. S. D. Gross, upon the subject of blood-letting, each of whom refers to *pneumonia* as one of the diseases whose fatality has increased since blood-letting has gone out of fashion, I have thought it advisable to report the clinical notes of a case that occurred recently in my practice."

As Dr. Townsend was kind enough to indicate what he considered our *dead points* in the papers referred to, I would gladly have reciprocated the favor, but was physically unable at the time to do so, and the journal was soon after suspended. But I feel that the obligation still awaits an acknowledgment.

Note.—I can only and briefly notice this interesting case so far as it has relevancy to the "*Lost Art*" in similar cases.

Dr. Townsend says—on what authority I do not know—"That *they* bleed to reduce the power of the heart. (?) Then, why not reduce the power of the heart with *veratria*, and save the blood? What is the use of losing the blood, when the heart can be controlled just as well without it?" This, however, is a mere assumption of the points at issue. I demur, 1, That we do not bleed for this special purpose in pneumonia; and 2, His *ipse dixit* does not prove the assumption, that the object can be obtained just as well without it.

Again, "What kept up the engorgement of the lungs? The rapid action of the heart. And, evidently, the indication was to quiet the heart."

All this may have seemed conclusive to the author, and is expressed with an air of satisfaction. But, it may be asked, whether the congestion of the lungs did not *precede* the increased heart action? Whether the congestion did not still *persist* after the heart had been controlled by *veratria*? Whether a judicious bleeding would not have *relieved* alike both of the suffering organs?

No one, I suppose, will seriously deny that the heart was accelerated by a natural effort to *overcome* increased obstruction in the lungs. It is a *normal* action, where action is *adequate* to the purpose. We bled to lessen the obstruction—to relieve the lungs of a *burden*, which they are *unable* to carry. For a practical illustration, I would refer the reader to Dr. I. H. Stubbs' report of my own case (MEDICAL AND SURGICAL REPORTER, July 8, 1882).

Other matters aside; the *death-roll* of this disease seems to indicate a fearful era when *veratria* and *whisky* were substituted for *blood-letting*.

But we are told "*that the patient had ALL HIS BLOOD IN HIS VEINS—EXCEPT what he had lost through the lungs.*" (!!!) Yes; and, pray, how much was

that??? The doctor has not told us. But he has furnished data sufficient to *create a doubt* whether his patient was cured by *veratria*, or by the free and persistent *loss of blood*, kept up continuously, for *many days*. I can only give the data, leaving it for those who are more familiar with *veratria fluxions* to find the aggregate amount of blood that was lost or saved by the *economical procedure*. Thus:

January 11, 8 p. m. Sputa considerable, *rusty*, and *blood-streaked*.

January 12, 4 a. m. More free; containing *much more blood*.

January 12, 8 a. m. More profuse, and *more bloody*.

January 13. No report.

January 14, 8 a. m. Profuse.

January 15, 8 a. m. Sputa abundant and *sanguineous*.

January 16. Less profuse; *still bloody*.

January 22. Discharged.

If the patient possessed an abnormal quantity of blood, it could have been withdrawn with relief rather than prostration. If, on the contrary, agreeably to the *Bosses*, a man never has more than a normal quantity, it is worse than idle to say, "that his system was not called upon to manufacture thirty, or forty, ounces of blood to supply deficiencies."

If my clinical experience for sixty-eight years has taught me anything, it is this, that a judicious bleeding, on the first visit, would not have caused prostration, but would have reduced the disease to a *minimum* in duration and violence, and would have prevented, or greatly lessened, the *after-bleeding* from the lungs, and all other sources of exhaustion.

I have only noticed the *dead points* of the *crank*, which seemed to require a *balance-wheel* to carry them *safely over*.

PARTIAL OSSIFICATION OF THE UTERINE SURFACE OF THE PLACENTA.

BY W. H. DEARING, M. D.,
Of Malvern, Iowa.

Was called February 20, '83, to attend Mrs. S., age 21, in her first confinement. Fifteen hours after the pains first appeared she was delivered, per vias naturales, of a male child, whose weight was ten pounds. The first and second stages of labor were unaccompanied by accident. After waiting a proper length of time for the completion of the third stage without the desired result, I introduced my hand into the womb for the pur-

pose of ascertaining the cause of the non-delivery of the placenta. I admit I was somewhat mortified to find that I had a case of adhesion; but thinking it probably was of a simple form, and that a little time would bring around the desired result, I waited two hours without my expectations being realized. I then detached the placental mass slowly with the tips of my fingers, and finally brought it away. But upon examining the uterine surface of the placenta, I was greatly surprised to find it almost entirely ossified.

Dr. Dubois furnishes an instance of an abnormal adhesion of the placenta, in which the uterine surface was covered by an osseous or cretaceous substance; and Gooch reports that he found the placenta partially ossified three times in the same woman. Monro and Merriman also report several cases where they noticed ossification on the uterine surface of the placenta, in which the latter adhered a little more than usual. In a case detailed by Dr. Stoltz, the bond of union was evidently formed by a layer of coagulated blood, which had served to arrest a hemorrhage at the fourth month of gestation. Dubois accepts this view, and attributes these adhesions to patches of a whitish nature, of a greater or less degree of hardness, evidently of a fibrinous nature, and increasing in density with the age of the sanguinous effusion of which they are the only remains.

There was no history of hemorrhage or inflammation in the history of this case prior to confinement, after which she rapidly regained her former health, and soon assumed her household duties. No uterine trouble that has made itself known by an untoward symptom, has yet appeared. What the cause of the ossification and adhesion was in this case can only be theorized upon, and it remains for some future confinement to prove whether or no she will follow in the wake of Gooch's patient, and bring forth at each subsequent labor a placenta whose uterine surface is paved with stone.

HOSPITAL REPORTS.

CASES FROM BELLEVUE HOSPITAL, NEW YORK.

Reported by J. H. WOODWARD, M. D.

Acute Lobar Pneumonia.

John A., age 42, was admitted to Bellevue Hospital February 12, 1884. Patient stated that five days prior to admission to the ward he was seized with pains in all regions of his body, and that the pain in the region of his left nipple was particularly severe. On the following day he was so sick

that he could not work. He had a chill that day, and it was followed by fever. He had no appetite, and his bowels became quite loose. The pain in his left breast became more severe than before. He had a cough, and expectorated whitish matter. These symptoms became more and more marked, until he was admitted to the hospital. On admission, the patient presented the following symptoms: He was very nervous and excited, and complained of pain in his left breast, especially when he coughed or took a deep breath; he had pains in his legs, arms, and head; his face was flushed, his appetite was pretty good, his bowels were regular, the diarrhoea having ceased. Temperature 103 F.; pulse 130 and weak, but regular. Physical examination revealed rude breathing and exaggerated voice over the middle of the left scapula; sputum is thick and muco-purulent.

Treatment.—Whiskey 3ss., and liq. morphia, U. S., 3j, every three hours.

February 13. Patient is more quiet. His face is still flushed, and his conjunctiva are injected. Last night his temperature rose to 103½ F.; this morning it is 102¾ F.; his pulse is 100, and stronger than when the patient was admitted. He complains of pain in the axillary region on the left side low down, and has also severe pain in the head when he coughs; his appetite is good; bowels have not moved. At noon to-day his temperature rose to 104 F., and a sponge bath was ordered. One hour later his temperature was 103½ F. His pulse continues good.

Physical Signs.—Dullness over the lower half of the scapula and subscapular region on the left side. Bronchial voice and breathing are heard in the same regions.

Treatment the same.

February 14. In the morning the patient's temperature was 101° F.; in the afternoon it was 103¾ F. He is more restless and irritable than he was yesterday. His pulse is 96, full, regular, and strong. He complains very little of pain or dyspnoea. He coughs a great deal, and the abundant expectoration is tinged with blood. Patient is perspiring profusely. His appetite is pretty good. His bowels are confined. Bronchial voice and breathing less marked, and some rales are heard over the base of the left lung.

Treatment.—Whiskey, carbonate of ammonium, fluid extract of convallaria, and U. S. sol. morphia.

February 16. Patient has continued in about the same condition since the last note. He coughs a great deal, and expectorates muco-purulent sputa. Now he has no pain except when he takes a full inspiration. His temperature ranges between 101½° and 103° F. His pulse is 90, and full and regular and strong. Appetite continues to be pretty good. Bowels regular. Physical signs are those of resolution. Treatment the same.

February 18. Yesterday patient's temperature range was from 100½° to 101½° F. This morning it is 99° F. Pulse is 70, full, strong and regular. Eats and sleeps well. Coughs but little. The expectoration is still tinged with blood. Rales more numerous than ever before since the patient has been in the hospital. The same treatment is continued.

February 20. The improvement has been steady

until to-day. This morning the patient's temperature is $99\frac{1}{2}^{\circ}$ F.; pulse 80, full, strong, and regular. He has more dyspnoea, and more pain in the left chest behind. Physical examination shows that the disease is resolving satisfactorily in the lower portion of the lung, but that bronchial voice and breathing have developed in the upper lobe.

Treatment.—Whisky, carbonate of ammonium, and morphine.

February 23. The patient's temperature is still as high as 100° F. His pulse is about 50, and is satisfactory. The patient still coughs and expectorates. He has no pain. He eats and sleeps well, and physical examination shows that the disease is resolving perfectly. Ordered whisky $\frac{3}{4}$ ss, t. i. d., and morphine sulph., gr. $\frac{1}{8}$, once a day.

February 27, The patient has steadily improved since the last note. He is now allowed to go about the ward at will. He has no cough, expectoration, or pain.

Physical examination reveals a normal condition of the lung; his temperature and pulse are normal; he eats and sleeps well.

February 28. Patient discharged from the hospital cured.

Acute Pulmonary Tuberculosis.

Wm. C., age 42, admitted to Bellevue Hospital February 20, 1884. Patient was brought to the hospital delirious from alcohol, and was under treatment for alcoholism in the ward devoted to such patients for three days. He was then in a suitable condition to be transferred to one of the general medical wards, and that change was made accordingly. He then, being in a rational condition, stated that he had had a slight cough for six weeks, and that he expectorated more or less thick, white matter. One week prior to admission to the hospital, the patient had a chill, which was followed by an exacerbation of the cough and expectoration; and he suffered from some prostration. The patient had no dyspnoea, and he did not feel any pain in his chest, except when he coughed very hard. His appetite had failed, his bowels had been constipated, and he had suffered lately from night sweats. He had been addicted to the use of alcoholic spirits, but had not been subject to the symptoms of Bright's disease, so far as could be ascertained.

On admission to the general ward his temperature was $101\frac{1}{2}$, and soon rose to $103\frac{1}{2}$; his pulse was 100 and feeble; his face was flushed, and he coughed and expectorated muco-purulent matter.

Physical signs: Percussion at the right apex gives dullness. Over both sides of the chest there was rude breathing, with numerous sonorous, sibilant and moist râles. Ordered tinct. digitalis.

February 24. Temperature 101 all day. His pulse is stronger; his appetite is fairly good; bowels constipated.

February 25. The temperature range is between 101 and 102 , and generally fluctuates with regularity. It is sometimes higher in the evening, and again the rise will occur in the morning. His pulse is small and feeble; he sweats at night, and feels very much prostrated; he coughs a great deal, with expectoration; he has no pain or dyspnoea; his voice is hoarse.

Physical examination: The râles heard at the former examination have nearly all disappeared, excepting at the apex of the right lung, where they are still numerous and loud. In the same region a peculiar, low-pitched respiratory murmur is heard, the exact nature of which cannot be determined.

Treatment.—Stimulants and medicines to relieve the cough.

March 3. Since the last note, patient has been in about the same condition. Yesterday his temperature was 102° all day, and this morning it is $103\frac{1}{2}^{\circ}$. His pulse is 110, small and feeble. Appetite is poor, and bowels are regular. He coughs a great deal, and has a great deal of expectoration.

The same treatment continued.

March 7. This morning his temperature is lower than usual, it being 99° . His pulse is 120 and very weak. The cough and expectoration continue, and are not relieved by anything. Since the last note patient has been failing rapidly, and now he is in a very weak condition. He vomits profusely. His tongue is dry and coated, and he complains of great thirst. He has had some dyspnoea. No decided change in the physical signs.

March 10. Patient is steadily failing. His temperature ranges between 100° and 103° every day. He is now unable to sit up in bed. He perspires profusely. Physical examination: Over the left apex in front, dullness on percussion, cavernous breathing, and moist râles; over the right apex in front, dullness on percussion, broncho-cavernous breathing, and subcrepitant râles; over the left lung behind, dullness on percussion, rude breathing, and subcrepitant râles; over the right side behind, over the apex, broncho-cavernous breathing and subcrepitant râles; over the base of the lung, rude breathing, with diminished intensity.

March 13. Patient has been steadily sinking since the last note. His temperature has oscillated in its usual manner. His pulse is very feeble. This morning he gradually became more and more stupid, and developed the symptoms of oedema of the lungs, and died.

Autopsy.—Lungs: fresh pleuritic adhesions over the left lung. At the apex of the lung there was a large cavity, and about it there were several smaller cavities. The remainder of the lung was quite solid, and it was studded with large numbers of small tubercles. Over the right lung there were no pleuritic adhesions. The bronchi were dilated, and one bronchus was becoming broken down into a cavity. The upper half of the lung was consolidated, and was studded with a large number of large and small grayish-white masses. The microscope confirmed the opinion that the lungs were the seat of a tuberculous deposit.

Liver: presented signs of interstitial hepatitis and fatty degeneration.

Kidneys: chronic diffuse nephritis.

The intestines were normal, excepting the ileum, which presented one small ulcer. The remaining organs did not present anything worth recording.

Acute General Peritonitis.

Mary K—, aged twenty-two years, admitted January 17, 1884. The patient states that eight days ago she was exposed to cold and wet while

menstruating. After that she had headache, pain in her back, and general malaise. Three days ago she had a severe chill, and was obliged to go to bed at once. The chill was followed by a febrile movement, nausea and vomiting, and severe pain in her abdomen. She also had a slight cough. Her bowels had been loose, but became constipated after the chill. During the last three days her symptoms have steadily increased in severity, *i. e.*, the abdominal pain, the nausea and vomiting, and the febrile movement had become more marked; and, when brought to the hospital, she was quite weak. The abdominal pain was most severe in the right iliac fossa.

Examination on admission to the ward revealed the following symptoms: Temperature, $102\frac{3}{4}^{\circ}$; pulse, 110 and fairly good; abdomen, tympanitic and tender. Patient complained of pain in her abdomen, chiefly in the right iliac fossa. Her tongue was dry and coated. She lies on her back.

Treatment.—Poultices to the abdomen, to be changed every two hours. Magendie's solution of morphine as often as necessary to control the pain.

January 19. This morning her temperature is normal; her pulse 110 and fairly good. Yesterday she was given a simple enema, which moved her bowels. To-day her abdomen is as tympanitic as when she was admitted. She is very much nauseated, and feels drowsy and stupid. Her pain is less severe.

The same treatment is still continued.

January 21. Yesterday, patient's temperature sunk once as low as 98° , but it has been rising slowly since, and is $100\frac{1}{2}^{\circ}$ this morning. Tympanites and abdominal tenderness less marked. Her bowels have moved twice during the last twenty-four hours. She vomits now and then. Her tongue is dry and coated. Pulse 99, and pretty strong. Treatment the same.

January 23. Temperature range since the last note has been between 99° and 100° . She is no longer suffering from nausea and vomiting. Her bowels have not moved since the last note. Tympanites and abdominal tenderness subsiding. She begins to show signs of liking her food. Treatment the same.

January 28. Patient has improved steadily, and nothing has occurred worthy of note. The treatment has not been changed. The quantity of morphine administered is just sufficient to control the pain. The patient has never been narcotized with the drug. To-day some unusual excitement occurred in the ward, and the patient's temperature rose promptly to $103\frac{3}{4}^{\circ}$. Her pulse became more rapid, and she complained of an increased amount of pain in her abdomen, and of considerable uneasiness about her stomach.

January 29. Temperature 101° this morning. Abdomen very tympanitic. Bowels constipated. Patient is much sicker than she was on the day before yesterday.

January 31. Patient has had a pretty high temperature since the 28th inst. To-day it rose to 104° .

February 1. Temperature $98\frac{3}{4}^{\circ}$; pulse between 90 and 100, fairly strong and regular. She feels sick at her stomach, and vomits occasionally. Her bowels are constipated. The abdominal tenderness has diminished very much. She sleeps well.

Treatment.—Wine, ʒij. , every three hours; liq. morphine, U. S., ʒj. , every three hours; and Magendie's solution, p. r. n.

February 2. Temperature rose in the evening to 104° again, and the patient was exceedingly restless, in spite of large doses of Magendie's solution. Her pulse became rapid and feeble. She vomited several times, and had more pain than at any time for a number of days. She was given a simple enema, which relieved her very much. Her bowels had not moved for five or six days.

February 3. Temperature is 99° this morning, and the patient feels much better than she did last night. Same general treatment continued.

February 5. At noon to-day her temperature was as high as $102\frac{1}{4}^{\circ}$.

February 6. Temperature this morning was $98\frac{3}{4}^{\circ}$; pulse 72, and satisfactory. She has some pain in her abdomen still, and still lies upon her back. No vomiting. Abdominal tenderness much diminished, and tympanites not marked. Her bowels move more regularly. Treatment the same as before.

February 9. Temperature and pulse normal. Very little pain in her abdomen now, and no tenderness or tympanites. Bowels move regularly. She looks much brighter, and sleeps well. Ordered wine ʒij three times during the day and during the night; morphine when necessary; poultices removed.

February 13. Patient is allowed to sit up in bed, and partook of a little solid food for the first time since she has been in the hospital. She does not suffer any pain now. Her bowels are inclined to be constipated, and the patient is pretty weak. Treatment the same.

February 19. For a number of days she has been out of bed, and allowed to go about the ward. Now she feels perfectly well, and is gaining in flesh and strength, and eats and sleeps well. She was discharged cured.

Surgical Septicæmia.

Henry J., age 39 years, German, carpenter, admitted to Bellevue Hospital December 1, 1883. Patient came to the hospital with the following history: One week prior to admission he had been injured by one of his tools, and received a lacerated wound upon the anterior surface of his left forearm. This wound was dressed by a physician, and was not looked at again until the patient presented himself to me. On admission to the hospital the patient exhibited a large ulceration on the anterior surface of his forearm, which exposed the superficial layer of muscles. His hand was swollen and oedematous. About the ulcer, the surface of which was in an unhealthy condition, there was a well-marked erysipelatous blush. The patient was accordingly transferred to the erysipelas ward, where he remained one week, and was then sent back to me for further treatment, since he had recovered from erysipelas.

On his return to the ward the patient exhibited the following symptoms: His general condition was pretty good, although he was weak and anemic. During the time he was in the erysipelas ward his temperature was normal, that is to say, it had not risen above 99° F. His left forearm was very much swollen, the palmar surface presenting a large ulcer six by three inches in size.

There were several incisions into the forearm, from which pus flowed. Through the ulcer the finger could be passed, between the planes of muscles and the individual muscles, into extensive sinuses, which were filled with sanious pus. The whole anterior of the forearm was literally riddled by extensive sinuses, which led over to the surface of the bones. The bones were not bare at any point, however. The dorsum of the hand was very cedematous, and at a number of points fluctuation was detected.

Incisions were made into the hand at various points, and a considerable quantity of unhealthy pus evacuated. An aqueous solution of corrosive sublimate, of the strength $\frac{1}{2000}$, was forced into every portion of this extensive region of disease. And the forearm and hand were enveloped in a dressing composed of carbolized gauze, wet in $\frac{1}{40}$ carbolic solution, placed next to the wound, and over all borated cotton.

Patient's temperature rose to 110° F. that evening, and remained high for two or three days. During this time he developed the following symptoms: He became very apathetic; his skin and tongue became dry; his pulse was rapid and feeble; his bowels were constipated; his temperature was at least 100° F., and he had no appetite. His arm was carefully dressed with every attention to antiseptic precautions at least once a day. Drainage was secured perfectly by the introduction of about one dozen rubber tubes into the various sinuses and pus cavities. These tubes were introduced as early as the third dressing of the case. The affected district was constantly irrigated with the corrosive sublimate solution at every dressing. Every part where pus might lodge was carefully irrigated again and again with the mercury solution. And the carbolized gauze was wet in the same solution, and applied wet, after the third dressing. Iodoform was not used for fear of poisoning by it. The forearm and hand were elevated and steadied by a dorsal splint.

This was a case in which constant irrigation of the wound should have been the first choice in the treatment. That plan was seriously considered, but obstacles were in the way of its employment, and it was rejected.

Under this treatment the patient improved until December 18, when after having remained steadily for a number of days at the normal point, his temperature rose to 103° F., and continued high for twenty-four hours. The dressings were changed twice on that day, and the patient's temperature remained as high as 100° F. The strength of the corrosive solution used was doubled. His general condition was not satisfactory. He was very apathetic still, and his tongue was dry and cracked, and his teeth were covered with sordes. His skin was dry and his bowels constipated. His right eye presented a corneal ulcer. Large quantities of sanious pus still flowed from his forearm. The patient's condition was so desperate, and the task of disinfecting the source of his septicæmia was so great and hazardous, that the question of amputation was considered. But it was decided that the patient was so weak that he might perish from the shock of the operation, and that his best chance lay in continuing the treatment already adopted.

Within forty-eight hours after beginning the use of the stronger solution of corrosive sublimate, the patient's temperature fell to normal, and did not rise above 99 again. For about a week the case was dressed twice a day, and thoroughly disinfected with the $\frac{1}{1000}$ solution. After that the dressings were only changed once daily. Patient's general condition improved slowly, but steadily, while the condition of his forearm improved. The purulent discharge from the patient's wounds became smaller in amount and more healthy in character.

January 1. Patient has improved so much that it is not necessary to dress his wounds every day, and the $\frac{1}{2000}$ solution of corrosive sublimate is used instead of the stronger solution. The sinuses and ulcer in the forearm are granulating satisfactorily, and only a small number of drainage-tubes are necessary now. He is much brighter and stronger.

January 12. He was allowed to sit up.

February 1. Discharged, to return as an office case. The sinuses have filled up, and a superficial ulcer only remains of all the extensive granulating surface. The patient returned to the hospital several times to have his arm dressed, but, unfortunately, ceased to come before he should have done so. At his last visit his forearm presented a small, perfectly healthy ulcer. The wrist-joint and the phalangeal joints were in a state of false ankylosis, which yielded readily to passive motion. The patient's hand and forearm might have regained their power and usefulness in a short time, I have no doubt, had passive motion, frictions, and douches been carefully and steadily employed.

In addition to the vigorous antiseptic management of the wound, powerful stimulation with whiskey, wine, and digitalis, was necessary. Iron and small tonic doses of quinine were given day and night, together with the stimulants, and the patient was urged to drink plenty of milk. His bowels were kept open with laxatives. During the most serious period of his illness, the patient received several sponge baths, the temperature of the water used being as high as 104, at least. These baths were given in order to improve the condition of the skin, which was very dry, and did not perform its function properly. They apparently benefited the patient.

In this case there are many square inches of raw surface which was not covered by granulation tissue for a certain time, and which was covered by that tissue later. Upon this surface, every day, for a considerable period, quarts of the aqueous solutions of corrosive sublimate were poured. The bichloride was kept constantly applied to the large ulcer on the forearm, for the gauze used was saturated with the mercury solution. And yet the patient did not at any time show the first symptom of mercurial poisoning. Had strong solutions of carbolic acid been used, instead of the bichloride, there then can be little doubt that we should have had a case of poisoning by that acid.

Rupture of Intestine.

John O'R., age 17, driver, was admitted to Bellevue Hospital in October, 1883. He came to the hospital with the history of having been run over by a truck, the wheels of which passed over the

middle of his abdomen. He was thrown into considerable shock by the accident, but rallied sufficiently to walk to the ambulance, a distance of two or three rods. He did not complain of much pain, and wished to go home, after he had reached the hospital. On the following morning he was transferred to Bellevue. When he reached the ward his pulse was weak. He was not in much pain, and conversed rationally. His abdomen was tender, but not tympanitic, and it did not present any signs of injury, beyond the tenderness. The patient was in shock, although he appeared to be in very good condition. His temperature was normal. Two hours after admission the patient died.

Autopsy twenty-four hours later. Abdomen very tympanitic. The right side of the scrotum is very large, and suggested the existence of a hernia. The usual incision in the median line was made, and gas was found in the peritoneal cavity. There were the usual signs of acute general peritonitis, and the omentum was very much confused. There was no hernial protrusion at any point. But the enlargement of the right side of the scrotum was due to the presence of gas in the sac of the tunica vaginalis. The right inguinal canal was not unusually patent. Beneath the visceral layer of the peritoneum there was gas, which had forced its way to this situation from a vent in the duodenum. This gas, beneath the peritoneum, exhibited a very striking phenomenon. The appendices epiploicæ were inflated with the gas, and looked like a large number of shining glass bulbs suspended from the transverse colon.

Fæcal matter had been extravasated into the peritoneal cavity through the rent in the small intestine. The right kidney was ruptured in several places, and the rupture went through the cortical substance. There was bloody urine in the sinuses of this kidney, but no blood had been noticed in the urine before death. The remaining organs of the body were in good condition.

The observation of the presence of gas in the sac of the tunica vaginalis in this case of ruptured intestine proves that such a thing may occur, even when the inguinal canal is normal. And the fact may become a significant one in some case in the future. For, omitting other signs of rupture of the intestine, the presence of gas in the sac of the tunica vaginalis, in cases where no local cause for it exists, would, in cases where the abdomen was tympanitic, be pathognomonic of rupture or perforation of the intestine. The determination of the existence or absence of a lesion of the intestine when it is suspected, becomes a very important matter, both for the proper prognosis and for the proper treatment of the case.

was used; there was a great deal of pain, and marked neuropathic tendency; insanity in the family in one case. There is one difficulty in the treatment by atropine—that it sometimes causes disagreeable symptoms, especially in delicate women. In one case, where the drug was pushed, it caused such distress that the patient, a woman, refused to take it longer. Atropine in large doses cannot be used in all cases therefore."

Dr. C. L. Dana said, "that Dr. Leszynsky was entitled to great credit in employing atropia against such physiological odds. He believed that the cure was due to the employment of atropia. One point must be borne in mind, and that is that we must select our cases. In those cases where the disease is plainly neurosis, atropine may answer. In many cases, however, the disease appears to be of a peripheral and rheumatic character. Here anti-rheumatic remedies answer better."

Dr. Gibney: "In view of the fact that Dr. Leszynsky administered electricity and other agents, as his report shows, some doubt might be expressed as to the curative effects of the atropine injections. The relationship of cause and effect does not seem sharply enough defined. I have had no personal experience with this drug in torticollis. A few years ago, in a case of rotary spasm of the head, I had a very prompt and excellent result in the use of the fluid extract of gelsemium carried to tonic doses. Dr. Leszynsky certainly deserves credit for the heroic dosage of atropine in this case."

Dr. Birdsall related the history of a case of torticollis treated at the Manhattan Hospital by his assistant, Dr. Perribery, in a child about eight years of age, by the application of as strong a galvanic current as could be endured for from twenty to thirty minutes, on the affected muscles, three times a week, for several weeks, with gradual improvement, which finally terminated in complete recovery. Tincture of belladonna was administered in drop doses, until slight physiological effects were produced. Dr. Birdsall was inclined to credit the curative effect in this case mainly to the galvanism, though he thought that a combination of the method with atropia and that of galvanism, would in general be far more serviceable than either alone.

Dr. Weber: "Was a traumatic effect produced by the hypodermic injections?"

Dr. Leszynsky: "The injections were made into the substance of the muscle, and no traumatic effect was produced. The preparation of atropia used was Morck's, and the solution was freshly prepared every two or three days."

Remarks of Dr. David Webster:

"Mr. President: I have listened to Dr. Leszynsky's paper with much interest. Although I have seen but few cases of wry neck, I have had a good deal of experience with atropine, and I beg leave to question whether the same results might not have been accomplished by smaller doses applied locally. For the purpose of relaxing the sphincter pupillæ and the ciliary muscle, we never give atropia by the mouth or hypodermically, but always apply it locally—to the surface of the eyeball. Less than one twenty-thousandth of a grain applied to the conjunctiva will paralyze the muscles I have named, while it would require a many

NEW YORK NEUROLOGICAL SOCIETY.

(Concluded from page 526.)

DISCUSSION.

Dr. J. C. Shaw: "I have been called three times in consultation in these cases where atropine

times larger dose to produce the same effect if given hypodermically.

"It is remarkable that Dr. Leszynsky's patient tolerated so large a dose as one-sixth of a grain. There is a wide difference in the quantity required to produce the physiological effects of the drug in different persons. I have frequently seen a drop of a four-grain solution, applied to the eye, produce the peculiar scarlet flushing of the face, especially in infants. I also know of a case in which a single drop in the eye caused marked delirium in a young lady, so that she had to be taken home in a carriage. I have had some personal experience with the physiological effects of atropia. I once swallowed what I supposed to be ten drops of Magendie's solution of morphia, to check a diarrhoea while I went to Brooklyn to assist in an enucleation. On the way, I noticed that I felt very strangely, going off into curious dreams, entering into imaginary conversations, etc. When I got to the place of operation, I found on attempting to talk that I could scarcely speak above a whisper, my mouth and throat were so dry. Dr. Agnew noticed that my face was flushed and my pupils dilated. I went home and went to bed, and slept soundly until the next morning. As soon as I awoke, it dawned upon me that I must have taken atropine instead of morphine. As soon as I saw Dr. Agnew, he told me he had arrived at the same conclusion. I found the atropine and morphine bottles side by side on my table. The mystery was explained.

"I once saw a case in the practice of a brother practitioner where one-sixteenth of a grain of sulphate of atropia given with half a grain of morphia subcutaneously produced delirium, lasting for half a day or more. This was in a hysterical lady who was used to hypodermics of morphia without atropia.

"Dr. Leszynsky's method of giving the drug was a perfectly safe one, however, as he cautiously felt his way from smaller to larger doses."

Dr. G. W. Jacoby said: "It was not my intention to make any remarks upon this subject, as the objection which I intended to raise to the indiscriminate employment of galvanism and atropine in the treatment of Dr. L.'s case, has already been made by some of the preceding speakers; but Dr. Gibney's remarks in reference to the facility of producing the physiological effects of atropine, in some cases, by very minute doses, recalls to my mind very vividly a case in which this was also very noticeable. The patient, a girl, aged twelve years, came to me affected with a left-sided tonic torticollis, probably of rheumatic origin. My results with electricity upon other cases having been unsatisfactory, I determined to treat this case by the hypodermic injection of sulphate of atropia. I therefore injected $\frac{1}{16}$ of a grain of the drug.

"This one injection produced all the symptoms of atropine poisoning, ending in a violent delirium, which lasted for ten hours.

"When the patient had recovered from the effects of the atropine, I naturally felt reluctant to continue its use, and began treatment of the torticollis by galvanism. After two weeks the child was discharged from treatment entirely recovered.

"The points which I wish to mark are, firstly, the small amount of atropine necessary in this

case to produce delirium; and secondly, the fact of a cure by self-limitation, or possibly through the action of the galvanic current. Had no ill effects resulted from the use of the atropia, I would probably have continued its use, and my patient recovering, it would have been only natural to attribute this recovery to the use of the atropine.

"Therefore, we cannot be too cautious in drawing our conclusions from a single case, no matter how well observed; and we should be very careful not to use two potent remedies, such as galvanism and atropine, simultaneously, as our skepticism in regard to the efficiency of either one will not be considered scientific proof of the beneficial action of the other."

Dr. Leszynsky, in closing the discussion, said:

"As Dr. Dana saw the patient referred to in my paper, I am pleased to hear that he agrees with me in stating that recovery was due to the employment of the atropia.

"In reporting the history of this case, I expected that the question would arise as to which of the remedies employed had effected the cure, therefore I was not surprised to hear the criticism of Drs. Gibney and Jacoby; and in reply I will state that the number of cells used in applying the galvanic current was from ten to twenty of a Stohrer portable battery. The patient could not tolerate a stronger application, and this was continued for nearly fifteen minutes daily. After the removal of the electrodes, I found that the spasm invariably became more vigorous than ever, and I always allowed about ten minutes to elapse before injecting the atropia.

"I would again direct the attention of the society to the fact that notwithstanding the daily application of galvanism in conjunction with the use of atropia, no improvement was shown until the twentieth day, soon after a rapid increase of the atropia from gr. $\frac{1}{16}$ to nearly gr. $\frac{1}{8}$. Then the improvement became so evident that it can hardly be doubted that the atropia was the important element which effected the successful result. In regard to the use of the bromide of sodium, I can safely say that bromism was not produced. The faucial reflex was frequently tested, and remained well-marked throughout the entire course of treatment.

"Dr. Webster's suggestion may be a very good one if we accept it from an ophthalmological standpoint, but in this class of cases I cannot see what advantage could be gained by the inunction of the oleate of atropia.

"The object in using this sulphate of atropia was to produce paralysis of the trunk and branches of the spinal accessory nerve, therefore it was injected into the substance of the muscle for the purpose of producing its local effects on the motor nerve, although eminent authorities like Ringer and Traser have concluded, after an elaborate series of experiments upon living animals, that atropia paralyzes the motor nerves through its action upon the spinal cord, and not by the action through the circulation. I believe that the oleate if applied locally would produce more rapid constitutional symptoms on account of its speedy absorption; and another objection is that the dose cannot be so accurately determined.

"In conclusion, I will state that the patient remains well, and that no sign nor symptom of spasm has since been shown."

NOMINATION OF OFFICERS FOR ENSUING YEAR.

President—Birdsall, Gray, Morton, W. A. Hammond.

First Vice-President—C. L. Dana.

Second Vice-President—G. W. Jacoby.

Recording Secretary—E. C. Wendt.

Corresponding Secretary—W. M. Leszynsky.

Treasurer—E. C. Harwood.

Councillors (five)—Weber, Seguin, Jacoby, Morton, W. A. Hammond, McBride.

The society then adjourned.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Discussion on the Treatment of Chancroid and Syphilis. (See p. 545.)

Dr. J. William White opened the discussion by saying that there were a few points as to which he differed from Dr. Ashhurst, and to which he would take the liberty of alluding. The treatment of chancroid as proposed by Dr. Ashhurst, had some distinct disadvantages; in the first place it is very painful, and as a matter of fact it is not practicable to etherize one's office-patients, for the purpose of cauterizing chancroids. In the next place, cauterization increases the liability to suppurating bubo. Cases of the latter complication had been much rarer in his practice since he had stopped the indiscriminate cauterization of chancroids, and, in fact, for several years past he had seen them in hospitals, where the cases have been cauterized before admission. Another strong objection to cauterization is that it is extremely apt to produce phymosis, and thus convert an exposed sore into a concealed one much more difficult to treat. If the prepuce were retracted and left so after cauterization of the sore, as recommended in some cases by the lecturer, paraphymosis, an even more annoying complication, would almost certainly result. Then, too, the diagnosis of the sore is rendered more difficult by the cauterization. He did not believe chancroid to be a specific sore in the sense that it is due to a special poison, producing only this form of ulceration, but thought it was due to pus-contagion, owing all its distinctive peculiarities, if it could be said to have any, to the anatomical and histological peculiarities of the parts involved; he was convinced that his cases got well more rapidly when cauterization was omitted than when it was employed. As to cases which *should* be cauterized, they included in his practice only those sluggish sores which refused to take on reparative action under milder stimulus, and those phagedænic sores which are accompanied by rapid and dangerous breaking down of tissue. When a cauterant is necessary, fuming nitric acid was, in his judgment, the one to be preferred. The majority of cases do not require cauterization, and he thought could be best treated by observing the local indications; if the ulcer is inclined to be sluggish, a ten-grain solution of sulphate or acetate of zinc, or a six-grain solution of sulphate of copper, or a thirty to sixty-grain solution of nitrate of silver, will often cause it to take on healthy action; if the ulcer is red with exuberant granulations, or surrounded by an inflamed area, then lead-water and laudanum would be indicated, or a weak solution of zinc in laudanum and rose-

water. Iodoform will often effect a cure more certainly and rapidly than any other remedy, but the objection to it is the penetrating odor so offensive to many persons. He had tried all sorts of perfumes and pharmaceutical disguises without effect, and had finally adopted the plan of advising his patients to tie up a finger with some of the ointment, thus diverting suspicion from the true cause of its employment.

His experience in the Philadelphia Hospital had left him convinced that in the treatment of phagedænic and serpiginous ulcerations, bromine was the best local application; fuming bromine should be applied freely, not only to the surface of the ulcer, but also to all its interstices; it is afterwards covered by oiled lint. He had tried the so-called "horse-shoe" method of counter-irritation in bubo without much benefit, and favored pressure with a shot-bag or half brick covered with flannel.

As to the suppurating bubo, he agreed with Dr. Ashhurst as to the mode in which the incision should be made in opening it, but said that curiously enough it was for a directly opposite reason. He made the incision parallel with the long axis of the body, so that the lips of the wound would *not* gape. When the incision was made parallel with Poupart's ligament, whenever the thigh was extended on the body, the attachment of the fascia lata to the lower lip or wall of the suppurating cavity, and the attachments of the abdominal muscles and fascia to the upper wall, resulted in a wide separation of the wound, making a larger cavity to fill up with granulations, and thereby delaying complete recovery very considerably.

In the treatment of sub-preputial chancroids he would hesitate, for the reasons stated, to retract the prepuce and cauterize, even if it were possible to do so, which would rarely be the case; he considered the paraphymosis, which would almost invariably result, a very objectionable complication; as to packing the space between the glans penis and the foreskin with lint, he believed it in the great majority of cases to be practically impossible, without exciting a degree of pain, inflammation, and hemorrhage, highly prejudicial to the patient: a certain amount of lint might be stuffed in, but he doubted that it could do anything but harm. In his cases of concealed chancroid—or of balanitic or herpetic ulceration with phymosis—he said he directed patients to clean the parts every two hours, injecting with a Taylor's subpreputial syringe, warm water and castile soap; then to wash away all the soap with plain warm water, and then finally to inject a solution of zinc in laudanum and rose-water, five to ten grains of zinc to the ounce of the mixture.

The local treatment of the infecting sore or true chancre was chiefly interesting in regard to the question of excision. If it were believed that the chancre was the first symptom of constitutional syphilis, it would, of course, be illogical to remove the sore with any idea of preventing systemic infection; but if, on the other hand, it were thought that the poison of syphilis, whatever it might be, found its way into the blood, and into the tissues from a point of original inoculation—the chancre—through the medium chiefly of the lymphatics—then it would be entirely philosophical to excise the sore in the hope of preventing constitu-

tional disease. This was the view which he was inclined to favor.

The argument that in the majority of cases excision of the sore fails to prevent general disease, does not in the least affect this view of the matter. It is to be expected that in most instances a portion of the *materies morbi* would have passed beyond the reach of the knife before producing sufficient local symptoms to attract attention. Consequently the majority of cases fail, and always will fail. The possible errors due to mistaken diagnosis, or to the *post hoc ergo propter hoc* method of reasoning, were, of course, familiar to all syphilographers; but it seemed manifestly unfair to include all the reported cases of successful excision of chancre under those heads. The only ways in which the true character of a hard chancre can be determined prior to the occurrence of constitutional infection, are by its microscopical peculiarities and by "confrontation," or inspection of the person from whom it was obtained. Such cases must of necessity be very rare. He had been fortunate enough to have seen two of them—in both of which the sores, which were situated on the prepuce, had been excised and no constitutional syphilis had followed. They were obtained from women with marked secondary syphilis, and were examined microscopically by Dr. Simes, who found them to possess all the peculiarities of Hunterian chancres. Even two such cases, he thought, ought to be given great weight in a fair consideration of the question.

When, however, the sores are not seen at a very early stage of their development, or when they are situated on the glans penis so that their removal will cause deformity, or will give rise to much pain or hemorrhage, he thought the chances of preventing constitutional disease not sufficient to warrant the operation.

As regards the important question of the proper time for beginning constitutional treatment, Dr. Ashhurst's opinion did not seem to him to be consistent with the received facts of syphilography. It was an undisputed axiom that there is no absolute proof of the infecting nature of any given sore except infection itself, as manifested by certain constitutional symptoms. Mercury indefinitely delays or altogether prevents those symptoms, and its administration at the time recommended by Dr. Ashhurst would leave both patient and surgeon in doubt for all time as to the presence or absence of syphilitic taint. As the proper treatment of syphilis involves a prolonged course of mercury, and the surgeon is compelled to insist upon abstinence from matrimony, or, if the patient is already married, the avoidance of conception, the responsibility is very great, and therefore nothing but entire certainty would justify the beginning of treatment. Where confrontation aids the diagnosis, it might, perhaps, be allowable to begin sooner—but, although doubtless it is desirable to give mercury as early as possible, it has been abundantly shown that no great harm results from delaying its administration until the roseola or at least the general glandular involvement has established the fact of syphilitic infection.

After alluding to the various theories for using mercury, he said his own plan was to give it by the mouth, in the form of the protiodide. He

gave four pills a day for two days; then six pills for two days; then eight pills for the same period, and so on, until the patient's gums or his posterior molars became a little sensitive, or his saliva thickened and became more profuse; then the dose was usually divided by two, or if the toxic effect had been produced by a daily dose of only six pills, the subsequent or permanent dose (the so-called "tonic" or physiological dose) was reduced to two-thirds of that, or four pills. He thus determined in each case the quantity of mercury required to affect the new formations of syphilis, as it is well known that embryonic cells or tissues have less resistant power to either therapeutic or pathological forces than the normal cells. This dose was then continued, subject to increase in case of an attack of new symptoms, for a period of eighteen months to two years. Afterwards, he said, he put the patient on the mixed treatment of biniodide of mercury and iodide of potassium for six months. He then stopped and kept him under observation, returning to the mixed treatment if any new symptom appeared, and continuing it for several months.

Going over his case-books for the past seven years, rigorously excluding all hospital and dispensary cases, and all cases which had not been under his care and observation continuously from the primary sore down to the present time, he still had notes of one hundred and seventeen cases with whose personal and family history he was entirely familiar. These cases had all been treated upon this plan. Excluding the minor manifestations of syphilis, such as trifling mucous patches, occasional papular or squamous patches, etc., he found that among these persons there had occurred the following accidents which were fairly attributable to syphilis: four miscarriages, three of which were certainly due to syphilis, and one of which was doubtful; one case of perforation of the hard palate; one of epileptiform convulsions, and two of iritis; in one case the patient lost his penis from phagadenic ulceration supervening in a hard sore at the time of the secondary outbreak, but as he had gone on a long journey and neglected all treatment, this should not properly be set down in the list; not one of all the others had an eruption which betrayed him to his family or friends, and the great majority did not lose a day from their various occupations of business, pleasure, or professional work. In conclusion he said, that having had such results by the continuous plan of treatment, he had not thought it necessary to make any extended trial of the intermittent plan, and consequently could not speak from any large experience with it; nor did he think that, without further evidence upon the subject than he had yet heard, he would modify his present plan of treatment, though the intermittent plan had some distinguished advocates.

Dr. S. W. Gross thought that too much material had been presented for discussion, as there was enough to occupy four or five evenings; he would, therefore, limit his remarks to one or two points. In regard to the treatment of chancroid, he said he would have made about the same remarks as Dr. Ashhurst. He was in the habit of destroying the ulcer, with the triple object of preventing its increase, of preventing the auto-inoculability of the discharge, or the formation of

other sores in the immediate neighborhood of the primary lesion, and preventing the formation of a bubo. His practice was to touch the sore with pure carbolic acid for its anæsthetic effects, and follow this with nitric acid. A dry dressing, in the form of absorbent cotton or picked lint, was then applied, and continued after the slough had come away if the resulting sore was not large; otherwise he employed a mildly astringent wet dressing, say three drops of nitric acid to the ounce of thin mucilage, or two grains of tannin and one-eighth of a grain of sulphate of copper to the ounce of water, or three grains of chloral to the ounce, if the surface be sensitive.

With regard to iodoform, on which the preceding speakers placed great reliance, he had only to say that he had no faith whatever in its action. The device of Dr. White of wearing an iodoform rag on the finger is so well known in this city, that it deceives no one. In his wards at the Philadelphia Hospital, during his connection with that institution, he had invariably found that iodoform dressings retarded the process of cicatrization in simple as well as specific ulcers, the granulations being rarely larger than pin-points. For this reason, with a view to induce a healthy granulating process, he had treated all such ulcers, left by his predecessor, with the nitric acid lotion, with the best results. His own empirical observations in this direction are sustained by some histological peculiarities pointed out by a German experimenter, whose name had escaped him, in a recent number of *Virchow's Archiv*. The writer shows that iodoform prevents the formation of polynucleated epithelioid cells and giant cells in granulations, and in this way accounts for the good effects of the remedy in scrofulous and tubercular granulations. From these experiments we may fairly infer that the formation of the elements essential to the rapid repairs of other granulating surfaces is prevented by the use of iodoform.

In reference to the treatment of syphilis, he agreed with Dr. Ashhurst that it should be by mercury, but he did not employ the remedy in the primary stage, because he wished to know what course each case was going to take. If the advent of the symptoms was masked or retarded, no one could tell from a prognostic standpoint what might occur afterwards. It not unfrequently happens that a man says he was treated with mercury for the initial lesion some months before, that no general symptoms have developed, and asks whether he can marry. In such a case as this the treatment has delayed the appearance of the general symptoms, and the question can only be answered after several months of observation without any treatment whatever. For these reasons he withheld mercury in the primary stage. Before the appearance of general symptoms, he employed the blue pill where the protiodide did not agree. He was also in the habit, he said, of giving opium and tartar emetic to keep up the action of the skin, as the poison should, as far as possible, be eliminated in that way. He gave $\frac{1}{4}$ gr. of opium; $\frac{1}{10}$ gr. tart. emetic, and $\frac{1}{2}$ gr. of protiodide, or $1\frac{1}{2}$ gr. of blue mass, the dose being gradually increased until the tolerance of the patient was established. He thought that the mercurial treatment should be continued for months and months, with an occasional intermission, in

accordance with the rules established by Keyes and other syphilographers.

Dr. John V. Shoemaker said that the use of mercury by the mouth, as recommended by the speaker, would not answer in all cases. In some the alimentary canal will not tolerate the drug; particularly is it the case in debilitated and broken-down persons, who seek treatment in the various dispensaries and hospitals. In others, the mercury at times fails to make any impression, and in such instances, it often passes out of the body by the secretions. He recalled a case of secondary syphilis, in which he administered for several months, first the protiodide, and afterwards the corrosive chloride of mercury, both in small and large doses, without obtaining the least impression either from the drug or upon the lesions on the skin. In this instance he began later to treat the patient by the use of the corrosive chloride of mercury hypodermically, injecting one-tenth of a grain of the corrosive chloride of mercury, dissolved in water, deep into the subcutaneous-cellular tissue, and a cure followed within a few weeks. For the past three or four years he has followed, to a large extent, this plan of treatment with good results, and has never had any unpleasant symptoms follow mercury used in this way. If the needle is in a good condition, a gold one being preferable, and the operator inserts it deep into the cellular tissue, either in the superior or inferior scapular or sacral regions, abscesses will not follow. Dr. Shoemaker then illustrated, upon a patient having secondary syphilis, whom he had brought before the Society from the Philadelphia Hospital for Skin Diseases, the treatment of syphilis by the use of the corrosive chloride of mercury hypodermically. The eczematous condition of the skin, that sometimes follows the inunction method of treatment referred to by Dr. Ashhurst, can very often be avoided, by using, before the inunction of the mercury, a hot-air or steam bath. In treating patients in this manner at the Philadelphia Hospital for Skin Diseases, he always preceded the inunction with either one or the other form of a bath alluded to, and has caused the ointment to be better absorbed, and thus prevented the irritation to the skin. In the treatment of chancroid, he has used the oleate of zinc, dusted over the surface, with most decidedly good impression upon the parts. It has the quality of being odorless, and has a slight stimulating, as well as an astringent action.

(To be Continued.)

The Origin of the Word "Charlatan."

The *Asculapian* says:

It is generally admitted that the word "charlatan" is derived from the Italian word *Ciarlare*, to chatter, to prate. It appears that up to the sixteenth and seventeenth centuries the word was pronounced "chiarlatan." A German journal gives its etymology differently: a Paris physician, Latan, went through the town in a chariot containing his drugs, and in which he examined his patients. This caused the expression "Voilà le Char de Latan," which was subsequently corrupted into "charlatan."

EDITORIAL DEPARTMENT.

PERISCOPE.

Perineal and Penile Fistulæ: Scrotal Bisection.

In the *Brit. Med. Jour.*, February 23, 1884, Mr. Richard Davy says:

During the last year, I have operated on two most severe and obstinate instances of penile and perineal fistulæ; the results gained have been so satisfactory as to warrant me in directing your special attention to the surgical treatment of these miserable affections. I propose (1) to consider the subject of traumatic stricture of the urethra; (2) to briefly narrate the clinical facts; and (3) to offer some suggestions with regard to the operative treatment.

A man receives a severe blow on his perineum; hæmaturia or retention of urine follows; the acute symptoms subside; but the injury mechanically stamps that urethra with the origination of stricture; and slowly, but surely, the calibre of the urethra diminishes. The osseous arch of the pubes, and the tense, unyielding triangular ligament, favor the intensity of the blow by affording counter-resistance; and this is exemplified in some accidents by well-marked comminuted fracture of the subpubic arch, associated with rupture of the membranous portion of the urethra. Let me pass over the tedious interval (it may be months or years) between the date of the accident and the formation of the traumatic stricture, and state merely that this interval represents the period of its growth; the man complains of increasing difficulty of micturition, straining, incontinence, and loss of energy, during the time that his urethra is becoming smaller at the point, and larger on the vesical side of the stricture; his bladder is becoming generally hypertrophied; and his kidneys hyperæmic; in consequence of the ponding back of the urinary excretion. By reason of a persistent strain on an originally bruised urethra, the mucous membrane gives way, and nature relieves herself by establishing one or more fistulous tracks; these are the result of urine leaking through the damaged pipe, and setting up irritation in the perineal and penile districts, gradually showing this infiltration by great general uneasiness and concomitant abscesses. So soon, however, as the skin breaks, the urine gushes through, and the banks of the sinus become gristly and indurated; thus fortifying the adjacent structures from further extravasation.

But, at this stage, pray consider the man's misery; his bed-linen wet by night, his shirt and trousers by day; his groin, thighs and buttocks chafed; his never-ceasing consciousness of not being as other men are; his own smell, and that of his garments, nauseous to himself and repulsive to his neighbors! Would not any one of us feel life intolerable under these hard conditions? and would we not risk everything, and submit to anything that held out reasonable and welcome hope to such distress of mind and body? These patients have done so; and I will now, secondly, give you their short clinical histories.

Case 1. *Penile and Perineal Fistulæ: Traumatic*

Stricture of Urethra: External Urethrotomy and Bisection of the Scrotum: Recovery—J. O., aged 44, blacksmith, residing in Cornwall, married, was admitted into Mark ward, under my care, on October 19, 1882. He had been a healthy, strong man. In 1870, when shoeing a colt, he was kicked in the scrotum and perineum. Two weeks afterwards, he felt pain and urethral discomfort in micturition, and he noticed that his stream was diminishing in volume, and his propulsive power lessening; the act being accompanied by much straining, and occupying more and more of his time. These symptoms went on until 1879; when, after intense pain, two fistulæ opened anteriorly and posteriorly to his scrotum; the perineal fistula came first, and carried fully one-half of his urine. The penile fistula dribbled; and the natural channel conveyed about one-half *per meatus*. He was the subject of a right inguinal hernia, and had a patent left abdominal ring; both groins suffered severely from the straining, but the hernia was not originally caused by it. No instrument could be passed *per urethrum*. His condition was desperate; and he was sent to London, as a last resource, on the recommendation of his clergyman. On October 24, 1882, the man was placed under the influence of chloroform. A grooved director (almost straight) was passed down the urethra to the face of the stricture at the membranous part, and the knife was directed from the penile fistula, along the median line of the whole of the scrotum, until the director emerged at the perineal wound; the stricture was recognized and cut across, and a sound passed into the bladder from the perineum. On withdrawing the director from the meatus, a No. 12 retentive catheter was passed from the meatus out at the perineum, and again from the perineum into the bladder, so as to ensure that the newly-opened line was the channel occupied by the elastic instrument. This elastic instrument, or one like it, was retained in the bladder for nearly four weeks at a time, until January 9, 1883, when the patient was quite well; all fistulæ closed, no scrotal pain nor discomfort. No. 12 sound was passed along the whole urethral tube. He had perfect control of urine by day and night.

On January 16, 1883, he left Westminster to pursue his business in Cornwall as a blacksmith.

Case 2. *Stricture of Urethra: Traumatic; Scrotal Fistula and Infiltration: Bisection of the Scrotum and External Urethrotomy; Recovery*.—John L., aged 38, married, a chairmaker, was admitted into Mark Ward, under my care, on August 22, 1883. In 1868, he fell off a rick which he was thatching, and injured his perineum by falling on some wood. He did not pay any particular attention to the accident, and thought it would pass off; but, for the last six years, he had found much straining and inconvenience during micturition; and, in the early part of July, 1883, an abscess formed by his right erector penis muscle and scrotum, and was opened by Mr. Turner, of High Wycombe. Mr. Hayden also saw him, and performed suprapubic puncture of the bladder, and caused his urine to pass through a catheter for a fortnight by

the suprapubic aperture. As the urine persisted in traversing the scrotal fistula, he was sent to the Westminster Hospital. On August 27, I bisected the whole scrotum, and laid the stricture open freely, but with much care; passed No. 10 red elastic catheter from the meatus into the bladder, and retained it *in situ* for a fortnight. The fistula entirely closed, and the wound healed most kindly; he left the hospital on October 4, 1883, and passed the whole of the urine freely through its natural channel.

On October 27, 1883, I again saw the patient, and, in every respect, he was sound and quite well.

Let me now offer some practical observations on the subject of operative treatment in these loathsome cases. The first object of the surgeon must be to restore to its normal calibre the channel of the urethra, and maintain such dilatation. In some cases, notably those under the care of Mr. Barnard Holt, such dilatation of the stricture has sufficed also for the cure of the fistulæ. When I acted as Surgical Registrar to this hospital, I had many opportunities of seeing fistulæ close, on the renovation of the urethra by immediate dilatation. In the event of the fistulæ remaining intractable and patent (excluding the operation of perineal section or external urethrotomy), the best course to pursue is to divert the stream of urine temporarily from the fistulous track (*vide Surgical Lectures*, subject viii., pages 58 and 59, "On Puncture of the Bladder *per Rectum*"), either by suprapubic aspiration, or by puncture *per rectum*, or by opening the urethra somewhere on the vesical side of the stricture. I have tried them all, and have even taken pains to pump out the urine from the bladder for two or three days at a time, and to forbid any urine to be retained in the bladder, or to be expelled by involuntary spasm or change of posture. Some mechanical operation with this intention does certainly aid the chance of union, either with or without a plastic operation. Some of my cases have been very successful, others most annoying failures; and, had I my choice of only one operation for this class of cases, I should, from experience, choose "perineal section," and I will now lay before you my reasons for this preference.

1. The signal benefits gained from perineal and scrotal section in these two cases of stricture and fistulæ, respectively of twelve and fifteen years' duration from date of accident.

2. The reflections induced by watching how well and satisfactorily the wound for lithotomy unites in moderately healthy subjects, although no special means beyond care and cleanliness are adopted.

3. The free drainage granted right and left to the swampy tissues involved, and the marked softening and improvement of the glistly channels of urine. Moreover, by this simple but efficient free outlet, the maximum amount of rest is given to the divided stricture during micriturition.

4. The total absence of interference on the part of the surgeon during recovery, thereby economizing mental and physical suffering on the side of the patient.

5. No important structures are divided, so far as the scrotum is concerned, by strictly keeping

in the middle line (*vide Lancet*, May 20, 1882, Mr. Gould's case of Amputation of the Penis).

By this scrotal extension of the perineal section, originated by that grand surgeon, Syme, there are some cases, hitherto refractory, to be cured by our art. The operator challenges, in one continuous line, his patient's stubborn foes; and, by concentrated action, cuts his way through them all (fistulæ, sinuses, swamp, gristle, and stricture); and, quoting a parody which has been applied truthfully to allied conduct, he puts all his little troubles into one big one.

An Attempt at Suicide by Cardiac Transfixion.

The following case is recorded in the *Edinburgh Med. Jour.*, March, 1884:

The patient, C. S., was an elderly lady, in confinement in an asylum on account of her suicidal proclivities. For many years she had suffered intense and almost constant agony from neuralgia, and at a later period mental anxiety on account of domestic matters was superadded. Quite suddenly the neuralgia ceased to trouble her; but coincident with its disappearance, and replacing it, came the melancholia under which she now labors. She became dull, listless, and apathetic, and the one end and aim of her life seemed to be the termination of it by her own act. Probably she was under the influence of certain delusions even then, but she gave no distinct expression to them for many months—indeed, not till after the occurrence I report, and then only on a very few occasions. Her intelligence remained almost as clear as ever, and this rendered it all the more difficult to take sufficient precautions to prevent her accomplishing the object of her desires. Every effort was made to keep her at home, but several determined and very nearly successful attempts at suicide on her part while there induced her relatives to remove her to an asylum.

For some months after her admission she remained in very much the same state—was dull and listless, but very rational in her conversation and her letters. The close and careful watch kept on her prevented her actually attempting any injury to herself, but there was no reason to believe that the tendency was less strong than before. At last she saw her opportunity. Just after getting into bed she was observed to have become suddenly and violently ill, and medical aid was summoned at once. On its arrival she was found to be quite unconscious, very pale, skin cold and clammy, pupils widely dilated, but there was no conjugate deviation present; the features were drawn and altered, and the head was rolled rhythmically from side to side, patient moaning slightly at times. The radial pulse on the right side was very weak, that on the left almost imperceptible—rate, 78 per minute. The left arm and leg were quite paralyzed, so far as could be made out. The right arm was lifted and let fall feebly and aimlessly now and then. She had vomited a little, but no deleterious substance could be detected in the rejected matter by the rough examination possible at the time.

On palpation over the præcordia, the cause of this rather puzzling condition was discovered. A knob about the size of a large pea was felt adher-

ing to the chest-wall, in the situation of the apex beat, and this proved to be the head of a large steel shawl-pin, about $3\frac{3}{8}$ inches long, which the patient had succeeded in secreting, unobserved by the attendant in charge, and which she had thrust right into the chest, at the situation mentioned above, the part embedded being directed slightly upwards and inwards, and measuring about $2\frac{3}{4}$ inches. It was at once removed, and stimulants administered, and almost immediately the heart's action began to gain in force. The pulse became stronger and steadier, and consciousness slowly and gradually returned. For some time there was very urgent dyspnoea, and patient complained much of pain in the precordia, but these unfavorable symptoms diminished as time went on, and after an hour had passed she was much better: the paralysis of the left side had disappeared; the pulse was steady, and of fair strength—rate, 108 per minute; and she was quite conscious of what transpired around her. Four hours after the occurrence, she was sick again, and vomited a little; but this soon passed off, and she fell asleep, and slept at intervals during the rest of the night, stimulants being given frequently in small doses. On the following day she complained of some pain at the site of puncture, and of headache, but was otherwise pretty well, and her recovery after this proceeded without interruption. Some months have now elapsed, and no trace of the injury can be detected.

It appears to be practically certain that the pin transfixed the heart, probably at a point very near the apex of the organ. The elaborate analysis of cases of heart wounds in Holmes's *System of Surgery*, vol. ii., pp. 599–610, renders it unnecessary for me to do more than simply to refer to it for a *résumé* of the subject. Perhaps the case alluded to in that article, of the thrusting of a long gold needle into the heart, is the most similar to mine on record, but fortunately the issue here was very different. For the benefit of the curious in such cases, I may be permitted to refer to the ingenious Mrs. Aphra Behn's account, in *Oroonoko*, of the tigress which lived comfortably for many years with seven bullets of lead in her heart. After this, it is not surprising that the authoress should announce heart-wounds to be anything but necessarily fatal.

Perhaps the chief interest of the case recorded here is its bearing on Mr. Westbrook's proposal to aspirate the right auricle in cases of acute and intense pulmonary congestion, with over-distention of the right side of the heart. The part of the organ to be operated on is, of course, different from that involved in this experiment, but it is not quite clear that the results would be less serious; and even Mr. Westbrook appears to prefer to adopt the measure only in cases where all chance of recovery has disappeared. Perhaps other less heroic plans might obviate the disappearance of all chance of recovery. If not, it is doubtful whether it is worth while to torment the last hours of a patient who is already moribund. At any rate, I am convinced that my patient made a very narrow escape—so narrow that I cannot but think cardiocentesis out of the range of practical surgery.

The Micro-Organism of Purpura Hemorrhagica.

To the Pathological Society of London (*Lancet*, February 23, 1883), Mr. Watson Cheyne showed micro-organisms from two cases of purpura hemorrhagica. Dr. Russell's case was that of a girl, aged twelve years, who had a purpuric eruption with pain in the joints, epistaxis, and bleeding from the ear. The temperature was 104.6° on the morning of death. There were numerous ecchymoses in the skin, and hemorrhage into the pelvis of the right kidney. Sections of the heart showed extensive hemorrhage beneath the exocardium. The capillaries were plugged with small bacilli arranged in colonies—a few were isolated, the typical mode of grouping was evidently in colonies. The walls of the vessels were ruptured; there was no evidence of inflammation. The bacilli measured $\frac{1}{7000}$ in. in length and $\frac{1}{20000}$ in. in diameter. Spores or unstained roundish areas also existed in the rods. There was no peculiarity in the staining reactions. Methylene blue was the best dye. The distension of the wall of the capillaries seemed to show that the bacilli had been growing in the blood for some time. The probable cause of the hemorrhage was the plugging of the vessels with bacilli. Micro-photographs were shown. Dr. Pye-Smith's case was a boy, aged fourteen, who had one brother who bled much at the nose. The patient bled from a boil at first; afterwards there was constant bleeding from the gums, nose, and also into the conjunctiva. The temperature was 98° . After prolonged use of local styptics the bleeding ceased. The anæmia produced was intense, and the patient died. There was hemorrhage from an erosion of one small ulcer in the stomach. There were small subarachnoid hemorrhages. The testes, lungs, brain, skin, serous and mucous membranes were all affected. The lungs, tonsil, and heart were examined. The pulmonary alveoli were full of blood, and the vessels contained colonies of micro-organisms, the capillaries and some larger vessels were completely blocked with swarms of streptococci which exhibited a typical chain formation. These micrococci were $\frac{1}{7000}$ in. in diameter. There were no free micrococci. No inflammation and no necrotic layer were seen around the plugged vessels. Sections of the tonsils showed several of the vessels plugged with streptococci. The importance of the observation of two cases of idiopathic purpura hemorrhagica associated with the presence of micro-organisms was very great. These micro-organisms formed colonies, other kinds did not form vascular plugs (except the typhoid bacillus). The question whether there was an entrance of specific germs from without, or whether organisms had penetrated into the blood from the alimentary tract, was considered.

Dr. Pye-Smith referred to the fact that no change had yet been found in the blood-vessels of cases of purpura, though such change might be expected to exist.

Dr. Bernard O'Connor asked whether micro-organisms had been found in the blood.

Dr. Angel Money had not found micro-organisms in the blood in two cases he had examined.

Dr. Stephen Mackenzie said we ought not to come to the hasty conclusion that organisms were present in all cases of purpura; and Mr. Cheyne had exercised scientific caution in limiting his in-

ferences to his actual observations. There was no probability of any specific organism being engendered in cases of "iodic" purpura.

"Chloride of Methylene."

The *Brit. Med. Jour.*, April 12, 1884, tells us that MM. Regnaud and Villejean have published the results of two investigations into the nature and action of chloride of methylene, from which they have drawn several interesting conclusions. They set themselves, in the first place, to determine the relative constitution of the substance known as chloride of methylene in England, as compared with a standard specimen of chloride of methylene (CH_2Cl_2) prepared by themselves. The density of the former at 15°C . (59°F .), was found to be 1.363, and of the latter 1.334, which pointed to the probability that the English product was not exclusively composed of chloride of methylene. Further, the standard chloride of methylene boiled at a temperature of 40.4°C . (104.7°F .), while the other did not show any signs of ebullition until 53°C . (127.4°F .) was reached. At that temperature, most of the English substance passed over into the condenser, leaving a residuum which proved to be methyl alcohol. That part which passed over was found to be chloroform. The substance, therefore, known in this country as chloride of methylene is a mixture of methyl alcohol and chloroform, the proportions of each component being one part of the former to five of the latter. The second part of the research was devoted to a study of the physiological effects of chloroform (CHCl_3) and of chloride of methylene (CH_2Cl_2). It is unnecessary to make any remarks upon the action of the former substance, but the results of the inquiry regarding the latter are novel and interesting. From fifteen experiments upon dogs, the following picture is drawn as giving the typical sequence of phenomena. After half a minute of inhalation, agitation began with whining. After one minute and a half, there was dilatation of the pupils and nystagmus. After two minutes, the eye-reflexes were abolished, and general insensibility set in. In three minutes clonic movement of all the extremities and the tail set in. At four minutes inhalation was stopped and the dog set free. The clonic movements ceased. In six minutes the eye-reflexes returned; there was persistent contracture of the jaws. At seven minutes, there was an epileptiform attack. At eleven minutes the phenomena diminished in intensity: the animal tried to get up, but the paws seemed to be in the same condition as in strychnia poisoning. At twenty-two minutes, the jaws could not be opened; there was convergent strabismus. Up to about half an hour, the symptoms of intoxication gradually passed off, but, although the jaw could be opened, the animal could not raise its head, and paid no attention to its keeper's summons. These results prove that the substance known in this country as chloride of methylene has nothing in common with true chloride of methylene except the name; that the action of the English product is solely due to its contained chloroform; that the effects of true chloride of methylene are entirely different from those of chloroform; and, finally, that the action

of the former is so disturbing that it never can be used in surgical practice.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT MEDICAL LITERATURE.

—In a reprint from the *American Practitioner*, Dr. W. O. Roberts, of Louisville, describes a knife-wound of the intestines, and in passing vindicates the right of Dr. S. D. Gross to the honor of first defining the proper treatment. His words are:

"What Dr. Gross suggested, now more than forty years ago, as applicable to extensive wounds of the gut, has, as is well known, recently been widened so as to embrace all penetrating injuries of the bowel, but the honor belonging to the entire procedure is now claimed by others.

"I submit that it belongs to Dr. Gross."

—The *American Journal of Ophthalmology*, vol. i., No. 1, starts out with an excellent assemblage of articles, and with fine paper and typography. It promises well for the future. Issued on the 15th of every month by J. H. Chambers & Co., St. Louis; editor, Dr. Adolf Alt. Price, \$2.50 per year.

BOOK NOTICES.

Elements of Modern Chemistry. By Adolphe Wurtz. Second American Edition. Translated by Wm. H. Greene, M. D. 8vo., pp. 770. Price, \$2.50. J. B. Lippincott & Co.

The success of this treatise in France, and the distinguished position held by the author, were sufficient reasons to anticipate a welcome by English-speaking students, and this has been fully realized.

In the present edition, important changes have been introduced in order to represent the modern views of chemical science. Of these we may mention a new classification of the metals in accordance with the present theories of atomicity; observations on the significance of chemical energy; an explanation of the remarkable law discovered by Mendeleeff by which the properties of bodies are shown to vary with their atomic weights according to the theory of periodic functions; and a number of other novelties. Extensive additions have also been made to the sections on organic chemistry. We have no doubt that the treatise will continue to be a favorite text-book with students, and it gives us pleasure to bring it prominently to their notice.

AN OBSTETRIC CASE

(Price, \$15.00),

OR

AN ELECTRIC BATTERY

(Price, \$25.00),

AS PREMIUMS.

Any subscriber to the REPORTER who will send us before the 1st of July the names of *three* new subscribers with their *yearly* subscriptions (\$15) or *five* new subscribers with \$25.00, will receive, for the three, an Obstetric Case complete, and for the five, an Electric Medical Battery complete. They are new, of the best make, and of guaranteed excellence. The new subscribers will receive the REPORTER *free* from the date of the remittance until July 1st next.

Address Dr. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA, PA.

PARTURITION IN CENTRAL AFRICA.

From a most interesting paper on this subject by Mr. R. W. Felkin, in the *Edinburgh Medical Journal*, April, 1884, we can form some idea of how our semi-civilized neighbors in Central Africa pass through that period, which a false and enervating civilization has made so critical to the women of America.

In the Madi district, when a woman thinks that she is near the time of delivery, she abstains from meat, but eats a great deal of vegetable food. She cleans up her hut and sends her children away, and when labor commences she walks around the hut, while a friend places a deep layer of dry sand outside, a short distance from the door. The woman sits down, places her feet against stakes driven into the ground, and clasps her legs, while friends take turns in supporting her back, and in kneading and rubbing the abdomen. The cord is cut at about four inches from the child's body, by a stone knife, as a rule, but sometimes it is bitten. Should it bleed, the woman in charge takes the cord in her mouth and squeezes it between her teeth till all hemorrhage ceases; but it is never tied. The woman is not permitted to eat meat for a week or more after confinement; she suckles the child for two years, and has no connection with her husband for six months after its birth.

In the Bongo district an altogether different custom prevails. A branch of a tree is laid horizontally between two other trees, so that a woman can just grasp it firmly. When the pains come on, she seizes the branch, places her feet apart, and bears down; in the intervals she walks about. The mother and child both receive baths immediately after the completion of labor, the placenta being carried by a woman, who dances before the party, and throws it into the stream as far as possible.

Here, too, another custom is prevalent. A hole is dug in the ground, in which a fire is lit; on this fire a pot is placed, containing a decoction of herbs; the woman squats over this, and allows the steam to moisten and soften the passages. It is held in great repute for making labors easier.

He also notes that a like plan, other plants being used, is very generally adopted by Arab women, and natives married to Arabs, before coitus. It is said to contract the parts, and cause great desire.

Speaking of operative interference, he says :

"So far as I know, Uganda is the only country in Central Africa where abdominal section is practiced with the hope of saving both mother and child. The operation is performed by men, and is sometimes successful; at any rate, one case came under my observation in which both survived. It was performed in 1879, at Kahura. The patient was a fine, healthy-looking woman of about twenty years of age. This was her first pregnancy. I was not permitted to examine her, and only entered the hut just as the operation was about to begin. The woman lay upon an inclined bed, the head of which was placed against the side of the hut. She was liberally supplied with banana wine, and was in a state of semi-intoxication. She was perfectly naked. A band of mbugu or bark cloth fastened her thorax to the bed, another band of cloth fastened down her thighs, and a man held her ankles. Another man, standing on her right side, steadied her abdomen. The operator stood, as I entered the hut, on her left side, holding his knife aloft with his right hand, and muttering an incantation. This being done, he washed his hands and the patient's abdomen, first with banana wine and then with water. Then, having uttered a shrill cry, which was taken up by a small crowd assembled outside the hut, he proceeded to make a rapid cut in the middle line, commencing a little above the pubes, and ending just below the umbilicus. The whole abdominal wall and part of the uterine wall were severed by this incision, and the liquor amnii escaped; a few bleeding-points in the abdominal wall were touched with a red-hot iron by an assistant. The operator next rapidly finished the incision in the uterine wall; his assistant held the abdominal walls apart with both hands, and as soon as the uterine wall was divided he hooked it up also with two fingers. The child was next rapidly removed, and given to another assistant after the cord had been cut, and then the operator, dropping his knife, seized the contracting uterus with both hands and gave it a squeeze or two. He next put his right hand into the uterine cavity through the incision, and with two or three fingers dilated the cervix uteri from within outwards. He then cleared the uterus of clots and the placenta, which had by this time become detached,

removing it through the abdominal wound. His assistant endeavored, but not very successfully, to prevent the escape of the intestines through the wound. The red-hot iron was next used to check some further hemorrhage from the abdominal wound, but I noticed that it was very sparingly applied. All this time the chief 'surgeon' was keeping up firm pressure on the uterus, which he continued to do till it was firmly contracted. No sutures were put into the uterine wall. The assistant who had held the abdominal walls now slipped his hands to each extremity of the wound, and a porous grass mat was placed over the wound and secured there. The bands which fastened the woman down were cut, and she was gently turned to the edge of the bed, and then over into the arms of assistants, so that the fluid in the abdominal cavity could drain away on to the floor. She was then replaced in her former position, and the mat having been removed, the edges of the wound, *i. e.*, the peritoneum, were brought into close apposition, seven thin iron spikes, well polished, like acupuncture needles, being used for the purpose, and fastened by string made from bark cloth. A paste prepared by chewing two different roots and spitting the pulp into a bowl was then thickly plastered over the wound, a banana leaf warmed over the fire being placed on the top of that, and, finally, a firm bandage of mbugu cloth completed the operation.

"Until the pins were placed in position the patient had uttered no cry, and an hour after the operation she appeared to be quite comfortable. Her temperature, as far as I know, never rose above 99.6° F., except on the second night after the operation, when it was 101° F., her pulse being 108.

"The child was placed to the breast two hours after the operation, but for ten days the woman had a very scanty supply of milk, and the child was mostly suckled by a friend. The wound was dressed on the third morning, and one pin was then removed. Three more were removed on the fifth day, and the rest on the sixth. At each dressing fresh pulp was applied, and a little pus which had formed was removed by a sponge forced of pulp. A firm bandage was applied after each dressing. Eleven days after the operation the wound was entirely healed, and the woman seemed quite comfortable. The uterine discharge was healthy. This was all I saw of the case, as I left on the eleventh day. The child had a slight wound on the right shoulder; this was dressed with pulp, and healed in four days."

Mr. Felkin, rather contrary to have what we

been generally led to believe of these tribes, tells us that so far as he knows, labors are by no means so very easy in this part of the world, and are certainly not the painless, pleasurable affairs which some writers would have us believe. When a hard labor occurs and a woman remains a very long time undelivered, the aid of a man is called in. He, however, uses no instruments; and should he fail, *which, he was informed, hardly ever happens*, mother and child perish, for abdominal section is not in vogue here. He was unable to ascertain what means the man employs to assist delivery.

But the italicized words convey to us the idea that the act of parturition is very seldom a *fatal* act among the semi-barbarous natives of Central Africa.

CAPITAL PUNISHMENT.

There can be very little doubt in the mind of any thinking man, that capital punishment is but little better than a relic of barbarism. Experience seems to have demonstrated that the purpose for which it was instituted, that of deterring those contemplating murder from committing the crime, has not been realized; and the question of abolishing it altogether is being now seriously agitated in England.

When one man murders another he almost invariably does so, under the stimulus of passion that makes him for the time being well-nigh irresponsible (though we do not wish to be understood as advocating the much-abused plea of temporary insanity); some real or fancied wrong, or some benefit which he expects to derive from the death of his victim, so works upon his intellect that he is almost, if not quite, irresistibly urged on to the commission of the crime. Or it may be that the deed is motiveless, and in such instances we generally note that the intelligence of the murderer is but little, if any, above that of the brute creation.

On the other hand, when a man has been tried by a jury and convicted, the circumstances are vastly different. Here twelve men, presumably intelligent, and a judge who, on account of his acknowledged intelligence, has been elevated

above his fellow men, without the stimulus of passion, revenge, drunkenness, imbecility, or prospective gain, deliberately and calmly direct that another man (the sheriff's officer) shall kill the poor wretch before them. Does this not seem very much like judicial murder, rendered more repulsive from the absence of motive for the act? It is true that the law of the land calls upon these men to perform this dreadful duty: but is it not a barbarous law, that has no good reasons for its existence? Is not the London *Lancet* right when it speaks of "the pitiful and degrading spectacle of a great nation strangling its malefactors like so many dogs?"

Again, it has happened that circumstantial evidence has hanged innocent men, which is a possibility too horrible to be calmly contemplated.

Would it not be better to condemn murderers to imprisonment for life in such a well-built and well-guarded prison that escape would be impossible; to force each man therein to labor at that particular work which observation should have demonstrated to be the most uncongenial to him, and at certain intervals, say weekly or monthly, to march these criminals, heavily shackled and well guarded, through the streets of the city in which they are confined? By thus constantly reminding would-be murderers of the penalty of their crime, we imagine that a much more deterring effect would be realized, than by presenting to them the remote prospect of a tragic and exciting death, preceded by the mistaken, but very general sympathy of the public. To some miserable men the idea of a disgraceful death has no horrors; for to their hardened and brutal natures, *disgrace* is an incomprehensible word, while death, to their irreligious minds, brings but relief from a miserable and wretched life which they prize but lightly.

If, however, capital punishment is a necessity to collective civilized life (which, for the reasons already adduced, we very much doubt), can we not accomplish it in a less barbarous and revolting way than by strangling a man to death or breaking his neck?

That we can, and how to do so, will readily

suggest itself to our readers. We will only mention one plan which seems to us to partake less of barbarism than any other—the hypodermic injection of fatal doses of morphia.

Let us remember that vengeance belongs to a higher tribunal than any human court and jury, and that hanging does not *deter*, and that, therefore, the only two arguments that could be adduced for the perpetuation of this uncivilized procedure are robbed of their potency.

CHANCROIDS AND SYPHILIS.

We desire to call attention in an especial manner to the lecture on this subject, which forms the leading article in this week's issue, and to the able discussion which followed.

In view of the wide-spread evil influence of syphilis, both directly as *syphilis*, pure and genuine, and indirectly as the undoubted syphilitic influence upon all diseased conditions, with which every practitioner is familiar, there is no subject before the medical profession to-day that possesses more practical interest than the treatment of syphilis.

Dr. Ashhurst's admirable paper should be carefully read and re-read, as should also the opinions of those who discussed his paper; for they have all had immense experience with this disease, and are well calculated to teach us about it.

The two points upon which the greatest diversity of opinion seemed to exist, are points that will never be positively settled to the satisfaction of all, but will ever remain in dispute, being determined according to the opinion or experience of each individual physician. We refer to the excision of the chancre, and to the institution of immediate specific treatment.

The weight of recorded evidence seems to demonstrate that the excision of the chancre does not tend to prevent systemic infection, yet there are certain good authorities who still advocate it as a prophylactic measure.

The objection which Dr. White urges to the immediate specific treatment has more force from the side of the physician than from that of the patient.

mercury and iodide of potassium possess the

power of controlling the poison of syphilis after it has become manifest, it is but fair to infer that they also possess the power to throttle this poison in its incipency; and as we know that prevention is better than cure, would it not be better to counteract this poisonous influence before it has marshaled its forces to make a savage onslaught on the system?

It is true that by so doing we, in some cases, would never know whether the man would have had syphilis or not; but what difference does this make, if he *does not have it*? As far as losing our guiding point in reference to marriage, there is not so much force in this argument; for if a man comes to us with a primary sore that would make syphilis a dim presumption even, prudence would dictate to us to advise against immediate marriage; and if we institute a course of specific treatment, which, as the speaker says, may *mask* the disease, we can, after the system has become impressed with the drugs, discontinue the treatment, remove the mask, and allow the disease to become manifest, if it has not been controlled or eradicated by the treatment.

The point that strikes us most forcibly is, that we cannot *wait* for developments when we have to deal with such a terrible disease as syphilis.

NOTES AND COMMENTS.

Hot-water Injections in Gonorrhœa.

Dr. S. C. Gordon has had most excellent results from a method of treatment which he thus describes in the *New York Med. Jour.*, April 19, 1884:

I filled a fountain-syringe with a quart of water at a temperature of about 100° F., and, with one of the small tubes introduced into the urethra as high as I could push it, I injected it and allowed it to run back into a vessel. It ran back by the side of the tube, washing the urethra as far as it was thrown up. The first trial acting as a sedative, or at all events giving no pain, I filled the fountain again, this time increasing the temperature about 10°. I found that, by asking the patient to strain a little as if urinating, the urethra could be sufficiently dilated to allow the water to pass into the bladder, and in that way I filled and

refilled the bladder several times, allowing him to pass it off himself each time. The relief afforded by this second injection was immense, and from that moment the dysuria ceased to be an element of much trouble.

This douching I continued twice each day, and in three days I had the pleasure of seeing my patient practically relieved of *all the unpleasant symptoms*. A very slight discharge remained, but a repetition of the same treatment for a few days more completed the cure. From the first day of the injections no anodyne was needed, and no medicine was given. The chordee was relieved, the burning sensation removed, and the patient happy.

In conclusion, he says: "I can give only a brief summary of the cases in which I should expect the most satisfactory results from this mode of treatment:

"1. I should hope, and confidently expect, to abort, in from three to five days, a large majority of cases that were treated as soon as the first well-known symptoms appeared. In these cases I use the injection as *hot as it can possibly be borne*—three or four times in twenty-four hours; at least two quarts should be used at each time.

"2. In cases of ten days' or two weeks' duration (at which time the inflammatory process has ended), I believe the most of the trouble can be relieved in a very few days. The suffering so characteristic of that stage will usually pass away in twenty-four hours. In many of these cases I have been enabled to force the water into the bladder, and then allow the patient to pass it away immediately. This has a good effect upon the dysuria, relieving it almost at once. In this class of cases, also, the water should be very hot.

"3. When two or three days have elapsed before the patient is seen, I do not expect so much as in the former classes. Even here much may be done by the external use of very hot water and the careful, gentle use of the fountain-syringe, filled with *simple warm water*, at about the temperature of the body, or less. This promotes cleanliness, and is a sedative.

"I would add that my three years' experience fully justifies me in commending this plan to the attention of the profession."

Two New Cardiac Poisons.

The *N. Y. Med. Jour.*, April 5, 1884, says:

Woorari seems in danger of being outdone as a cardiac poison, if we may judge from the accounts lately given before the Paris *Société de Biologie* of

two new Oriental arrow-poisons. A specimen of one of these poisons was presented by M. Rochefontaine, as we learn from a report of the meeting published in the *Progrès Médical*. It was said of this poison that an animal of medium size, wounded with an arrow the point of which had been imbued with it, would make one bound, and then fall dead; and that even an elephant would succumb after running no more than a kilometre. The composition of the poison is not known, being kept a dead secret by the Mois, from whom it was only by subterfuge that the specimen shown at the meeting was obtained. Taken into the stomach, the substance is said to be innocuous. One milligramme injected under the skin of a frog produced death within ten minutes, the heart being arrested in systole, and the reflexes persisting for a time. One of the speakers gave it as his opinion that the poison was probably obtained from the *Upas antiar*.

The other substance, shown by M. Laborde, was termed elephant poison (*poison d'éléphant*), and came from Borneo, where the inhabitants employ it for poisoning their arrows. Experiments on dogs have shown that this substance also kills by arresting the heart's action, but whether in systole or in diastole we are not told.

Two new poisons, then, are before the profession for investigation, and this will have to be directed both to their constitution and their physiological actions. But it must be confessed that the prospect of any notable advantage accruing to therapeutics from such research is remote, while the difficulty of obtaining the substance first mentioned stands in the way of the extended series of experiments necessary before precise conclusions can be arrived at.

The Correction of Deformities by Modifications of the Thickness of the Sole of the Shoe.

Before the New York County Med. Ass. (*Med. News*, April 5, 1884), Dr. William Detmold made some remarks, illustrated by diagrams on the blackboard, on the correction of certain deformities in the young by the simple device of thickening the inside or the outside edge of the sole of the shoe, as required. In weak ankles, which were exceedingly common among girls, owing to the breadth of the pelvis, which gave a tendency towards knock-knee, there was always a protrusion of the internal malleolus. This was ordinarily treated by placing a certain amount of stiffening on the inner side of the shoe, and, this failing, by the use of iron splints. The simplest and best way of correcting the deformity, however, was by

making the inner side of the sole thicker than the outer, which had the effect of lifting the weight off of that portion of the skeleton. The same method answered for the correction of knock-knee, but when the child was bow-legged, the thickening was to be placed on the outer instead of the inner side of the sole. If one leg was shorter than the other, there would inevitably result more or less tilting of the pelvis; which had the effect in time of producing lateral curvature of the spine, with its secondary or compensating curvature. This could easily be remedied, when taken in time, by making the sole of the shoe for the foot of the shorter limb sufficiently thick to bring the transverse axis of the pelvis at right-angles to the lower extremities. Dr. Detmold also explained his method of treating flat-foot (which was common in young girls who were poorly nourished and who were obliged to remain in a standing position much of the time), as well as elevation of one shoulder above the other. In five out of every nine young girls, he thought, the right shoulder was a little higher than the left.

Malignant Pustule.

Though comparatively rare, yet this is a most formidable disease, and we should be always ready to energetically combat it. Dr. Wm. S. Janney recently reported some cases before the Philadelphia County Medical Society, and now Dr. A. C. Griffin publishes a case in the *N. Y. Med. Jour.*, April 12, 1884. It was clearly traced to the bite of a fly received in a restaurant.

On making inquiries about the restaurant, it was found that the employees had been in the habit of throwing waste scraps of meat and other refuse into a back yard. This practice having been complained of, it was stopped, by an order from the Board of Health, and for several days afterward the flies swarmed about the restaurant, annoying all by their savageness. So far as could be learned, this was the only person of those exposed whose physical state was in a condition susceptible to the inoculation of septic material, which was undoubtedly conveyed to the blood of this patient by the bite. The fly, which was a common green-bottle or carrion fly, was killed on his cheek by a friend who was dining with him. The fly had bitten sufficiently to draw blood, and it was from this point as a focus that the malignant pustule began its career. That it was a malignant pustule the clinical evidence fully bore out.

He believes that the proper treatment in cases

of septic inoculation or malignant pustule lies in the prompt and thorough excision or cauterization of the point of inoculation, endeavoring by these means to prevent the growth and proliferation of the morbid elements, and thus check the absorption of those materials which would contaminate the whole system.

As for general treatment, stimulation should be carried to its fullest extent, and the best of the stimulants will be found to be alcohol. Quinine should be given in large doses to obtain its antipyretic as well as its antiseptic effects. Opium should be administered in quantities sufficient to quiet pain and allay nervousness. The bowels should be kept open by laxatives or mild cathartics. Poultices also seem to give some relief, especially when to them is added some sedative, as tincture of opium.

The Treatment of Scalp Wounds.

In view of the danger of causing erysipelas, inflammation, or suppuration, when the ordinary sutures are used for scalp wounds, we hail with pleasure the suggestion made by a correspondent of the *Lancet* (April 5, 1884), which, while not very new, is yet worthy of repetition:

The scalp is remarkable for the looseness with which it is attached to the subjacent bone, and in simple cuts through the scalp blood and serum can readily force a way between the scalp and the bone, and the accumulation induce suppuration. Still more frequently the scalp is torn away from the skull in a longer or shorter flap, and then, if the edges of the wound are united, the serum effused from the under surface of the detached flap is confined beneath it, and suppuration occurs. If this fact be neglected, suturing scalp wounds is a dangerous step; but if it be recognized and acted upon, the sutures are altogether devoid of danger. The main thing in the treatment of any flap scalp wound, however slight the flap may be, is to secure primary adhesion of the flap to the subjacent pericranium and completely prevent accumulation of serum beneath it. This must be secured by properly-adjusted pressure; and, in view of this primary indication, but secondary importance should be attached to the rapid healing of the edges of the wound. If a good bunch of hair be taken up on each side of the wound, and twisted, and then used as a suture, it is obvious that the whole surface of the scalp from which the hair springs is held compressed against the subjacent skull; and hence this form of suture skillfully employed really fulfils the indications of treatment very well. It is an error to suppose that the tissue of

the scalp is more intolerant of the presence of a suture than the skin of any other part of the body.

The Incubation of Measles.

Dr. Blenkarne thus writes to the *Brit. Med. Jour.*, April 5, 1884:

Six or seven months ago, J. H., aged about twenty, residing in a neighboring village, where there was not at the time (nor had been for a long time previously) a single case of measles, traveled by train to Brackley, a distance of about eight miles. On looking around the carriage, she found among her fellow-passengers a woman with some children—one, an infant in arms, which had a very red face. On getting into conversation with the mother, she discovered, to her horror (being of somewhat nervous temperament), that the said infant "had 'fell' with the measles" (*alias*, the rash had come out) at Bletchley Junction, *i. e.*, about half an hour before my patient entered the carriage—the other children having recently recovered from the same disorder. Just a fortnight afterwards J. H. returned home, feeling on that day "out of sorts," with coryza, and sent for me the following morning, when I found her with the rash well out all over her face, neck, and shoulders. The complaint ran a mild course. A fortnight exactly after this, her youngest sister (who had not seen her for some time until her return home) caught the infection; the general feeling of *malaise*, etc., occurring on one day, and coming out very freely the day following. In this second case the complaint also ran a mild course, and no other case has occurred in the village up to the present date (March, 1884).

Syphilis and Locomotor Ataxia.

Dr. Leonard Weber thus concludes a paper in the *Med. Record*, April 5, 1884:

First.—There is not sufficient evidence to show that syphilis may be the direct cause of the typical form of locomotor ataxia, *i. e.*, posterior sclerosis of the cord.

Second.—There is proof, and plenty of it, that syphilis produces certain lesions in the cord and its meninges as readily, if not as frequently, as in the brain. These lesions may be, and often are, followed by symptoms of (atypical) tabes. They are generally relieved by prompt and energetic specific treatment, but rarely cured.

Third.—Experience has shown me that the tendency of the syphilitic virus to produce lesions in the nerve-centres occurs the sooner, the less its action is interfered with by judicious and pro-

longed treatment, although old cases of syphilis are, *ceteris paribus*, more apt to develop symptoms of neurosis than those of more recent date.

Fourth.—As it has been shown by all observers that syphilitic lesions of the central nervous system once established are seldom really cured by specific remedies, we have additional reason to insist upon timely and long-continued treatment. It is also our duty to impart such information of the nature of the disease to the patient as will lead him to keep a strict and judicious watch over himself, and have suspicious symptoms attended to as early as possible.

Fifth.—I believe a properly graded inunction-cure with unguentum hydrargyri in most cases of syphilis to be the best means of reducing the disease to early and harmless latency.

Traumatic Rupture of the Trachea.

To the New York Surgical Society (March 11, 1884), Dr. J. L. Little presented a trachea removed from a man sixty years of age who died in St. Vincent's Hospital, having been struck in the neck and upper part of the sternum by one of the shafts of a truck. When he first saw the case, five hours after the injury, he found the patient emphysematous from the head to the lower part of the abdomen. There was considerable ecchymosis over the sternum. No difficulty in breathing. No cough or pain on pressure over the upper part of the sternum and trachea. Had had slight expectoration of blood before entering the hospital. The emphysema was greater over the chest than elsewhere, and less about the neck. Injury of the trachea was suspected. The patient was anesthetized, and a careful examination was made over the trachea and larynx. But no injury of these parts could be detected, and, as there were no symptoms of suffocation, it was thought best not to perform tracheotomy. He, however, gradually sank, and died this morning, sixty hours after the injury. There was considerable cyanosis during the last twelve hours, but no symptoms of suffocation.

The autopsy showed a complete separation of the fourth and fifth rings of the trachea, with signs of recent inflammation and hemorrhage in the surrounding tissues. Double hypostatic pneumonia and pleurisy also existed.

Congenital Absence of Femur.

To the Pathological Society of London (March 18, 1884), Mr. Roger Williams showed photographs of a boy, in whom the femora were absent. No trace of the femur or patella could be found on

careful examination on either side; a bony mass in the groin, and apparently articulating with the pelvis, was ascertained to be the head of the tibia somewhat altered. Mr. John Wood said that about twenty years ago, a man who went by the name of the man-monkey was well known in London; the femora were absent, but he was exceedingly agile, and this, combined with the fact that his hands reached to the ground, had earned him his soubriquet. He thought that one moral might be drawn from such cases, and that was how exceedingly useful one section of a limb might be; it was, he thought, an argument in favor of the operation of excision.

SPECIAL REPORT.

OPHTHALMOLOGY.—NO. XVII.

BY C. S. TURNBULL, M. D.,

Oculist to the German Hospital, Philadelphia.

Transactions of the American Ophthalmological Society.

Nineteenth Annual Meeting, Catskill Mountains, 1883. Published by the Society.

Thirty-eight members were present. Dr. H. D. Noyes, of New York, was elected President, and Dr. W. F. Norris, of Philadelphia, Vice President, and the Society adjourned to meet at the Catskill Mountains, July, 1884.

Twenty-seven papers were presented, as follows, and the amount of interesting material presented serves but to illustrate the interest and energy of this body of working specialists.

Dr. H. Derby, of New York, presented a paper on the "*Influence on the Refraction of Four Years of College Life.*"

So far as his figures go, they tend to show, first, the large amount of myopia, even in this country, among the educated classes. Dr. Loring's combined table of observations, made on the eyes of scholars up to the age of 21, in various countries, gives the German percentage of myopia as 62.10, the Russians 42.8, and the American 26.79. Derby's investigations gave him, among 443 freshmen at Harvard, and Amherst, a myopic percentage of 34; at graduation at Amherst, a percentage of 47.2. It is difficult, however, says D., to compare Dr. Loring's figures with my own, as his statistics were based on observations made between the ages of 6 and 21, and mine between 18 and 23. But all researches made at this latter age go to prove that, at least, or very nearly, one-half of the educated community is myopic, in this as well as other countries.

Moreover, contrary to the impression so long

entertained, myopia may be acquired at, or near, the twentieth year, from the same causes that produce it at an earlier age, and may continue to progress until the course of study is completed.

2. "*Some Improvements in Instruments and Appliances for Cataract Operations.*" By Russell Murdoch, M. D., of Baltimore.

3. "*A Case of Tubercle of the Iris.*" By H. S. Schell, M. D., of Philadelphia.

"The patient, a schoolboy, nine years of age, applied for treatment at Wills' Eye Hospital on August 29, 1881. The eye had been painful for four days, and exhibited the usual signs of ordinary plastic iritis. Treatment was of no avail, and on the following October he was admitted to the Children's Hospital, suffering from well-marked symptoms of coxalgia in the second stage. There was a distinct history of phthisis on the mother's side. The eye was still somewhat painful. There was a ring of circumcorneal injection, the pupil was immovable, the fibres of the iris atrophied, and projecting from the nasal side of the pupillary margin was a small yellowish-white nodule, the size of a pin's head, and tinged with pink. This nodule gradually increased in size. Vision was completely lost in December, and in May, 1882, the anterior chamber was nearly filled with the new growth. The nodule was of a yellowish tinge, and a few minute blood-vessels could be seen upon its surface. At this time the intra-ocular tension was increased, and the eye was tender on pressure, but not otherwise painful. (An accompanying colored lithograph represented the external appearances quite accurately.) In the meantime an abscess had formed on the outer side of the thigh. It was aspirated by Dr. Ashhurst, and twenty-four ounces of pus withdrawn. The abscess rapidly refilled, and opened spontaneously at the point of puncture a week later. A diagnosis of tubercle of the iris was made, and on May 30th I enucleated the eye, with the hope of preventing the extension of the disease. Healing progressed without obvious incident. The discharge from the thigh gradually decreased, ceased in July, and the boy was discharged from the hospital in September with very good movement of the hip, and but slight shortening. The excised eye was placed in Müller's fluid, and a microscopic section subsequently examined by Dr. Geo. B. Laurason, of New Orleans. He reports that the specimen shows two or three tubercular masses imbedded in a mass of organized inflammatory product. There is one small round tubercle in the left ciliary region, and in front of the iris an oblong tubercular mass is seen,

containing three or four plugged-up blood vessels. The tubercles seem to have developed in the organized inflammatory product, which nearly fills the anterior and posterior chambers."

4. Also, *A Case of Tuberculosis of the Ciliary Body and Iris*. By O. F. Wadsworth, M. D., Boston. Child aged three and a half, was sent to me by Dr. H. Derby for consultation, on October 24th, 1882. Dr. Derby wrote: "I first saw this eye October 4th. The process had then lasted two weeks. It seemed to be a kerato-iritis, as well as I could make out. The question was as to glioma or irido-choroiditis. The father stated that both he and the mother were in good health; and there were two children older and two younger than this one, the oldest seven years, all well. 'Never a doctor in the house with any of them.' These statements as to the health of the family were found later to be quite incorrect. I found, as had Dr. Derby, that it was very difficult to obtain a view of the eye. Even when the patient was held and the lids forcibly opened, the rolling up of the eye and the great flow of tears prevented a satisfactory inspection. The lids were natural; the cornea hazy; the conjunctiva of the bulb moderately congested, but no very marked ciliary congestion; the anterior chamber of good depth; pupil moderately dilated; the upper portion of the iris apparently thickly set with vessels; a yellowish reflex from the pupil. My diagnosis wavered between glioma and irido-choroiditis, as I suggested to Dr. Derby the advisability of an examination under ether before advising enucleation. Both Dr. Derby and I believed the growth to be a glioma. The eye was enucleated the same day by Dr. Derby, placed in Müller's fluid, and given to me for examination. Microscopic examination showed the greater part of the solid mass to be mainly made up of granulation tissue, varying in different parts, here containing closely-packed small cells, there mostly consisting of fibres running approximately parallel—the latter most numerous at and near the anterior border, and now and again broad bundles of the fibres curved forward to the posterior surface of the cornea. Through the mass ran large vessels, and there were remains of many hemorrhages. The pigment, irregularly scattered, was for the most part all that could be made out as remainder of the normal tissues of iris or ciliary body. Throughout this tissue, except in the more fibrous portions, were scattered rounded agglomerations of cells, more deeply stained by hæmatoxylin, and showing the characteristic cell-forms and arrangement of tubercle; giant cells containing many nuclei, surrounded by epithelioid and

small granulation cells. The posterior layer of the mass was much more free from cells, and appeared to consist of the infiltrated and thickened remains of the vitreous. In this was seen also, in the sections, the collapsed and folded lens capsule, lined here and there for a short distance by what seemed to be its degenerated epithelium, and containing apparently some debris of lens fibres. One-half of the globe was given to Dr. H. C. Ernst, then engaged in the investigation of the bacillus of Koch, and although the fact that the eye had been in Müller's fluid made the search more difficult, he was able to demonstrate satisfactorily the presence of the bacillus in the specimen. Until the result of the microscopic examination was reached, there had been no suspicion of the tuberculous nature of the disease. This was the first case of the kind either Dr. Derby or I had seen, and the family history, as given by the parents, gave no indication that such disease was at all likely. Indeed, looking back now, with the knowledge of the true nature of the case before me, I am unable to recognize anything in the visible appearances of the growth when I saw it, or in the history of its course, by which it could be distinguished from a glioma, unless, perhaps, the great vascularity of the iris which preceded the development of the growth into the anterior chamber may be regarded as of some value for the differential diagnosis.

The statement that the child herself and the whole family had been free from anything pointing to tubercle, made the case one of much interest to follow. The child continued in apparently good health for more than five months after the enucleation; then for five or six weeks she complained of headache, not enough to lead the parents to call a physician; suddenly became worse, and Dr. Ferguson, who was called, found her in convulsions. She died three days later, with the diagnosis by Dr. Ferguson of tubercular meningitis. There was no autopsy. It was only some time after her death that I learned from Dr. Ferguson that he had attended the family for several years, that the child's father and brother of the father had phthisis, and that the children had been subject to bronchial attacks."

5. *A Personal Experience with Prismatic Glasses*. By S. F. McFarland, M. D., Oxford, N. Y., who says: "Opinions are so various in regard to the efficiency of prismatic glasses in correcting or alleviating the distressing annoyances resulting from muscular pareses, that he gives a brief statement of long personal experience in the use of them." (Pareses of the ocular muscles are, as a rule, too

carelessly noticed, and carefully-adjusted prisms prove a boon to many an aching head. Especially is this the case in near-sighted people. In such, the centering of the glasses is everything as regards the comfort and ease of fit, and opticians cannot be too carefully watched in the adjusting of frames. There should really be a special de-centering as carefully ordered as the glasses the oculist may prescribe, because of the frequent occurrence of pareses, as well as peculiar conformation of the orbits.)

6. *On the Apparent Curvature of Surface Produced by Prisms.* By O. F. Wadsworth, Boston.

7. *A Case of Sympathetic Neuro-retinitis.* By James A. Spalding, M. D., Portland, Me.—“the peculiar point of interest being that contrary to the opinion expressed by Mauthner, who ‘would not like to enucleate in a case of sympathetic neuro-retinitis,’ the right eye was enucleated to relieve the pain from which the patient was suffering. The operation was followed by excessive hemorrhage, which could not be checked by pressure or hot water, and only ceased after ligature of one artery deep in the orbit, and of a second which appeared to spring from the band of connective-tissue uniting the globe and upper eyelid. The case now proceeded favorably, and the patient was sent home in ten days with the vacant orbit in a promising condition. Owing to my desire to see what influence the enucleation of its fellow would have upon the better eye, I abstained from all medical treatment. The result appeared to justify my opinion of the truly sympathetic nature of the neuro-retinitis, for sight gradually returned to the remaining eye. The pain in the head disappeared with considerable rapidity.

“Three months later, he saw the patient again, and examined her with the ophthalmoscope. Left eye normal, pupil active, media transparent, retina and optic papilla normal; the only abnormality consists in the presence of slight tortuosity of the same vein, which was previously mentioned as projecting into the vitreous. Vision $\frac{2}{30}$ and Snellen $1\frac{1}{2}$ with ease, with convex 16 (2, 5, D.).”

8. *Report of Thirty-five Cases of Cataract Extraction.* By David Webster, M. D., New York.

9. *Notes on Ocular Therapeutics.* By W. W. Seely, M. D., Cincinnati, O.

“The first point I desire to notice is in the use of the yellow oxide of mercury in external ocular troubles. Probably every one has found the use of this remedy, whether in corneal or conjunctival diseases, like calomel in the past, often attended with pain. This often-recurring fact and

disadvantage led me some time ago to institute some investigations in regard to the cause or causes.

“So far as regards the strength of the preparation, I have found that ten grains to the ounce of the vehicle is the best for all purposes. When I began to inquire into the mode of action of the yellow oxide, I found that this preparation was regarded chemically as an insoluble substance. My theory in regard to its action at first was, copying from the supposed action of calomel, that a chemical change occurred; but finding that it was an insoluble substance, and hence inert, this explanation seemed to fail.

“I took a large number of specimens and had them analyzed, and found that all the so-called ‘chemically pure’ preparations contained more or less bichloride, and the inference from this was that its action depended on this residuum in its manufacture.

“My assistant, Dr. Caldwell, has lately been working at the subject, and is satisfied that there is a certain amount of solubility in the yellow oxide, to what degree tests have not decided.

“One point seems settled—that the less bichloride a preparation contains, the less the pain produced by the salve, efficiency remaining the same.

“I desire to add one more practical point in the use of the yellow oxide and vaseline, as devised by myself some years ago, in conjunctival affections. Those who have used this combination have doubtless found that in cases where there is a profusion of tears the salve is so quickly washed out that little or no benefit results. In such cases I substitute eserine or the bichloride in solution to contract the blood-vessels. The strength of the bichloride solution that seems to answer every purpose, is one part to seven or eight thousand (one grain to sixteen ounces water), or about one-third the strength preventive of the growth of the bacteria of ordinary decomposition.

“Such a solution, entirely painless, has often, in my hands, set aside an acute catarrhal conjunctivitis of violent type, after one to three or four thorough drenchings of the conjunctiva.

“This is the strength I have used for a long time as an antiseptic in various operations.

“I merely state this to introduce a point I regard of great practical importance. In my hands, one thorough application of a four-grain solution once a day acts altogether better than more frequent applications, either of the same solution, or of weaker ones. This remark applies to all classes of cases.

“One point more in regard to eserine. For the

reduction of intra-ocular tension, eserine has for me entirely done away with paracentesis, and for so long a time and so completely that this procedure has really only an historical interest."

(To be Continued.)

CORRESPONDENCE.

On Blood-letting as a Specialty.

EDS. MED. AND SURG. REPORTER:—

I have been reading Dr. Corson's recent articles in your journal in regard to blood-letting in the young and old, and in that connection I have referred to some old files of the REPORTER, as I frequently do, and I noticed several well-written articles on the subject of blood letting in pneumonia, but none that seemed to me to be of so much practical importance, or so little tinged with self-laudation, as the one from the pen of Dr. W. G. Bronson, of New Canaan, Conn.

The communication from Dr. Bronson has the true ring, certainly; and I have no doubt it met with a hearty amen from those of the profession who are not wedded to hobbies of their own. I have always read everything from the pen of Dr. Corson with interest, for he writes vigorously and well, and his half century and more of practice is more than the vast majority of physicians attain to.

I well remember his communication some years ago in regard to the ice treatment in scarlet fever; then a few years later one on the use of the forceps in labor; then followed an article on the use of the lancet in pneumonia, with the one above mentioned on bleeding in the young and old.

Being young in the profession when the first article appeared, I eagerly imbibed the idea there set forth, that no child would or could die with scarlet fever when ice was used. I felt myself able to cope with the dread disease in any form. But alas! how many times since have I seen the darlings of many a family ruthlessly cut down, in spite of ice and everything else that could be tried. If Dr. Corson has ever passed through an epidemic of scarlet fever such as I have several times—and he certainly has—he must have seen times when the hand of death was upon the little sufferer from the very first moment; when ice nor veratrum, nor quinine nor stimulants, delayed for the briefest period the monster.

How idle and ridiculous it seems, then, for any one, even with Dr. Corson's experience, to claim that any particular treatment will cure every case. Since I have been a subscriber to your journal, a great many specifics have been proclaimed by different parties for diphtheria, but when tried on a malignant case, had no effect at all. I have recently had several cases of pneumonia, one of which was a regular "typical case," such as is mentioned by Dr. Corson, in his communication several years ago. But, strange as it may seem, although the patient presented the identical symptoms mentioned by Dr. C., I did not bleed, for I did not consider it necessary. Blisters, opiates, veratrum—which Dr. C. con-

demns so much—stimulants and good food, brought the patient around nicely, along with other "typical cases" under same plan of treatment.

Do not understand me as condemning the lancet. Far from it. It should be used like any other powerful remedy—whenever it is necessary—but only when, in the opinion of a fair-minded physician, it is the best thing to do. I am opposed to indiscriminate bleeding by inexperienced persons.

A young practitioner, reading Dr. Corson's communication, would think nothing more was required than a good bleeding; and failing to diagnose correctly, would use the lancet without judgment, or reason, or necessity. Dr. Bronson well says, that the gravity of pneumonia depends, largely, on its character, age, etc., and that a great many will recover without any treatment. We all know that to be true; and we know equally well that some will die, no matter how much they are bled, as Dr. B.'s two cases did; and it would seem hardly possible for Dr. Corson not to have lost some of his patients, even after he had taken a pint or so of blood from them, although he does not mention any such loss. However, when I began this communication, I intended to say something about bleeding in the young and old, *in re* Dr. Corson's recent articles on those subjects.

It is barely possible that in certain conditions of new-born children, bleeding would be called for; but, in a practice of twenty years, I can not think of a single instance in which I have the slightest idea that a child could have been saved by that means. Suppose, taking any one of Dr. C.'s "typical cases," in which he considered blood-letting necessary, he would have plunged the child into a warm bath, with other appropriate and suggestive treatment, would not the result have proven just as satisfactory? What possible benefit can be derived from taking blood from a child, with any and every infantile ailment, as Dr. C. evidently teaches, is more than I can understand. There are cases, certainly, when it would be beneficial; but since the wisest of our profession do not pretend to be able, at all times, to tell what ails a child, how are we to know when to bleed? Indiscriminate bleeding here would surely be more reprehensible than in adults.

In all the cases presented by Dr. C., after a careful reading, I can find nothing in the result to advocate the utility of it. Notably in the case of stramonium poisoning, while virtually admitting that it did no good, he says it did no harm. That seems to be begging the question, it is the *good* he is after, else where is the necessity of bleeding at all?

Dr. C. has a long article on blood-letting in the old, and presents quite a number of "typical cases." When you read of one, you have a sample of the whole—some, of course, being spare and thin, others stout, all feeling about the same way—dull, languid, headache, etc. I except, of course, any who may have presented apoplectic symptoms, in which case bleeding is always eminently proper. All these old people had been in the habit, doubtless, of being bled every spring, most likely some of them in the fall too, and blood-letting was the sovereign balm for all their ills. Allow me to say right here, that in the good old days of blood-letting in the community in

which I practice, here and there an old man in the country had his lancet, and all the old folks got bled spring and fall as regularly and punctually as they sheared their sheep or pulled their beans. I can, at random, select any old person, and ten to one, if he or she is over sixty years of age, there will be so many cicatrices in the region of the median cephalic vein that an experienced bleeder like Dr. C. could hardly find a place for his lancet. My father and mother were both believers in, and practitioners of, this useless habit; and I well remember how frequently, in my younger days, the lancet would be called into requisition, sometimes by an old doctor in the neighborhood, but oftener by any old farmer who happened to have a good one. My mother's arms, at the bend of the elbow, were both actually so cut and hacked by the lancet that I think it would have been impossible to bleed her from either arm. My father's were not quite so bad. Both have requested me frequently to bleed them; but they managed to live comfortably for twenty years at least without their customary loss of blood, and both died a year or so ago, the one long past four score, the other nearly that. There are plenty of old people in this neighborhood who are past four score, and who have not been bled for twenty years, and they sensibly conclude they don't need to be.

Returning to Dr. C.'s cases, we will take the case of the old lady ninety-one years old, in her second childhood. Suppose the doctor had given her a *placebo*, if such a term could be applied to blood-letting, that is, bled her to about ten drops, instead of as many ounces, and made her believe it was a good deal—will he say it would not have done as well? She no more needed to be bled to any extent—than she needed the latest fashionable bonnet. The fact he mentions in regard to the ages of some parties who were bled, argues nothing in favor of blood-letting, but rather in favor of the superior sanitary and dietetic regulations of to-day, as compared with fifty years ago. People live longer in every community to-day than they did fifty years ago. Men were considered very old who reached sixty-five or seventy; now such ages, and much greater, are common. I hope those good old remedies, the lancet, opium, and calomel, will never go out of fashion. There are times and diseases in which they, or some one of them, are our sheet-anchors; but because this is so, is it any reason why they should be used in season and out of season? And are we to learn nothing as we go along? Is our science to make no progress corresponding with everything else? There are medicines in use to-day which were never thought of when Dr. C. commenced to practice, and which we could hardly do without; but while this is so, we need not entirely discard our old friends. We can use them when necessary. Opium has not, and never can have, a substitute, and the same can be said of calomel and the lancet; only let us not abuse the use of any of them, any more than we would or should any of our later remedies. To argue that blood-letting is the only remedy in every case, is to argue against light and knowledge, notwithstanding the able advocates of the practice in the person of Dr. Corson and others. WM. F. MITCHELL, M. D.

Addison, Pa., April 7, 1884.

NEWS AND MISCELLANY.

American Climatological Association.

The programme of exercises at the first annual Congress of the American Climatological Association, to be held at the Hall, northwest corner of Sixth and F streets, Washington, D. C., on May 3d and 5th, 1884, (sessions 10 a. m. and 3 p. m.) is announced as follows:

Papers: 1. Opening address, F. I. Knight, M. D., Boston, Mass. 2. "The Etiology of Pulmonary Phthisis," B. F. Westbrook, M. D., Brooklyn, N. Y. 3. "Dryness and Elevation the Most Important Elements in Climatic Treatment of Phthisis," Chas. Denison, M. D., Denver, Col. 4. "Some Observations on the Diagnosis of Pulmonary Diseases," D. N. Kinsman, M. D., Columbus, Ohio. 5. "The Effects of Humidity on the Cause and Course of Diseases," W. H. Geddings, M. D., Aiken, S. C. 6. "The Effects of Sea Air on Diseases of the Respiratory Organs," Boardman Reed, M. D., Atlantic City, N. J. 7. "The Use of Compressed and Rarefied Air, as a Substitute for Change of Climate, in the Treatment of Pulmonary Diseases," J. Solis Cohen, M. D., Philadelphia, Pa. 8. "The Constituents of Climate and Their Relation to Disease," J. Hilgard Tyndale, M. D., New York. 9. "The Relation of Laryngeal to Pulmonary Diseases," F. H. Bosworth, M. D., New York. 10. "The Climate of Large Cities Dangerous to Consumptives," Frank Donaldson, M. D., Baltimore, Md.

The above is a list of the papers already reported to the Committee. Others have been promised, but the titles have not been sent in. The order of reading will be arranged at the time of the meeting.

A New Surface Thermometer.

At a recent meeting of the Société Médicale des Hôpitaux, M. Paul exhibited a new form of surface thermometer of simple construction. The instrument consists of a straight stem and a spiral coil, which are connected to one another by a short junction at right angles to the direction of the straight stem. This essential part of the thermometer is enclosed in a covering of caoutchouc, which has the shape of a shallow hat or cupping-glass. In communication with the internal cavity of the hat is a hollow tube, provided with an elastic pear-shaped bag. When the latter is emptied by being squeezed, the open, somewhat funnel-shaped end of the hat is applied to the skin, and on relaxing the pressure on the elastic bag, the instrument becomes affixed by the atmospheric pressure.

American Surgical Association.

In our next issue we will give a report of the proceedings of the American Surgical Association, which met in Washington, April 30, May 1, 2, 3.

The American Medical Association.

The Pennsylvania Railroad Company has fixed the rate of fare for delegates at \$9.80 from New York to Washington and return, \$6.10 from Philadelphia to Washington and return, and \$1.65

from Baltimore to Washington and return. Limited round-trip tickets can be obtained, for these prices, at any of the offices of the road, on presentation of credentials.

Items.

—It is said that the recent flood has improved the health of Cincinnati by cleansing the unhealthy districts.

—Prof. A. Vercelli performed nephrectomy, in Milan, on March 10, for carcinoma of the kidney. The patient died in five hours.

—A case of chromidrosis (rose color) was shown by M. le Roy de Méricourt at the meeting of the Académie de Médecine on March 25.

—The New York State Assembly has passed a bill prohibiting the sale of drugs by any other persons than pharmacists and physicians.

—Prof. Alfred Stillé, after twenty years' service as a teacher, delivered his valedictory address to his class on April 10, his resignation, as announced at the beginning of the term, taking effect at the close of the session.

—Dr. H. H. Seelye, who recently completed his term of service on the house staff of Bellevue Hospital, has been appointed instructor in physical education at Amherst College, succeeding Dr. Hitchcock, who goes to Cornell University.

—Dr. Robert Wright, the oldest graduate of West Point, died at Centreville, Md., April 21, aged eighty. The doctor had served his country faithfully for many years, and had held many positions of public trust in Maryland, his native State.

—The bill defining the titles and duties of army medical officers of the higher ranks has passed the Senate. Surgeons with the rank of Colonel are to be styled Assistant Surgeons-General, and those with the rank of Lieutenant-Colonel, Deputy Surgeons-General.

—The French Government is reported to be preparing a system of quarantine and inspection of vessels arriving from infected ports, in view, it is said, of the present prevalence of the disease in India. A London dispatch dated April 23 reports the arrival of an English ship at Alexandria, Egypt, from India, with a case of cholera on board.

OBITUARY NOTICE.

DR. WILLARD PARKER,

The distinguished New York physician, whose health has been gradually failing for the past six months, died April 25. Dr. Parker was 83 years old, and had been a practicing physician over fifty years. He was born in Hillsboro, N. H., on the 2d of September, 1800, his ancestors on both sides being English Puritans, who came to Massachusetts in 1640, and settled at Chelmsford. They were active farmers, and more than one member of the family became distinguished in the revolutionary war. Willard Parker was a farmer's boy, working from sunrise until sunset on his father's possessions. At 19 he had fitted himself as a teacher, and, by diligent study, prepared himself for Harvard College, where he was graduated in 1826.

He then began the study of medicine in the city of Boston, and later he went to Woodstock, Vt. In 1830 he was appointed to the chair of anatomy in the Berkshire College, at Pittsfield, Mass. In 1836 he accepted the chair of surgery in the medical college at Cincinnati. Soon afterward he went abroad, and spent some time in the French and English hospitals. Ill health forced him to leave the West on his return, and he was appointed to the chair of surgery in the College of Physicians and Surgeons in New York city. His life since then has been one of peculiar devotion to the interest of his profession.

In 1856 he was appointed visiting surgeon to the New York Hospital. In 1865, on the death of Dr. Valentine Mott, who was then President of the New York State Inebriate Asylum, at Binghamton, Dr. Parker was appointed his successor. In 1870 Dr. Parker resigned the active duties of his professorship of surgery in the College of Physicians and Surgeons, becoming Emeritus Professor of Surgery. In the same year he received the degree of LL. D. from the College of New Jersey at Princeton. He was consulting surgeon to the New York, Bellevue, St. Luke's, Roosevelt, and Mount Sinai Hospitals, and the Home for the Ruptured and Crippled. He was a member of the New York Medical Society, American Medical Association, the New York County Medical Society, the Academy of Medicine, the Pathological Society, the New York Medical and Surgical Society, and the Society for the Relief of the Widows and Orphans of Medical Men. He was an honorary member of many other societies.

QUERIES AND REPLIES.

EDS. MED. AND SURG. REP.—

I would like to ask, through the REPORTER, what the most successful treatment is for pruritus ani? Also for the treatment of oxyuris vermicularis? I hope to hear of something that will be better than anything I have found as yet for the treatment. E. R. S.

Metz, Ind., April 7, 1884.

MARRIAGES.

BULLARD—HUPP.—At the First Presbyterian Church, Wheeling, W. Va., Wednesday afternoon, April 23, 1884, at three o'clock, by the Rev. Dr. Cunningham, Dr. R. H. Bullard and Miss Annie L. Hupp, daughter of Dr. John C. Hupp. No cards.

LYLE—ALEXANDER.—At the home of the bride's mother, in Bellevue, Pa., Wednesday evening, April 9, 1884, by the Rev. T. R. Alexander, Dr. John W. Lyle, of Washington county, Pa., and Ada E. Alexander, of Bellevue.

SWIFT—GRIFFITHS.—At St. Paul's Church, Des Moines, Iowa, Wednesday, April 16, 1884, by the Rev. W. H. Van Antwerp, Lawrence Chew Swift, M. D., formerly of New Brunswick, N. J., and Miss Mabel Bruce Griffiths, daughter of Colonel Joseph M. Griffiths, of Des Moines, Iowa.

DEATHS.

CUYLER.—At his late residence in Morristown, N. J., on Saturday evening, April 26, 1884, Dr. J. M. Cuyler, Brigadier-General in the United States Army.

PARKER.—At his residence, in New York city, Friday, April 25, 1884, Dr. Willard Parker, in the eighty-fourth year of his age.

WEATHERBY.—In this city, April 20, 1884, Joseph C. Weatherby, M. D., in the seventy-second year of his age.

THREE CASES ILLUSTRATING SOME POINTS IN THE PATHOLOGY OF CERTAIN INJURIES OF THE SHOULDER- JOINT.*

BY C. B. NANCREDE, M. D.,

Surgeon to the Episcopal Hospital, and to St. Christopher's
Hospital for Children.

A few preliminary anatomical points must be passed in review for the ready comprehension of my later remarks. The shoulder-joint differs in many important points from any other articulation of the body. A moment's reflection upon the almost unlimited range of movement which it enjoys, will at once suggest that the ligaments of this articulation cannot be the means by which the joint-surfaces are held in apposition; otherwise, anything like freedom of movement would be impossible in a ball and socket-joint where the socket is so shallow as in this articulation. What then does hold, firmly apposed, the articular surfaces? It must be something always tightly stretched, yet always capable of lengthening, or rather always practically loose. Nothing but muscle could fulfil any such purpose. In truth, the muscles surrounding the joint are the most important ligaments the articulation possesses. When these are paralyzed, or in the cadaver, the head of the humerus readily falls away from the glenoid fossa. Bearing this fact in mind, you will clearly apprehend that the joint surfaces are kept pressed together solely by muscular ten-

sion. Again, the glenoid fossa, unlike the socket of any other important joint, *has no epiphysis*, which explains to a degree the fact that even in the young the head of the humerus may be so affected as to demand excision, while the glenoid process is either entirely or nearly healthy. Closely related with the scapulo-humeral joint, we find a number of bursæ, some of which commonly communicate with the joint, while others do not. To the former alone I shall devote my remarks. There is a large one between the acromial process and the coraco-acromial ligament upon the one hand, and the shoulder capsule upon the other. The bursæ—the exact sites are unimportant for our present purposes—are situated between the subscapularis muscle and the capsule. An occasional one is placed between the infraspinatus muscle and the capsule, into which it often opens, as do the others just mentioned. Let an inflammation be set up in these sacs, and it certainly spreads to the joint itself, should communications exist, or nearly as surely by mere contiguity of tissue, if no opening between joint and bursæ is present. The articulation is securely covered in by the voluminous deltoid, so that any direct injury to the fibrous or synovial tissues of the joint is almost impossible from direct force, as a blow, although a twist *may* injure it, notwithstanding the latter is more apt to tear the bursal walls. The upper epiphyses of the humerus—of which there are three—coalesce at five years; but they leave a layer of epiphyseal cartilage between head and tuberosities and shaft, which in places either coincides with the capsular attachment, or is actually within it. From these anatomical facts it must be clear that direct force,

* Read before the Philadelphia County Medical Society, March 20, 1884.

as a blow, can rarely injure the joint itself, but must either set up trouble in the surrounding bursæ, or in the epiphyseal cartilage, or in both. Once again, the interior of the joint, the muscles moving the joint, and the skin over their attachment, are all supplied by the same nerve or nerves; so that let a joint injury start where it may, the articulating surfaces of the shoulder-joint are subjected to such an injurious degree of pressure from direct or reflex muscular contraction as is possible for no other articulation. The bearing of these anatomical facts upon prognosis and treatment need hardly be pointed out.

The first specimen I proposed showing was presented to the society some years back, and my reason for again showing it is the sharply contrasted result presented by the second specimen which I shall exhibit.

On November 27, 1878, the society had an opportunity of examining the first patient and the admirable results of the case. To those who were not present, or who have forgotten the details, I will briefly recapitulate the history of the case, with the treatment pursued.

Compound Fracture of the Anatomical Neck of the Humerus.

"The patient, J. M., æt. 14 years, fell, upon the afternoon of September 23, 1878, from a tree about twenty-five feet, landing on the ground, but striking in his fall against the branches of the tree, and sustained the following injuries: The shaft of the humerus was separated from the head and greater and lesser tuberosities. The line of fracture closely followed the epiphyseal cartilage, although in several places the diaphysis was fractured. The shaft, slightly split, was driven through the integuments over the lower part of the deltoid muscle on its anterior aspect, tearing in its course the following parts: the insertion of the deltoid was completely stripped off with the subjacent periosteum; the coraco-brachial, teres major, and latissimus dorsi were in like manner torn off, the latter carrying with them the posterior lip of the bicipital groove. The tendon of the pectoralis major was torn off about half an inch from its insertion, and one, if not both heads of the biceps, was ruptured. In consequence the head and neck of the bone, deprived of periosteum, merely hung suspended by the capsular ligament and the rotator muscles. The shell of bone connected with the head and tuberosities was fissured at various portions of its circumference, as if by the impacting action of the wedge-shaped extremity of the shaft. I enlarged the wound and removed the fragments you see, viz.:

4½ inches of the humerus, including its head. Seven weeks after the operation he could remove his coat, vest, and shirt without assistance. Ten weeks after the injury considerable reproduction of bone, even up to the margin of the glenoid cavity, was observed, with new attachments for the pectoral and latissimus dorsi muscles, as determined by Dr. C. T. Hunter. The actual shortening consequently amounted to only 1½ inches. He had perfect use of the forearm, could put his hand to his mouth, behind his back, and to his ear. Of course he had lost all over-hand movements."

The course of treatment pursued, and my reasons for deciding upon it, seem worthy of detail, since such injuries are but seldom seen, and, as far as I can discover, no clear rules have been laid down for their treatment. To the members of this Society who devote themselves especially to surgery, I need hardly say that no question of amputation arose in my mind; but to those in pure medical practice I would say, that when the main vessels and nerves of a limb remain intact, the injury to the soft parts having been produced by the bone itself, not the fracturing force, almost any degree of shattering of the bones may be recovered from, in the young, without amputation. Two lines of treatment then offered for consideration, viz: the simple return of the bone, closure of the skin-wound, drainage, and trusting the case to nature; or the resection of the injured bone. Theoretically the first would have seemed the better course, promising no shortening of the limb, and the retention, in a measure, of the power of the deltoid. In reality, however, the chances of union were not one in a thousand; and if not union, then necrosis with its consequent shortening; necrosis, too, meaning months or years of inflammation and suppuration, matting the muscles together so that when recovery occurred—almost necessarily by an operation—the usefulness of the limb would be but slight. Resection, on the other hand, offered the complete removal of all injured portions of bone, and with them the most important factors of trouble after such an injury, thus permitting rapid healing, and the smallest possible amount of inflammatory adhesions between muscles, tendons, etc. If the bone had been simply returned, the risk to life would have been greater, owing to the prolonged suppuration incident upon the separation of the necrosed bone and the deep-seated abscesses so common after compound fractures. Against it was the absolute shortening of the arm, with the prospective cessation of growth due to removal of the upper humeral epiphyses.

The actual result, I think, bears me out in the course of treatment pursued; for I hardly think that in seven weeks he would have been in so good a condition, with the wound soundly healed, if I had followed what is often, but falsely, called the "conservative" plan of treatment. I believe that true conservatism indicated exactly what I did. The amount of shortening would not have been much less had the case been left to nature and necrosis. Had this occurred, union of the severed head could not have taken place; and then the same shortening would have obtained, as surely as if the epiphysis had been removed. Army experience has shown that when a portion of the upper end of the humerus is removed for injury, nothing is gained by leaving the uninjured head, since it necroses.

Although not cognizant of this fact of experience at the time of operation, anatomical knowledge, general surgical principles and experience, induced me to arrive at a conclusion by *a priori* reasoning, which I have since found that extended experience had already proved.

I believe, therefore, that, theoretically and from experience, resection ought to be performed for such injuries. It is hardly necessary to say anything about the operation itself, since each case must be a rule for itself, the only point being to remove the bones with as little additional damage to the soft parts as practicable. The wound was dressed antiseptically, and when I transferred the wards to my colleague, Dr. Packard, no suppuration had occurred, and there was not the slightest inflammatory blush about the wound. He did uninterruptedly well, and the wound was soundly healed in less than seven weeks, the greater part at a much earlier date.

Sharply contrasted with this case and its results is that of the patient from whom the next specimen was removed, where the head of the humerus, luxated and partially fractured and protruding through the skin of the axilla, was *reduced* instead of being resected. Here the tension of irritated, lacerated muscles, conjoined with the necessarily imperfect drainage, kept the injured bone bathed in unhealthy pus. This, with the injury, resulted in an osteomyelitis, which necessitated my amputating at the shoulder-joint. I believe, had the head of the bone been removed, a fairly useful limb would have been the result at the end of a few weeks' treatment; while instead, after three months of illness and risk to life, amputation was the best I could do for him.

Compound Luxation (with Fracture) of the Shoulder-Joint.

"———, æt. 30 years, man, three months

ago had his right arm caught by the belting and drawn over a large drum in a position of extreme abduction and probably of extension. The head of the bone was luxated, the greater tuberosity torn off, and the caput humeri thrust through the axillary integuments near the anterior axillary fold. When I first saw him at the Episcopal Hospital, after the accident, he was very pale, with a constant discharge of pus from an opening at the site of the old wound, *i. e.*, near the anterior axillary fold, while the orifice of another deep-seated sinus was seen over the middle of the triceps on the outer side of the arm. A probe introduced into the anterior sinus readily touched the denuded carious head of the humerus. I attempted to exsect the head of the bone, but when prepared to saw it, after its protrusion through the wound, I found such evidences of osteomyelitis as to render amputation at the shoulder-joint necessary. He did well and recovered; but even some months later a sinus existed, doubtless the result of necrosis of some of the fragments of periosteal bone, produced by that irritated structure. As before said, had the head of the injured bone been excised, a useful arm would have probably resulted."

The third and last case is one where a comparatively trivial injury, owing to non-treatment at first, resulted in a condition which demanded resection of the shoulder-joint.

Chronic Arthritis of the Shoulder-Joint: Epiphyseal Abscess of the Humerus.

"Anna M., æt. seventeen years, was admitted to the Female Surgical Ward of the Episcopal Hospital, May 14, 1883. One year ago last May she fell down stairs and struck her shoulder. She was unconscious for a short time, but was soon able to walk home. The arm did not become inflamed, and seemed to the patient well. Nine months after the fall she noticed pain in the shoulder, and an elevated papule formed near the joint, which was opened at the dispensary. This relieved the pain, but left a fistulous tract discharging healthy pus. She attended the dispensary until the 14th of last May, when she was sent into the house, Dr. Seltzer, the Assistant Surgeon on duty, having touched dead bone with the probe. After admission she had pain from time to time, gradually increasing in intensity until shortly before operation. Other free openings for drainage were made by Drs. Simes and Kelley. The probe detected an apparent sequestrum within the humeral head. Diagnosis, epiphyseal abscess.

"The operation showed complete destruction of

the joint, acarious and denuded humeral head, with an abscess about the epiphyseal site containing a sequestrum. The glenoid cavity was denuded of cartilage and roughened. The portions of head and shaft, such as you see, were removed, while all the glenoid cavity was cut away with the gouge-forceps, except where the long head of the biceps was attached. Further details of the operation are unnecessary. The patient was practically well at the end of two weeks. Perfect quietude of the joint at the outset might have averted all subsequent trouble."

What was the condition here after the accident? Probably the bursæ and fibrous tissues surrounding the joint were involved, and the vascular epiphyseal cartilage was congested from the jar and injury of the fall. Congestion of all these parts, instead of being relieved by complete functional rest of the articulation, with the local application of ice, leeches, etc., as appeared indicated, was kept up by the girl following her usual occupation of housework. Although in no sense markedly strumous, yet the tendency was in that direction. As the congestion increased, inflammation and suppuration were set up in the bursæ, the disease spread to the articulation, gelatinous arthritis with epiphyseal abscess supervened, notwithstanding the skillful treatment of my colleagues who, *too late*, had the opportunity of treating the case.

THE TREATMENT OF SOME OF THE EFFECTS OF SEXUAL EXCESSES.

BY JOSEPH L. BAUER, M. D.,
Of Lehighton, Pa.

(Late Lecturer on Genito-Urinary Surgery, St. Louis College of Physicians and Surgeons.)

In studying the works of Acton and Lallemand, one is struck with the singular pictures there painted of the serious results of sexual excesses. We are seized with doubt, and are apt to ascribe them to a highly-gifted imagination. The late Dr. G. W. Beard was also possessed with a similar happy faculty of portraying the same conditions; with the difference that in coining neurasthenia, myelasthenia, and cerebrasthenia, with their numerous attachments, he made some other diseases fit upon the same foot. We had heard a great deal of this book, and determined to study it carefully. A conclusion was reached rapidly, viz., that Americans think, eat, drink, and sleep differently from other nations of the earth, and hence suffer horrible tortures from the several *thenias* above enumerated. A second thought arises, however; we are struck with the fact that

the great majority of conditions therein described are *but the consequences of sexual excesses*, beautified by an elegant nomenclature. In fact, the descriptions have been absorbed *ad libitum* by a quack concern in New York city, with the usual charitable intention of such impostures. We are fully acquainted with the great differences in cases attended by individual surgeons; we acknowledge that sexual excess sometimes produces serious pathological conditions (Erb, Rosenthal), hence we should qualify our doubts somewhat. But when all things are equal, authority, however great, should be cast aside, and stubborn facts alone should rule.

A large number of cases attributable to the effects of excessive venery, have given me an opportunity of testing the value of different methods of treatment, as well as giving me a fair idea of the relative differences between excessive coitus and frequent masturbation. In one of the medical journals of St. Louis of 1882 and 1883, the reader will find an extended delineation of my views. Therein I have endeavored to show that there is an *essential difference in the orgasm, the seminal ejaculation, and in the mental and physical results.*

"When impelled by sexual excitement, the male seeks intercourse with the female, the erectile tissues of the genital organs become turgid with blood (MUCOUS MEMBRANE OF URETHRA ALSO, J. L. B.) (§ 276), and the surface acquires a much increased sensibility: this is especially acute in the glans penis. By the friction of the glans against the rugous walls of the vagina, the *excitement is increased (as it is also in a small vagina and in masturbation, J. L. B.)*, and the impression which is thus produced at last becomes so strong that it calls forth, through the medium of a ganglionic centre, probably situated in the lower portion of the spinal cord, a reflex contraction of the muscular fibres of the vasa deferentia, and of the muscles which surround the vesiculæ seminales and prostate gland. *The high degree of nervous excitement* which the act of coition involves, produces a subsequent depression to a corresponding amount (*ergo, the greater the excitement, as in masturbation, the greater the depression;*) and the too frequent repetition of it is productive of consequences very injurious to the general health. This is still more the case with the solitary indulgence, which (it is feared) is practiced by too many youths; *for this substituting an unnatural degree of one kind of excitement for that which is wanting in another, cannot but be still more trying to the bodily powers.*"*

* W. B. Carpenter, M. D., Principles of Physiology, page 888.

I have also tried to prove that the reasoning faculties may not be impaired, and yet there is a potent change in the volitional qualities of the individual afflicted, which tends to the continuance of a habit formed, over which the will has lost its entire control, notwithstanding a full realization of the consequent pain such sensations may occasion.

"In man, . . . the principal operation of the sexual sensations is in awakening desires and affections, which serve as excitements to the intelligence and as motives to the will; and it is only, under ordinary circumstances, when the two sexes have been thus brought into close relation, that direct reaction of the sexual sensation manifests itself in automatic movements. In cases, however, in which this sensation is excited in *unusual strength*, it may *completely overmaster all motives* to the repression of the propensity, and may even *entirely remove the actions from volitional control.*"* And I have tried to prove, that the volition cannot be aroused by moral suasion only; that the habit cannot be overcome by the barbarous method of infibulation, practiced somewhat by German surgeons; BUT THAT IN BAD CASES THE INDIVIDUAL MUST BE RELIEVED OF HIS FEAR OF WOMAN, AND BE TAUGHT THAT NORMAL COITUS IS HIS ONLY SAFETY.

I do not desire to transcend the intention of this article with a lengthy rationale of the conclusions stated above: future opportunities will permit of a more extended discussion.

Now, what are some of the effects of sexual excesses?

Deep urethral hyperæsthesia, producing irritation of the genital centre of the spinal cord: (1) increasing or decreasing the inhibitory influence which the brain exerts upon the genital function; (2) irritation of prostate gland; (3) congestion of seminal vesicles; (4) spermatorrhœa; (5) stricture of the urethra; (?) (6) nervous disturbances of the intestinal tract, *i. e.*, dyspepsia, flatulence, constipation; (7) palpitation of the heart; (8) impotency (psychical and organic); (9) melancholia, hypochondria, and insanity.

Other disturbances are met with which, however, do not concern us just now. What are we to do when we have to deal with irritation of deep urethra, spermatorrhœa, stricture of urethra (?), and impotency? In fact, cannot all these effects be relieved by medication—local and internal—without resort to fashionable instrumentation?

Is it necessary that we should jam bulbous metallic sounds into every such urethra, and detect a NARROWED CALIBRE and a membranous constriction? In fact, should the urethrotome be considered the special panacea for such discoveries?

In consequence of the continued excitation of the entire genital tract, there is a sequential hyperæmia of the mucous membrane of the urethra as well as a CONTINUED *hyperæsthesia* of the terminal nerves imbedded in the mucous membrane. But, as far as experience, personal as well as otherwise, teaches us, there are but a few isolated cases on record of typical inflammation resulting therefrom. I cannot, therefore, appreciate how it is possible that stricture of the urethra can ensue, unless the laws of pathology are reversed, and we are taught that every congestion long continued must necessarily result in effusion of lymph. I am well aware that the constant exercise of a reflex act may influence muscle, as well as alter the function of nerves, but I have not learned in how much such continued reflexes influence elastic tissue, upon which urethral calibre depends, unless altered by the products of inflammation, *'unless it be the circular muscles of the urethra.* The discharge which accompanies some of these effects can surely not be attributed to an inflammatory condition, since the mucous membrane contains numerous glands, which supply a lubricating fluid, or modify the semen. It is self-evident that overaction of the entire nerve-supply of the genital tract produces also over-action of many of the secretory functions.

Clinical experience has demonstrated that the *consequences of sexual excess are to be found almost in toto in the nervous system, and that few or no ORGANIC CHANGES take place.* It might be asked, if this be so, why is it that—given urethral hyperæsthesia from these stated causes—we use gradually increasing sizes of sounds, and accomplish much with them? I might also ask at this juncture, *why does this hyperæsthesia exist along the entire urethra, and is intensified in the deeper portions?* Physiology teaches us that the intensity of the orgasm is experienced in the prostatico-membranous portion of the urethra, where the nerve-supply seems to be more closely approximated, greater, and connected with ganglionic bunches. The corollary would be correct, therefore, that at this point we should expect to find the greatest effects. And it is to this point that Profs. Otis and Gross, the late Prof. Brown, and Dr. Mastin, of Mobile, seem to direct their surgical engines. But Prof. Gross, in a late work on Diseases of the Male Genital Organs, lays enthusiastic stress upon the

* Wm. B. Carpenter, M. D., Principles of Human Physiology (Smith), page 684, § 356.

miraculous work that the urethrotome has done in these cases.

Now, let us examine the *modus operandi* of Prof. Gross. A patient presents himself to the doctor suffering from the effects of masturbation. The penile organ is small and flabby; the meatus puffy, congested, and the lips agglutinating. A bulbous metallic sound of small calibre is introduced, demonstrating considerable hyperæsthesia of the urethral tract, and *some difficulty of moving onward*. Upon its withdrawal an *impediment is felt in the membranous portion*, but a little exertion allows the instrument to glide over it. When withdrawn the distal end of the bulb is crowned with a gleetty secretion. The circumference of the penis is then taken, the ought-to-be calibre decided; urethra-metre introduced; and at points of resistance, whether in the anterior, middle, or deep portions it is cut to the proper calibre. A steel sound is introduced frequently, and the patient returns home a happy man.

Before proceeding to criticise this method of treatment, it were well to consider a few anatomical points.

a. The urethra is a membranous tube, with diameters varying in different portions.

b. Elongation of the canal is fostered by the existence of longitudinal muscular fibres, chiefly in the deep urethra.

c. A change of urethral diameter is governed by elastic tissue and circular muscular fibres.

It seems to me, therefore, that an excessive irritation of peripheral nerves would exert itself upon the *muscular structure, depending upon such irritation for their physiological action*. If such be possible, can not we assume, that the *opposition to distension in the application of the urethra-metre is due to spasm of these circular and longitudinal muscles*? And is this not the case, where spasmodic stricture is produced by the use of sounds, and other causes of peripheral irritation? I am well aware that this does not coincide with the dictum of Prof. Otis and his disciples, who hold that the cause of spasmodic coarctation must be sought in the organic narrowing of urethral calibre. But it is a clinical fact, that these very coarctations, which are so effectually removed by urethrotomy, can be, and are, removed by the careful and progressive use of sounds, and the anti-spasmodic influence of the constant electrical current. And I believe also, that the sounds have the same effect upon a nerve that nerve-stretching has upon sciatica and locomotor ataxia. Indeed, I had the opportunity of examining a patient who had been suffering from the effects of masturbation, and who had been cut

by one of our reputed eastern urethrotomists, in which no relief whatever ensued, but the ailment subsequently subsided by a purely sedative treatment.

(To be Continued.)

THE HEALTH OF WOMAN AS COMPARED TO THAT OF MAN, ESPECIALLY IN RELATION TO MARRIAGE.

BY GEORGE HAMILTON, M. D.,
Of Philadelphia.

This subject has for some time past received a good deal of attention, and, during the few past years, it has been made to assume increased importance, not only in medical lectures and writings, but also in the transactions of associations established for the advancement of hygiene. As a rule it will be found that the status of woman in regard to health is represented to be much lower than that of man. In this point of view it is not surprising that, from the time she has arrived at marriageable age, attention is chiefly given to this period of her life, and expressions of regret are often heard that so many are ill-prepared for the duties and exigencies of married life. But while this unfavorable view is in many cases justified, is it not far more frequently entertained than a due consideration of the facts pertaining to this subject will warrant? Is there anything, at the moment of birth, or for years after, indicative of a more feeble constitution, or greater proclivity to disease, in the female than in the male, so that doubts might arise as to her capacity to occupy the future position assigned her by nature? On the contrary, statistics show that more male than female children are still-born, and also that more males from birth to the fifth year perish than females, chiefly owing to their greater disposition to disease of the brain. As the female approaches womanhood, and for some years after, especially if she marry very young, the chances for health and longevity are to some degree diminished. Taking the entire period of child-bearing, statistics are not in accord as to the comparative mortality; but beyond that period the chances, for health and length of days, turn strongly in favor of the woman. But this prolonged existence may readily be explained in the fact that not very many women are addicted to the use or abuse of intoxicating liquors—an abuse of a character, as all statistics prove, to cause in men an enormous amount of physical and mental disease. To agencies of another kind are often attributed the unfitness of very many females for the duties and trials of wedded existence. Lec-

turers and writers upon this subject have, as it were by common accord, placed in this class many of the daughters of wealth and fashion. In this class, as in every other, may be found those who, by inheritance or otherwise, possess feeble constitutions, and who in matrimony may not only incur risk of further injury to health, but whose offspring may have constitutions similar to those of the mothers. Another class, having good health and constitution, may, through a constant, protracted course of fashionable dissipation, destroy or greatly impair both, and may thus, so far as matrimony is concerned, be placed in the category alluded to. The number in both classes is, the writer has reason to believe, comparatively small; so small, indeed, as not to justify a general charge against this condition of society, as an appeal to facts may prove.

Let us, for instance, stroll, at certain hours of the day, through that portion of the city which, par excellence, may be regarded as one of the most fashionable and wealthy, having as its centre Rittenhouse Square, and what will at once gratify and attract our attention so much as the numerous groups of children in and about the square, of every age, from the infant of a few months or a year, up to children of perhaps eight or ten years? Infants, too young to walk, are being trundled about in all directions, their plump forms, rosy complexions, bright eyes, and cheerful looks, giving visible evidence of their excellent health. Others of suitable age are, by direction of intelligent parents, instructed to avoid the coach, and thus bring the muscles of the limbs into action, and thereby increase the appetite and power of digestion, so as to improve the strength and tone of the whole system. When old enough, the children (girls as well as boys) are provided with a variety of implements used in various amusing and healthful games, or with one or other of the many machines now in vogue for rapid and pleasant locomotion. But again, the residences of these children are nearly always large, admitting perfect ventilation, and provided with conveniences that conduce, in no small degree, to the comfort and well-being of the occupants. Another point, greatly advantageous to daughters, from childhood to womanhood, is that, as a rule, the parents are educated and refined, and are therefore the better able to discover and carry into effect all that pertains to the physical, intellectual, and moral welfare of their children, especially as regards the daughters.

Thus far, it may be said, very good; but, arrived at womanhood, then comes the trial, by en-

tering upon a round of fashionable dissipation that too often attends the social status in view, especially when no incumbent occupation or duties interpose an obstacle. But there is another side to this picture, in the fact that only a part of the time is thus employed, and a very large number of these devotees of fashion spend much of their time in riding in the open air, or, like the ladies of England, in promenading—the best of all exercises. Again, as soon as the season arrives for leaving the city, a very large majority close their houses, repair to their summer homes, or to the almost innumerable places of resort by the seaside, or to situations (in rural sections) noted for their salubrity. Here their enjoyments are in a great measure of an active kind, and are thus productive of increased health and strength.

That there are other, and quite opposite, conditions of society, in which the females are incomparably less healthy than those in question, is beyond doubt—and have far less qualification for matrimony, or longevity.

But what are the actual qualifications of man for matrimony, as compared with woman? If the statistics of some writers be correct—that the mortality of woman, during the whole period of child-bearing, is about the same as that of man for the same period—then the conclusion is inevitable that some deleterious agents are in operation upon man; for women must surely encounter certain risks peculiar to pregnancy and accouchement.

As intimated above, the use, or rather abuse, of intoxicating liquors, is so common with men that probably ten of them suffer mentally and physically from this cause for one woman. But this is not all; for, as is well known, the stimulus of alcohol, in any form, is too often the stimulus of every evil passion; and as men generally defer marriage to a later period than women, so are they more apt to become the victims of dissipation of every kind, and consequent disease or debilitation. This condition exists in every class of society; and where the pecuniary condition is abundant, the temptation and inducement are thereby increased.

From this statement, may it not very often happen that favorable qualifications for matrimony are deficient on the side of the man rather than of the woman?

The writer is aware that this view may not accord with that of the gynecologist or the special accoucheur; but would not the large amount of this special practice induce those engaged in it to imagine that such cases are far more numerous than the general practitioner could admit?

In the "Report of the Medical Association of

Missouri for 1883," may be found a well-written and elaborate paper upon this subject. After making due allowance for such cases in men—accidents, dissipation, or other agencies—and allowing in like manner for such influences as may at certain periods affect females unfavorably, Prof. Schenck, the author of the paper, seems inclined to the opinion that woman has the greater vitality, and that under equal conditions she has a better prospect of length of days. This opinion, granting that equal conditions were possible, is well-founded; but while man, in general, has greater muscular power, that is no evidence of greater or even equal vitality; for it not unfrequently happens that neither the man nor the woman of large bone and muscle has the hardihood and endurance of persons of moderate conformation. But was it not absolutely necessary, in view of the destined life of the woman, that an all-wise Providence should endow her with an amount of vital endurance commensurate with the tax upon her constitution that pregnancy, child-birth, lactation, and the care of her offspring, would impose? In regard to ability to support attacks of fever or other acute disease, the writer has generally found the advantage to be on the side of the woman; and the accoucheur and the gynecologist, in particular, could not fail to have observed the frequent recuperation of females after extensive surgical operations, and immense losses of blood occasioned thereby, or as occur in cases of abortion and accouchement.

HOSPITAL REPORTS.

TREATMENT OF EPITHELIOMA OF THE UTERUS.

CLINICAL LECTURE DELIVERED AT THE LONG ISLAND COLLEGE HOSPITAL,

BY DR. A. G. C. SKEFE,

Professor of Gynecology and Visiting Surgeon to the Hospital.

Reported by EDWARD DEVELIN, M. D.

GENTLEMEN: The patient whom I here present to you is a married woman, thirty-five years of age. She was married at the age of fifteen, and has since borne eight children, the last child being now eighteen months of age. Six months ago she was compelled to wean the child, owing to exhaustion on her part from a hemorrhage from the uterus. She states that she underwent an operation for this difficulty, but that it afforded her no relief; that the hemorrhage still continued from time to time. She also informs me that with none of her other children did her menstrual flow commence until she had weaned them; but with the last child, after nursing for some months, she had, on two occasions, a flow which probably was menstrual; but following these, she had repeated

attacks of metrorrhagia, and it was for this latter that she was operated upon. As I before stated, this treatment was useless; and at the present time there is more or less hemorrhage occurring about every third or fourth day. She is also suffering intense pain, and during these periods becomes greatly prostrated.

On looking at this woman, we see a person who is not at all emaciated, but, on the contrary, one who has rather an abundance of adipose tissue. She is extremely anæmic; her pulse is now about one hundred and twenty, more like the pulse of a little child, weak and feeble, owing to these continued hemorrhages. The complexion has a peculiar cachectic appearance, accompanied with a slight flushing of the cheeks; the skin is dry, harsh, and ill-conditioned. She is suffering from general derangement of nutrition. As the woman now rises to leave the room, she at once places her left hand over the region of the ovaries, the pain in the pelvic organs being so intense; you also notice that her gait is feeble and unsteady.

An examination has previously been made as to her condition before entering the lecture-room, and I will now demonstrate upon the blackboard the appearance of the uterus. When we secure such a history as we have just now received, we can almost diagnosticate our case at once without further examination. It is certainly out of the ordinary line of health for a patient to have recurrence of the menstrual periods, if such they were, so soon after the birth of her child, which, in turn, were followed by this metrorrhagia, which from the exhaustion ensuing, necessitated the weaning of the child.

When we take all these points into consideration, together with the severe pelvic pains, we are convinced that there is some serious difficulty, and that an investigation is needed.

Now, we find here that the uterus is much enlarged in both body and cervix; the cervix, however, is more in proportion than the body. The os externum is widely opened, and the outer portion of the cervix is rough and ragged. If you can imagine the cervix looking very red and angry, bleeding under the slightest touch, you have a fair idea of the condition I desire to impress upon you that the cervix presents. In addition to this, you must remember that it is greatly increased in size. We have then not only all the evidences of sub-involution, but more than that: we have here a new growth involving the entire canal of the cervix; and by this time perhaps nearly every one of you is ready to state that we have here a case of malignant disease. She is but thirty-five years of age, and has not yet entered the descending plane of life, which is, as we know, rather early for malignant disease to appear. I have no doubt, however, that such is the case, and that it is with malignant disease that we here have to deal.

The question is as to the form of malignant disease. This new growth, of irregular, cauliflower formation, indicates epithelioma; and the intense density of the other portion of the cervix suggests that it may be a development of epithelioma upon a scirrhus base; the epithelioma choosing the mucous membrane, and the scirrhus choosing the deeper tissues; this may sometimes occur. This at least is my diagnosis in relation

to the pathology of this growth of new tissue here developed.

The patient, although very fleshy, is extremely weak; and she is beginning to show that condition of nutrition of the skin which gives us this cachectic appearance. It is a strange fact that this kind of an organization, those having a superabundance of fat, are more likely to develop malignant disease than those of spare, lean habits. It is this kind of organization which is predisposed to malignant disease. It is a rare occurrence for a thin, wiry individual to develop malignant disease in the earlier years of life.

Another point worthy of notice is the pain which the patient suffers; for you remember that when the intra-vaginal portion of the cervix is involved in malignant disease, pain is the exception to the general rule. So that when we read of the diagnostic pain of cancer, we know that the statement is misleading in relation to cancer of the cervix alone, for unless the upper structure of the uterus be involved in this malignant disease, pain is very rarely or never felt. This then, placed in relation to the case now before us, would lead us to accept the fact that the upper structures of the uterus are also involved; and our previous examination has proved that it is so, and therefore no exception to the rule.

Having now obtained all the facts in relation to the case, the question arises, What can we do for her? You will first naturally ask, What was the previous operation? In all probability, it was no operation at all. I have two very good reasons for making this statement: the first is, that no evidences of any operation ever having been performed can be discerned; the second is, that the man who performed this so-called operation, I have learned, has since been arrested for practicing without a diploma. This is a painful thing to report, when the life perhaps of a fellow creature has been involved by such criminality. But it is far from unfrequent that we find such charlatans choose the uterus as their field of operations, as their maltreatment is not likely to be exposed. They can damage this organ without much danger of their trickery being discovered, and it is in the field of gynecology that these charlatans work such ruin and mischief. The man in this case, before us was not detected in his humbuggery, for such I am sure that it was; although we have here but too evidently, in the suffering of this poor woman, a blight and disgrace to our profession and government, that such men, at the present enlightened day, are allowed, even for a short time though it may be, to abuse the noblest calling that we have the honor to represent.

I am reminded of this very forcibly by the facts relating to a lady who came to my office recently with a friend, stating that she believed she had some uterine trouble, and wished for an examination. I asked her who was her attending physician, and, had she given me the name of some reliable man, I should have given due weight to his diagnosis; but she stated that I did not know him, and declined to mention his name until I had made my examination and given my diagnosis. I had therefore nothing to do but make my examination, which I carefully did. I then found a small cyst protruding from the cervix, a mere trifle, which was only peculiar because it was pro-

truding and not imbedded in the walls of the cervix. It was simply superficial, and much more easily removed than a wart upon the hand, and with as little danger. She was remarkably healthy in every respect; her sexual organs were perfectly developed, and free from disease. This little cyst being near the canal of the cervix, had given rise to a hyperæmic condition and slight leucorrhœa. I assured her this was of but little consequence, and could easily be removed; and had she not held me to certain restrictions, I should have removed it at that time. She then informed me that her physician had told her that it would be necessary to perform an operation, involving the amputation of the cervix, and that his fee for this operation would be three hundred dollars. Her friends, however, advised her before consenting to this operation to consult me. I removed this small cyst shortly after, and a few days following she presented herself at my office perfectly well. Had she been guided by this other man, she would probably have lost the neck of the uterus, and paid a large fee for the mutilation.

I am disposed to be charitable to the profession in general, as they have been charitable towards me; and when we make an error in judgment after we have sought knowledge in every channel, we are not held accountable. But when a man intentionally and wilfully submits patients to humbuggery, as I believe was the intention in this case, I can find no language strong enough to be used against him.

The question in the case now before us is, can we operate? I frankly tell you no; for this reason: If we can get above the diseased tissues we can operate, and I think in many cases prolong life. But when we have the disease extending above the cervix, or involving the tissues around the uterus, operations in my opinion are generally useless, or at most palliative. It is stated by some that we may do much by removing as large a quantity as we possibly can of the abnormal tissue, by means of the thermo or galvano cautery, as by this means the hemorrhage is checked for a time. Beyond this, however, I think no good results are secured in these cases. I have seen but very few cases where there has been any reason to believe that any success ultimately attended the operation.

The operation of entirely removing the uterus is now becoming fashionable among surgeons, and you may perhaps ask, why not do so in the present case? I can only say, that to perform this with any advantage you would have to operate very early in the disease, before any of the tissues surrounding the uterus were involved, and before the patient's health became markedly deranged; and I must say that I have never had the courage to operate, so that I may be somewhat behind the age in this department of gynecology. When the disease does become established, removal of the entire uterus may fail to relieve the patient; and even should it prove successful, so far as the patient surviving the operation is concerned, will you give her a longer lease of life! The operation is so formidable a one that I have never performed it in these cases of malignant disease, and I do not know that I ever shall.

I believe that when we have statistics of some

hundreds of these cases of the removal of the uterus for malignant disease, and compare them with an equal number of cases of malignant disease of the uterus which have not been operated upon, that the ones not operated upon will give us the best results. Removal of the uterus in malignant disease is only a slight possibility of cure, and I have not taken kindly to the operation. It may be timidity on my part, if such you choose to term it; but I would rather be among the timid than among the daring, and I am willing to wait until we have more positive knowledge regarding this heroic treatment of cancer of the uterus. Palliative treatment only is then left for us in these cases, in my opinion.

I was very much pleased to notice a recent article by Dr. Reeves Jackson, of Chicago, in which he takes precisely the same ground as I do in relation to these cases, stating his views in a most concise and clear manner.

You must not, however, abandon your cases when the disease has advanced beyond the reach of operative surgery; you can do much toward relieving the sufferings of the patient, and to a very limited extent prolong their days.

In the first place, the intense pain is to be relieved by the administration of opium in quantities, no matter how large they may be, sufficient to relieve the suffering; administering the opium regularly. You have doubtless all heard me declaim earnestly against the use of opium in the management of benign diseases of the uterus and ovaries, because of the danger of establishing the opium habit. But in the malignant disease of these organs, I pursue exactly the opposite course, and establish the opium habit as soon as possible, believing it to be the only way to secure comfort and relief from pain in this most distressing affliction. I have also found that by the use of a tampon of marine lint, the patient could be guarded from these dangerous attacks of hemorrhage; and more than that, the peculiar discharge characteristic of this disease is taken up and disinfected by the tampon—so that the patient is relieved from the irritation which usually follows about the introitus vulvæ, and also from the continuous offensive flow. The tampon should be changed every day, or every night and morning; a skillful nurse can be taught to employ it most effectually. I have found this treatment to afford the patient great comfort. I have also found in quite a number of cases—I think seven in all—of epithelioma which commenced in the cavity of the body of the uterus, that the hemorrhage could be checked for a time by simply removing the cauliflower growth with the curette, and subsequently injecting the uterus with a saturated solution of the chloride of zinc.

As regards the constitutional treatment of epithelioma of the uterus, I have but little faith in any remedies in the advanced stage of the disease. If we could detect the tendency to malignant disease, we might do much towards preventing its development by good hygienic and tonic treatment, especially by the use of iodine and arsenic; and we may even gain something by such treatment in the incipient stages of the disease; but in these cases as we usually find them it avails but little, in my opinion.

In comparison with the case we have just seen,

in which the whole uterine and probably surrounding tissues are involved, I will mention that of a case now in the hospital, in which the disease involves the neck of the uterus alone. In this case amputation of the diseased portion is perfectly practicable and always justifiable. I shall therefore in a few days amputate the neck of the uterus in that case, removing all of the diseased tissues, with the result, I have no doubt, of tending to prolong the life of the patient.

MEDICAL SOCIETIES.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

(Concluded from page 559.)

Dr. Van Harlingen said that with regard to the general treatment of syphilis, the ground had been so well covered by Drs. Ashhurst and White that little or nothing remained to say. There are certain problems, however, that present themselves in connection with the management of late syphilis, which had not been touched upon, and which are yet of great practical importance. One of these relates to the period during which treatment should be continued in cases seen for the first time in the later stages of the disease. For instance, a patient presents himself with a single late lesion or group of lesions, of the skin, or an ulcerated pharynx, a muscular involvement, or a nerve or cerebral lesion. A few weeks or longer may suffice to remove the outward evidence of syphilis; but how long should treatment be continued, not merely to prevent relapse in the original spot, but to prevent possible subsequent manifestation of the disease in some more important spot? The speaker said that his custom in such cases is to touch the lesion with iodide of potassium, beginning with five-grain doses, rapidly increased until the lesion yields or until the limit of tolerance is reached. When the lesion yields, then mercury is to be added to the potash salt, and after a little time the latter is gradually withdrawn and mercury alone is administered for the space of at least six months after the disappearance of all signs of disease. This the speaker considered the safest method of treatment in late syphilis, and in practice he had usually found that it gives the patient permanent relief. Further observation, however, is required on this point; for if syphilis can be taken in hand at any stage and treated with the same probability of entire subsequent immunity as when treated from the beginning, the method and duration of such treatment should be settled. At present, further exact investigations on this point are demanded.

Another important point is the realization of the fact that there comes a time in the history of late syphilitic lesions when specific treatment is of no avail. Specifics will remove the new-cell infiltration which constitutes the lesion, but a cicatrix may be left behind, as in stricture of the œsophagus or rectum, or as a sequela of a gumma of the brain, which is as much a morbid product as the original syphilitic lesion, but is entirely unchanged by the administration of iodide of potassium or other specifics, no matter in how large doses these may be given. In such cases huge doses of rem-

edies are vain. The dose should be rapidly increased, held for a short time, then diminished if found of no avail, or changed for some other form of treatment. Sometimes a simple tonic, as the tincture of iron, will cure when specifics have failed.

Dr. W. R. D. Blackwood remarked that he first saw syphilis and chancreoid on a large scale whilst stationed at Lexington, Ky., in 1863. His division was so affected by venereal diseases as to compel military supervision of houses of prostitution, and he made a personal examination of a large number of women twice weekly for over two months, all diseased females being removed for treatment to a special hospital. He was thus enabled to connect cases in the troops with the source of infection, and to test with certainty the effect of treatment of syphilis prior to the advent of a chancre in men reporting a suspicious intercourse. In no instance did such treatment avert constitutional results. As three regiments of his division were recruited from this city and Schnylkill county, he had additionally, in many instances, an opportunity of following up the after-history of men treated for chancre and chancreoid. He invariably, during the nine years of his army experience, thoroughly cauterized all venereal ulcers of the genitals with fuming nitric acid; and with the exception of a year, during which he followed the prevailing plan of letting chancreoids alone, he always does so, now being satisfied that the sore is not only thus more quickly treated, but that its tendency to auto-inoculate is controlled. Subsequent to cauterization, he used bismuth or similar mild dry powders. He frequently employed common *brown* sugar, which acted nicely. He had tried as an experiment molasses and glucose; and also black and yellow washes, aromatic wine, and the usual routine dressings, but without good effect. Dr. Blackwood, after thorough trial, was satisfied that iodoform was of no value whatever, either externally or internally, in syphilis, chancreoid, or any other disorder. It was offensive to both patients and associates, and was used blindly by surgeons and physicians as a prevailing fashionable remedy. He let buboes alone unless they threatened suppuration, when he poulticed and incised freely. Potassio-tartrate of iron he valued highly, and the reason it failed with most surgeons was because they gave it in small doses—two to five grains. He never gave less than thirty grains—usually a drachm, four times daily. It is the most rapid blood-making ferruginous salt we have; does not constipate, and it certainly excels any other drug in controlling destructive ulceration. He added alum to it if diarrhoeal action set in.

Dr. Blackwood objected to mercurial inunction in syphilis, as dirty, inconvenient, and causative of eczematous disorders. He did not use iodine or its compounds in secondary manifestations, but preferred bichloride of mercury throughout, even in tertiary. In the latter stage he used potassic iodide sometimes, especially in syphilis of the nervous system. He valued stillingia very much, but it must be a good preparation. He saw excellent results from it while stationed in northern Alabama and other southern states for five years after the war. The doctors outside the large cities there were as ignorant as the people generally, but the negroes and old women knew the value of

stillingia, which is the basis of the "Cherokee cure." He always gives the compound fluid extract in full doses, with the mercurial or iodide. Treatment was maintained for three years. He avoided salivation, and believed in the tonic effect of mercury according to Keyes.

Dr. Blackwood liked the hypodermic injection of bichloride, adding to it the chloride of ammonium if the patient did not strenuously object, although the operation is painful. He never had abscesses as a result, and if the needle is deeply buried this accident will not occur. He has seen many of his army patients since the war who are in perfect health, and who have now families free from constitutional taint. As the professional attendant of several houses of prostitution in this city for twelve years past, and from twenty-two years' observation, in which time he had treated a very large number of both sexes of whites, negroes, and Indians, in military and civil life, he was satisfied with his method of treatment as the simplest, the quickest, and the best to insure a permanent cure in any case.

Dr. De Forest Willard said that the treatment of chancreoids beneath the prepuce required extreme care. He had himself tried the plans of cleanliness, and syringing, and packing, and had carefully watched this form of treatment in the hands of others. "Buttonholing" and extensive sloughing had frequently followed, even in hospital practice, where strict surveillance was possible; in private practice, even when the individual realized the importance of strict compliance with directions, the environments were often unfavorable to frequent retracy. He decidedly preferred to have a sore, concerning whose size and tendencies he had seen many errors in diagnosis, open and visible. The removal of a portion of the prepuce, and, as quite frequently possible, the cutting away with it of the sore itself, was a no worse operation at this time than at any other, as the cauterization of the raw edges, during anaesthesia, was painless, and much time was in the end saved.

An apparently contracted prepuce was, as the speaker had shown in a previous paper, an easily remediable condition in young children; but as he had then said, that whenever any symptoms arose referable to this stenosis, "a prepuce freely movable over a normal glans should be secured," so now when the youth has arrived at sufficient years of indiscretion to voluntarily contract a venereal sore, and had never been able to accomplish retraction, it was sufficient evidence that actual narrowing existed, and the sooner that a healthful standard was reached, the better would be the result. He certainly would not dare to retract the prepuce forcibly and cauterize, as Dr. A. had suggested. It is claimed that chancreoids are not specific sores; yet all who speak from large experience in dealing with them will acknowledge that they are vicious, destructive in their tendencies; that they are not self-limiting, but that they are checked only by the resistant power of the individual, either aided or unaided by remedial measures. Let the patient be non-resistant from any cause, and just in proportion to his disability will be the destruction. This is not the course of simple inflammation, hence it should be met actively and vigorously.

Each one has his favorite caustic; he preferred the acid nitrate of mercury, but would state that the worst case of salivation which he had ever produced, was caused by applying it to a chancre upon the os uteri, the liquid being permitted carelessly to trickle down the posterior vaginal wall.

In regard to tertiary syphilis, it had always been his practice to substitute a tonic course of treatment for the specific remedies, during one or two weeks of each month.

Dr. Packard thought that the term "specific" might justly be applied to the chancre or soft sore, by reason of the peculiarities in its character and course, distinguishing it from the initial lesion of syphilis, as well as from other sores. He thought the excision of such soft sores unphilosophical and injurious, as simply enlarging the extent of diseased surface; moreover, as the action was local only, and never productive of constitutional symptoms (of syphilis), there was no adequate object to be gained by such a course. He preferred the milder caustics, and had used with advantage the stick of nitrate of silver, dipped in fuming nitric acid; this seemed to him more efficient than the nitrate alone, and perhaps less severe than the acid alone. He believed chromic acid, and the chloride of zinc, either in saturated watery solution or in paste, answered very well.

He advocated slitting up the prepuce to expose chancroids; believing that it is better to know just what we have to deal with, and to obtain ready access to the whole of the affected part. The preputial sore thus formed is under control from the outset, and need not give any anxiety.

As to sloughing sores, and their treatment by means of powdered white sugar, Dr. Packard stated that he believed he had been the first to use this article as a dressing in cases of hospital gangrene, at the suggestion of the late Dr. Le Conte, in 1864. The results obtained had been published in the *American Jour. of Med. Sciences*, for January, 1865. Dr. Packard was then acting as consulting surgeon to the U. S. A. Hospitals at Haddington and at Beverly, N. J., and a very large number of bad cases of this kind were under care at both places.

He thought the corrosive sublimate dressing recently proposed, might be of use in sloughing chancroids, and had had such favorable experience with eucalyptol in cases of gangrenous stumps and other wounds, that it seemed to him worthy of trial here also.

There were many other points of great interest in the subject under discussion, but he had nothing to add to what had already been said by other speakers.

Dr. Ashhurst closed the discussion.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, March 6, 1884, the President, R. A. Cleemann, M. D., in the chair.

Dr. Wm. Goodell made the following

Correction of a Misstatement:

"At the last meeting of this society I made a misstatement with regard to that distinguished ovariologist, Mr. Tait, which I greatly regret, and

which I wish here to correct. I was misled by some remarks made by Dr. Sutton at the last meeting of the American Gynecological Society. These were so reported as to convey to my mind the impression that Billroth was the only European operator who did not refuse any case of ovarian tumor, however unpromising it was, and that Mr. Tait—to borrow Dr. Sutton's language—"does not remove many large tumors, those which weigh from sixty to sixty-five pounds, with extensive adhesions," etc. In quoting this, by a careless slip of the pen, I changed the word 'many' into 'very,' and in addition, I wholly misapprehended the purport of the above sentence. Dr. Sutton has since, in the *Medical News* of February 23d, explained that he did not mean that Mr. Tait selects his cases, for he is 'not aware that this British ovariologist refuses to remove a tumor because it is large;' but that 'Mr. Tait has the largest line of ovary and tube cases and the shortest line of big ovarian cysts, of any man I (Dr. Sutton) visited in Europe.' In making this correction here, I wish to repair the injustice which I unwittingly did Mr. Tait before this society.

Dr. Goodell then exhibited an

Extra-ovarian Cyst,

with the following history: The lady, aged 28, and the mother of four children, had a miscarriage early in last October. At that time her family physician discovered the tumor. It slowly grew, but gave the lady so much inconvenience from pain and pressure that she was brought to his office late in the following December. It was not large, but was very sensitive, and was diagnosed to be an ovarian tumor. Both ovaries were removed early last February, and the lady recovered promptly. The peculiarities of the cyst were to him unique. The ovary lay to one side of a thick-walled cyst, and at such a distance from it that the cyst could have been removed without injury to the ovary. The latter was, however, extirpated along with the cyst, because it was diseased. Hitherto all par-ovarian cysts which he had encountered were thin-walled, and contained a clear fluid. But this one had thick walls, and contained a turbid brown fluid. It started from the left broad ligament, and was adherent to the bladder, omentum, and abdominal wall. Another point of interest was the fact that the right ovary had doubled its size from follicular degeneration, and yet pregnancy had taken place.

Dr. Robt. P. Harris suggested the possible existence of a third ovary, as the starting point of the tumor. He also thought that the presence of a third ovary might explain the persistence of the menstrual flow in some cases, after the operation of double ovariectomy.

Dr. Goodell also exhibited a

Coccyx Removed for Coccygodynia.

The patient had met with a fall down stairs some years previously, and the injury was followed by a vaginal abscess of some kind. She had all the classical symptoms of a very bad coccygodynia, and had fallen into a nervous condition which bordered on insanity. Dr. G. had intended merely to sever the nervous attachments of the coccyx by the sweep of a tenotomy knife; but after the patient had been put under ether, the

tip of the bone was found unnaturally movable, and giving distinct crepitation. The loose bone was, therefore, removed, and as the articulating surfaces were found rough and denuded, the whole coccyx was removed by bone forceps. Great relief followed this operation.

Although he had seen very many cases of coccygodynia, this was the first case on which he had operated. In a very few traumatic cases, he had wished to operate, but was not permitted to do so. The vast majority of these cases are, in his experience, those of nervous or neuralgic coccyx, and they get well in his hands under rest, massage, electricity, and appropriate constitutional treatment. The great difficulty, in cases of severity, is to decide between the nervous mimicry of the disease and pure traumatic coccygodynia, in which positive lesions have been sustained and their effects have not yet passed away—as for instance in a sprained or a fractured coccyx, or in a rheumatic, a gouty, or an inflamed coccyx. There is yet another difficulty in the way of diagnosis, for sometimes an injury received in an hysterical woman is followed by local nervous phenomena, which will last long after the original lesion has been cured. For instance, on one occasion, he had been so greatly deceived in the diagnosis between traumatic and nervous coccygodynia, as to make him very cautious in resorting to the use of the knife. A highly intellectual lady, who spent her leisure in reading metaphysical works, received an injury to her coccyx by the sudden "bucking" of the horse on which she was mounted. She was, at that time, suffering from nervous prostration, and the blow started up very exacting coccygeal symptoms. Dr. Goodell found retroversion and a prolapse of both ovaries. These dislocations were remedied, and the patient put on a vigorous constitutional treatment; but she grew no better, and an operation was proposed and agreed to. As soon as the day and the hour were decided upon, she lost all pain in her coccyx, and has not since had a return of it. This happened about six years ago. On another occasion, he saw a very obstinate and severe case of coccygodynia, which he had been treating unsuccessfully for a long time, and which had a traumatic history, quickly disappear under an exciting family jar. In view of this experience, he believed it always safer at first to consider coccygodynia as a local expression of a general neurosis, and to treat it accordingly.

Dr. J. H. Packard asked why Dr. Goodell had preferred the bone nippers to disarticulation in the first case.

Dr. A. H. Smith asked if Dr. Goodell had removed the entire coccyx. (Dr. Goodell was not sure, but thought so. There had been an abscess in connection with the injury, and the bone was dead and somewhat necrosed; he had cut off one piece with the nippers and then disarticulated the remainder.) Dr. Smith continuing, said there had been suppurative action probably following ankylosis. Such a condition might result from injuries received in labor, or from falling astride a chair-back or a rail. Most cases were reflex hysterical or uterine pains, as will be proved by the freedom from tenderness when the finger is pressed on the coccyx when making a vaginal examination. He has never removed one, because

he has seen such poor relief from the operation in any cases that have come under his observation. Why should relief come unless all the nerves and other painful tissues be also removed? He will be glad to hear the result of the operation in the case reported by Dr. Goodell this evening.

Dr. Packard demonstrated to the Society a new method of applying *Axial Traction* to any ordinary obstetric forceps. The device consisted of two steel hooks arranged to catch in the fenestra of the blades of the forceps, and terminating in rings through which a wooden handle is to be passed. The handles of the forceps are to be lashed together.

Dr. Smith remarked that Dr. Tarnier's first suggestion was to pass a cord through holes drilled through a widened portion of the blades at the point at which handles are now attached. The hooks exhibited by Dr. Packard did not draw from the right point, and he thought there would be difficulty in adapting them when the head was high up.

Dr. Goodell thinks that Tarnier was anticipated in the cord attachment by another French physician.

Dr. B. F. Baer read a paper on

The Significance of Metrorrhagia About and After the Menopause.

Metrorrhagia recurring about the menopause is as likely to be the result of disease of the uterus or its appendages as it is at any period previous to that time. The popular belief that floodings at the change of life are physiological often results in harm. That the blood-loss is depuratory or critical, and that it protects the vital organs from injurious congestion, is erroneous. Where health exists, the cessation of menstruation will be attended by no more aberrations of function than are seen in its establishment. An analysis of twenty-two hundred cases treated in hospital and private practice shows that nearly the same number of women sought service during the establishment and the decline of menstruation, and it further shows that the numbers rapidly increase as the period of greatest fecundity is reached, and decline after it is past.

Epithelioma of the cervix may result from injury of that organ, but also requires some peculiarity in the structure of the tissues which renders them susceptible to an induced dyscrasia. When a woman, in the midst of the fertile period, suddenly ceases to bear children, there is often some local cause for it. There is some causative relation between acquired sterility and cancer. It is safer to believe the disease of local origin, for we will then endeavor to discover and remove all sources of irritation, and possibly prevent its development. Detailed histories of a number of cases are given to illustrate the truth of the positions assumed. Where the menopause is retarded beyond the usual period, the cause can often be found in some diseased condition connected with the sexual system, and, as a rule, it is an old-standing trouble. When metrorrhagia recurs after the menopause has been fully established, it is almost invariably the result of a pathological change in the tissues of the uterus.

Dr. Goodell agrees almost wholly with what Dr. Baer has said; he thinks the dangers of the men-

opause much overrated. Cancer and fibroids of the uterus occur more frequently at that age than any other, and have caused the popular dread. Although hemorrhage is always pathological, its cause cannot always be discovered, and in this dodging period serious hemorrhage may occur and no dangerous condition exist. He would like to believe that cancerous growths had a benign incipency, but cannot go so far. The microscopists make many mistakes in ascribing malignancy to growths removed from the uterus. Dr. Goodell then gave a number of cases, in which experienced microscopists had given prognoses of early fatal termination, based upon the cell-formation of growths removed from the uterus, but these cases had recovered, and showed no evidence of any diseased condition. With regard to the small proportion of cancerous growth following laceration of the cervix uteri, the doctor called attention to the large number of Irishmen using clay pipes, and the small number of lip-cancers, and yet it is universally acknowledged that the use of a clay pipe is the principal cause of such growths.

Blood-letting is practiced very freely in Turkey and the East, and women as a consequence get very stout; such are more liable to profuse hemorrhage at the dodging period.

Dr. Wm. T. Taylor reported a case of

Malarial Poisoning in a New-Born Babe.

We have frequently observed fevers of a malarial type in very young children, in some even during the first year, which were ushered in by a convulsion or other prodrome, without a rigor, as occurs in older persons, and their character is only recognized by a repetition of the attack in a day or two. But the youngest subject of this disease which I have met with is the following case:

Mrs. A. R., during her second pregnancy, was affected with malarial fever; and although she was then residing at the seashore, was obliged to take occasional doses of quinine to control it. She re-

turned to her city residence at the end of the season, but continued using quinine from time to time until the end of her utero-gestation, which was completed in November last, when her babe was born. Her labor was natural and easy, and she had no unfavorable symptoms. The child appeared healthy, was of good color, but was smaller and feebler than her first-born at its birth. As she had a good supply of milk, it soon drew the breast quite vigorously.

About one week after its birth the nurse called my attention to "weak spells" which it had occasionally, accompanied by coldness of the skin, a feeble circulation, and prostration, which continued for fifteen or twenty minutes, and were followed by a clammy perspiration. By the application of heat to the body, and giving it a little brandy and water or other stimulant, it would revive.

I observed that these "spells" had a periodicity, occurring every two or three days; and considering them malarial, I gave the mother quinine and valerianate of iron, which, acting therapeutically through the milk, soon caused the "spells" to cease, and the babe became well and fat. I also gave it small doses of the elixir of cinchona for several weeks.

This child must have contracted this disease whilst in utero through the placental circulation; for being born in a perfectly healthy locality, it was not exposed to any external malarial influence.

When labor began the quinine was stopped, and was not resumed until the condition of the child required it, when it soon showed its anti-periodic action by completely arresting these "weak spells," for now the child is perfectly well.

Dr. R. P. Harris related a case of parallel character, which had occurred some years ago in a malarious neighborhood. The mother was under treatment before labor. The child had chills and fever when quite young, and was treated through the mother.

W. H. H. GITHENS, M. D.,
Secretary.

EDITORIAL DEPARTMENT.

PERISCOPE.

Dietetics in Disease.

Apropos of our editorial on "Diet Cure" (cur. vol., p. 373), we note as valuable, the following remarks on dietetics delivered before the Medical and Chirurgical Faculty of Maryland (*Med. News*, April 26, 1884), by Dr. William Pepper.

Remembering the thoughtful little work, *Health, and How to Promote It*, recently published by the President, Professor McSherry, Dr. Pepper said he was led to hope that some practical remarks upon the subject of dietetics might not be without interest. On reviewing what he had prepared, however, he felt that the title selected was somewhat inappropriate, as he had dwelt more upon the relations of dietetic errors to the production of disease than upon the actual value of diet during

the disease. Although the subject has not always claimed the attention which it merits, yet, on the whole, we must acknowledge that amidst the currents and counter-currents of medical opinion during the past decade there has been a constantly growing appreciation of the value of dietetics; indeed, we may safely assert that it is becoming recognized that in very many conditions of impaired health and actual disease successful treatment depends chiefly or exclusively upon proper diet and regimen. He believed that from a proper study of the wide range and varied character of the morbid symptoms resulting from the gift of food abused, and the wonderful remedial effects of special forms of diet, it would appear that it is in this line more than in any other that the greatest triumphs of therapeutics are to be won in the near future. In estimating the influence of the factors of our physical life upon the development of the

individual or race, too much importance has been attached to climate, and far too little to diet and personal hygiene. For the establishment of the laws of dietetics and hygiene we are concerned only with the average man, not with those exceptional individuals in every community who display the highest physical and intellectual health whilst pursuing courses of life admissibly injurious.

In India and Australia we have seen the experiment of subjecting large numbers of Anglo-Saxons to climatic conditions diametrically opposite to those familiar to that race, and the result seems to be that with suitable diet and regimen its characteristic health and energy will not be impaired. In this country a more complicated experiment is being tried. A nation recruited from all quarters of the globe, a vast territory—wide varieties of soil and climate—the gift of freedom, personal, political, and pecuniary, to be borne by millions heretofore comparative strangers to these blessings. Can we wonder that during the fierce contest to be waged with strange and untried climatic, industrial, and social conditions, many curious effects, physical as well as social, have been developed? The so-called typical American, with his pale, sallow face, and tall, slender figure, full of the irritable restlessness bred of nervous dyspepsia, certainly differs widely from his English, Irish, or German ancestors, and the interesting question arises whether his physical peculiarities are inseparably dependent upon our climatic conditions, or upon other and transient influences. Prof. Pepper stated his deliberate conclusion that it is to the latter conditions almost exclusively that we are to attribute these results. He indicated the abuses of various articles of food and drink which are the undoubted cause of this state of things, and reiterated his opinion that this was the cause of most of the physical peculiarities commonly assigned to the American climate. He believed that with due regard to the conditions, there is no more favorable climate upon earth than our own. He deprecated, too, the excessive share which has been attributed to overwork in the production of many forms of nervous exhaustion. In his own experience, cases really induced by this cause were rare, and in the vast majority an amount of work entirely consistent with long-maintained health is rendered destructive by reckless disregard of the laws of health. It is true that the conditions of our higher forms of work in America are more difficult than in older and better organized communities, but a study of the habits of professional and business men in other countries has convinced him that the important question is really "How to live while working."

If it were possible for all to appreciate correctly their physical condition and capacity at the outset, so as to adapt their method of work to their physical requirements, we should see quite as much or more work done with infinitely fewer instances of (physical) disaster. The velocity and range of a projectile vary directly as the initial power, and inversely as the mass to be moved. In its application to the human body this is a most pregnant truth. To adjust the actual weight of the body to the physical powers of the individual, and to render these innumerable minute processes

as easy and complete as possible, is the aim of dietetics and regimen, and the common-sense policy of every man who aspires to work to the best advantage. The enduring capacity of a man is measured by his weakest organ only. We are able by intelligence and self-restraint to spare this weak spot, and enable ourselves to tax our stronger parts to their full extent. The weak spot is commonly at some point in the assimilative process, but by no means *usually* in the stomach or intestines, or, at least, not manifested there most clearly. Whilst the original cause of the trouble may lie there, it very often shows itself in the subsequent changes, whether interstitial or metabolic. For instance, the absence of well-marked attacks of gout long blinded our eyes to the fact that the gouty diathesis is widely prevalent in this country. It is difficult to define gout, but it seems necessary to include under this head all that large series of cases, with or without marked gastro-intestinal disturbances, in which there is obstruction to and deficiency of the ulterior assimilative changes before the food reaches its final fully digested forms.

He wished to call special attention to the great frequency with which, out of the presence of one or more of the causes, there is gradually evolved the complicated condition to which it is becoming the habit to apply the name of neurasthenia, and which is too often regarded as the result of pure nervous exhaustion from overwork, and therefore requiring simple tonics, rest, and high feeding. Such cases, after they have been brought up to a certain point, require a protracted course of well-ordered regimen, dietetics, and exercise. Of course, one special method of treatment can be applicable only to one special group of cases; but it is the work of the skilled physician to discover to what group any special case belongs, and to select the method of medication best adapted to it. He alluded to the special methods employed by empirics—the system of Pressnitz—and those well-known methods employed at popular spas, the waters of which are totally inert. Although unscientifically employed, these methods do succeed in certain cases which have baffled the ordinary medical resources, and prove that remarkable results may be obtained by a systematic and oftentimes extreme use of the simple agents—rest, exercise, food, drink, and bathing.

He spoke of the remarkable treatment called Schroth's Cure, now practiced at Lindewiese, in Germany, which consists in an artificially-induced attack of continued fever, developed by long-continued abstinence from water (thirty-six to ninety-six hours), and great restriction in diet and violent exercise, alternating with free stimulation. While undoubtedly hurtful in many cases, even this has been known to effect remarkable cures in constitutional syphilis, rheumatism, etc.

He remarked on the revival of the hot-water mania, and said that the truth about it is that there are not a few cases of dyspepsia and lithæmia, of certain types of rheumatism, and gastro-intestinal catarrh, in which this remedy, combined with other simple hygienic measures, is the best cure. While hot water, taken as its advocates advise, is capable of doing harm, it will do good in so far as it discourages the use of tea and coffee. We are advancing towards a time when

for each carefully-diagnosed group of cases there will be a scientifically adapted diet.

In illustration of these views, Prof. Pepper proceeded to give in detail several cases of great interest, in which patients suffering from severe disorders were greatly benefited, chiefly by attention to dietetics. One of his cases was a woman of sixty five, with all the symptoms of advanced fatty degeneration of the heart. Noticing that she had steadily increased in weight during her sickness, and was very fleshy, he put her on a reduced diet, and with proper medication effected entire relief of the symptoms in about nine months, during which time her weight decreased from one hundred and sixty-five to one hundred and forty pounds.

Systematic reduction is to be instituted only when symptoms clearly indicate it. When reasonable reduction of diet fails to produce a marked diminution in the weight, the patient has probably not too much weight. When body weight falls rapidly, even if symptoms subside commensurately, check it early to avoid debility. Care must be taken in reducing weight, lest a marked reduction might favor the development of some latent morbid tendency, such as tuberculosis, cancer, or scrofula. A reaction has commenced against the indiscriminate stimulation in disease advocated by Todd and his followers. In acute disease, to push stimulants and concentrated food beyond the power of the patient to assimilate, puts an additional burden upon his already weakened system. In chronic diseases, restoration of power, relief of symptoms, etc., can only be accomplished by thoroughly adjusting the diet and hygiene to the altered conditions of the state of nutrition, and then as far as possible directing our remedies to the actual indications.

Clinical Remarks on Dropsy.

Dr. G. G. Roy thus writes in the *Southern Med. Record*, January 20, 1884:

The case I now present you is a typical one of dropsy, and belongs to a class of cases more empirically diagnosed and treated than any I can now call to mind. And why is this? The reason is obvious: Sight is lost of the fact that, pathologically considered, dropsy is not the disease *per se*, but the symptom and result of organic lesion, or disease.

When brought into contact with a case of this sort—too frequently—the plan of the average practitioner in dealing with it is about that of the most unmitigated dropsy quack, with which the world is now flooded. He sees the patient is swollen—it may be local or general; he pronounces, without hesitation, "It is a case of dropsy," and all we have to do "is to get rid of the water;" and this he essays to do—and sometimes succeeds, by the use of active diuretics and purgatives—and he pronounces his patient cured.

Now, gentlemen, I wish to impress this point upon you—and hope you will never forget it—that getting rid of the water, or reducing a dropsy, is *not* curing the disease.

Another fact—of greater importance—I would impress upon you is, that when you have a case of dropsy to deal with there are three vital organs you must carefully and searchingly interrogate before you can properly diagnose and treat it.

These are the liver, heart, and kidneys; in one or more of these you will find the obstruction which dams the blood, from which the effusion or dropsy comes. I have mentioned them in this order because, in our malarial Southern country, the obstruction is in the liver (fortunately for the patient) more frequently than in either of the others.

I would, also, like you to remember that dropsy may be *active*, the result of acute inflammation, or *passive*, the result of chronic or continued obstruction of the veins. In *liver* dropsies you will generally find the swelling in the abdomen; in *cardiac* or *heart* dropsies, in the lower extremities, especially the feet; and in *kidney* dropsies, especially from albuminuria, in the eyelids and face. To an experienced observer, the doughy puffiness of the eyelids and face in this last affection is almost pathognomonic.

You have a diseased liver, heart, or kidneys, upon which the dropsy depends, and of which it is a *symptom*. Now, what is the rational plan of treatment for its cure? The *dropsy quacks* have learned that drastic purging of the bowels or kidneys will oftentimes reduce a patient so swollen that the integuments of the lower extremities have split or burst—and it is a shame upon the American people to say it, but it is true that this bit of knowledge is daily extending their fraudulent fame, and filling their purses with ill-gotten ducats. But the quack stops here; he can go no further; he does not know whether it is a liver, a heart, or a kidney dropsy, nor does he care—the sooner the dropsy re-accumulates, the sooner his purse is replenished.

But with you, gentlemen, it will not be so—it *must not* be so. Having diagnosed the cause of the dropsy—the organ diseased and its nature—you, too, by the judicious use of purgatives and diuretics, will endeavor to relieve the dropsy; having done this, you will not stop and pronounce your patient cured, but will proceed at once to remove the cause by relieving the obstruction of the veins wherever located, whether it is with the liver, the heart, or the kidneys, and at the same time improve the quality of the blood.

This woman's dropsy evidently comes from obstruction of the portal circulation from a hardened liver, the result of chronic malarial poisoning, and we will place her upon Dr. Alonzo Clark's pill of

R.	Hydr̄g. chlo. mite,	gr. xij.
	Pulv. digitalis,	gr. xij.
	Pulv. scillæ,	gr. xij.
M. ft. pills or capsules No. 12.		
Sig.	One three times daily.	

And every other night a pill of

R.	Elaterium (clutterbucks),	gr. j.
	Ext. jalapæ,	grs. xij.
	Pulv. digitalis,	grs. xij.
	Pulv. scillæ,	grs. xij.
M. ft. pills or capsules No. 12.		

You will omit the pill of the first R. the night this is given.

After we reduce this patient, which we may reasonably hope to do in a week's time, we should address our treatment to the hardened liver, which has obstructed the portal circulation and caused

the dropsy, and for this purpose I have found nothing better than this :

R. Hydrg. bichlorid,	gr. j.
Ammo. murias,	ʒ iij.
Elixir simpl,	q. s. ʒ iv.

M. ft. sol.

Sig. Teaspoonful three times daily in wine-glass of water.

I hope you will remember that, while using this treatment, it is all-important that you should build up the blood with the most soluble ferruginous preparation. If not, you may certainly expect the dropsy to return from the slightest imprudence of diet or temperature.

The liver of the chronic drunkard is peculiarly susceptible to the influences which produce this kind of dropsy; and in these cases I have used Prof. Robley Dunglison's ferro-saline repeatedly with most signal relief. The ferro-saline is a combination of sulphate of magnesia and sulphate of iron.

Transfusion of Blood in Albuminuria.

From the *London Med. Times*, March 15, 1884, we learn that the *Gazette Hebdomadaire*, for January 18, publishes what it regards as a very important paper, bearing this title, read by Dr. Dieulafoy, of the St. Antoine Hospital, at the Hospital Medical Society. He first draws attention to the remarkable fact that the lives of persons dying from hemorrhage have often been saved by the injection of so trifling an amount of blood as 100 or 150 grammes; and he relates a case in point, in which a person dying of an epistaxis which resisted every measure resorted to during 20 days, was at once rescued from danger by the transfusion of 120 grammes of healthy blood. Such a case as this, however, differs from those cases of traumatic hemorrhage (consecutive to operations or to delivery), in which the case is purely accidental; for it is brought about and maintained by an altered condition of the blood, of an ill-defined nature, termed for want of a better name *hemophilia*,—a dyscrasic condition in which perhaps the structure of the small vessels is at fault, but in which the blood is certainly no longer possessed of its normal properties. Life has been saved by transfusion in several cases of this kind, not merely because the blood supplies an additional amount of fuel to an expiring lamp, but because it plays the part of an agent which is to some extent hæmostatic. The addition of so small a quantity of healthy blood serves to modify advantageously the composition and fabrication of the blood that seems to have lost its principal qualities. "In such a case," Dr. Dieulafoy observes, "the infused blood acts, I repeat, as a hæmostatic agent. It is a powerful modifier, rapidly transferring a dyscrasic condition of long date by a special action, the mechanism of which is as yet ill-known, but with a result well calculated to attract attention. All the importance of these facts, which seem to me to dominate the history of transfusion, has not yet been sufficiently brought out. A closer investigation of them has led me to ask, like many others for that matter, whether there is not reason for the application of transfusion to some dyscrasic conditions in which alterations in the blood seem to play an important part. May not dyscrasic hemorrhages, uræmia, and Bright's

disease, diabetes and acetonaemia, the paroxysm of gout and rheumatism, derive benefit from this modifying agent, the effects of which we are as yet ignorant of, because they have not been sufficiently investigated?" In order to render an extended therapeutic application of transfusion possible, Dr. Dieulafoy has contrived an apparatus, which he believes will much simplify and facilitate its application. An illustrated description of it, as laid before the Académie de Médecine, is contained in the same number of the *Gazette Hebdomadaire*. In the present paper he relates three cases of Bright's disease in which transfusion was performed; but he admits that nothing conclusive can be decided from them. They however establish the innocuity with which injections of 120 grammes of blood may be performed, even in the later stages of Bright's disease; and also the temporary amelioration that may be obtained, even when the lesions are of the most formidable character.

Operation In Spinal Caries.

Dr. Richard Davy thus writes in the *London Medical Times*, January 19, 1884:

I have read Mr. Treves' paper on "The Direct Treatment of Spinal Caries by Operation," brought before the Royal Medical and Chirurgical Society of London, and can endorse his views to a practical extent, as evidenced by my own practice. From my own surgical experience, and from facts observed at the mortuary, I have learnt to view with slight favor the opening of abscesses in connection with vertebral disease, and have taught that, as a rule, any such interference is fraught with inconveniences both to the patient and surgeon.

A man, æt. 38, was admitted into the Westminster Hospital in May, 1879, suffering from diseased lumbar vertebrae with deformity, associated with a large psoas abscess, which had burst below Poupart's ligament on the right thigh. I wished to ascertain, by making a dependent opening in his loin, if good drainage might not assist in promoting a cure.

On May 29, 1879, having had a silver probe specially made, twenty inches long, I passed it through the abscess opening in Scarpa's triangle, along the sheath of the psoas muscle, towards the right loin with care; and without any difficulty I could feel exposed bone. Having withdrawn the probe, and made a short bend at its point (45°), I reintroduced it along the psoas sheath, until it touched the top of the abscess-wall, directing the point of the probe towards the loin. I then cut down on it, introduced my forefinger through the lumbar wound into the abscess sac, felt the denuded bone, and washed out the detritus with a stream of warm water, through the tunnel from the right groin to the loin. The lumbar wound was maintained open by a drainage anchor. The patient was discharged with both wounds healed; but the old abscess-opening in the groin seemed inclined to re-open on his assuming the erect posture. When compulsorily pressed to open a psoas abscess, I have always chosen the loin as a point of selection; being unable to see why a lumbar abscess should have the honor of exemption from ordinary surgical custom; viz., a large dependent opening for the promotion of cleanliness and good drainage.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT MEDICAL LITERATURE.

—The applications of iodoform in dental surgery are set forth by Dr. C. F. W. Bödecker in a reprint from the *Independent Practitioner*.

—An urgent note of warning against the opium habit is sounded by Dr. A. P. Meylert, of New York city, in an address published by G. P. Putnam's Sons. The author says :

It should be understood that opium habituation means death—mental, moral, and physical. Every one who cannot instantly drop it, is drifting towards destruction. He does not see it perhaps. Like the Rhine boatman gazing at the vision of beauty upon the cliff above him, he is swiftly dashed upon the rocks below.

—"An Address on the Duality of Ma'sn Being," by Dr. G. R. Scriven, of Hanging Rock, Ohio, appears to us considerably behind the age. Nothing can be more contrary to the doctrines of modern science than such a statement as this :

All our studies in physiology and pathology point back to a period in the history of the race, when man was absolutely perfect in all the elements and parts of his being; when he was without the taint of disease, and hence could not have been subject to sickness or death—a period when to the physiologist he was a model of absolute physical perfection.

The writer of that could not have read any works later than the eighteenth century.

BOOK NOTICES.

Clinical Lectures on Mental Diseases. By T. S. Clouston, M. D. 8vo., pp. 550. H. C. Lea's Son & Co.

The author of this volume has long ranked among the most eminent Scottish alienists, and the English edition has met with a ready reception. The revision for the American market has been made by Dr. C. F. Folsom, of Boston, who has added an appendix on the laws of the United States and the several states regarding the custody of the insane.

The text is in the form of a series of lectures, nineteen in number, and is illustrated with a number of handsomely executed color plates. The classification is peculiar, mental diseases being included in groups characterized by mental depression, mental exaltation, states of alternation or periodicity, states of delusion, of enfeeblement, of stupor, and of defective inhibition. Besides these, lectures are devoted to such definite diseases as general paralysis, epileptic, traumatic, syphilitic, and alcoholic insanity, that brought

about by masturbation, the puerperal state, adolescence, senility, etc. The last lecture is on the medico-legal and medico-social duties of physicians with relation to the insane. We have been much pleased with the work, and regard it as a treatise of great merit.

Diagnosis and Treatment of Diseases of the Heart.

By Constantine Paul. Translated from the French. New York, Wm. Wood & Co.

The French are celebrated for accuracy in diagnosis and vagueness in therapeutics, and this volume is a fair representative of their school. It is written (or translated) with less ease of style than most French writers display, but presents a large assemblage of useful facts. It is a member of Wood's Library of Standard Medical Authors, and will be found a valued addition to it.

Post-Nasal Catarrh and Diseases of the Nose Causing Deafness. By Edward Woakes, M. D. 8vo., pp. 224. Price, \$1.50. P. Blakiston, Son & Co.

The author of this volume is a well-known aural surgeon in London, and his volume is a practical and useful treatise. It treats of catarrh generally, both acute and chronic, its etiology, hygienic management, diagnosis, and treatment. This is followed by chapters on chronic pharyngitis, hypertrophy of the tonsils, stenosis of the nasal fossæ, and the relation of the latter to diseases of the ear and deafness. A few illustrations accompany the text, and the manufacture of the volume is throughout satisfactory.

The Physician's Combined Day-book and Ledger.

By H. T. Hanks, M. D. Half-bound Russian, \$4.50 and \$5.50. For sale by J. H. Vail & Co., New York city.

In the announcement of this blank book, it is correctly observed that the least possible expenditure of time in keeping the accounts legibly and correctly, and the use of as little space as is consistent with accuracy and specification, are the two important factors of a physician's day-book or ledger. The author claims to have arranged in this book the most exact and labor-saving system of book-keeping yet devised for the use of a physician. While his plan is a simple one, it is, in our opinion, too simple. It is, in fact, nothing but the debit and credit columns of the ordinary single entry day-book running across the page instead of down it. There are no columns for totals, for balances brought forward, or for other items of this kind, essential to an accurate set of books. It impresses us that in the desire to simplify, the author has sacrificed convenience and completeness. We can speak favorably of the manufacture of the book, ruling, paper, etc.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, - - -	2.50
Reporter and Compendium. - - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - - -	6.25
Reporter, Comp. and Pocket Record, - - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

AN OBSTETRIC CASE

(Price, \$15.00),

OR

AN ELECTRIC BATTERY

(Price, \$25.00),

AS PREMIUMS.

Any subscriber to the REPORTER who will send us before the 1st of July the names of *three* new subscribers with their yearly subscriptions (\$15) or *five* new subscribers with \$25.00, will receive, for the three, an Obstetric Case complete, and for the five, an Electric Medical Battery complete. They are new, of the best make, and of guaranteed excellence. The new subscribers will receive the REPORTER *free* from the date of the remittance until July 1st next.

Address DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA, PA.

GONORRHOEA.

At its meeting on April 23, the Philadelphia County Medical Society was regaled with a most instructive discussion on the subject of Gonorrhœa. This disease receives so little thought from the profession, its treatment is of such a routine nature, and so many false and damaging statements are published concerning it, that the discussion in question assumes very great importance.

The opening remarks were made by Dr. J. William White, who, since the death of Dr. Maury, has had annually more experience in venereal diseases than any other man in Philadelphia.

The two most important points that he made were, 1. That you cannot abort true gonorrhœa; 2. That it is not by any means the simple, harmless disease that it is usually considered to be.

The first point is an exceedingly important one, in consideration of the numerous papers on the abortive treatment of gonorrhœa which have been published recently, more especially in New York. Dr. White considers it impossible to cure a case of genuine acute inflammatory urethritis in less than from three weeks to one month. He recognizes a variety of the disease, to which he gives the term "irritative or abortive," and which will be found in about five or six cases out of every twenty or thirty. The initial symptoms here are the same as in true gonorrhœa; there is the same redness of the meatus, the throbbing of the penis, ardor urinæ, and mayhap some discharge, coming on after sexual intercourse. If left to itself, this abortive type of the disease will get well in a few days; and it is in these cases, no doubt, that the abortive treatment of gonorrhœa has gained its notoriety.

That it is by no means a simple and trifling complaint was fully evidenced by the cases reported. One of a healthy, hearty man, who contracted his first gonorrhœa; the inflammation extended until a severe peritonitis ensued, and the man died in thirty-six hours. Dr. Forbes related a case, also in a healthy man, wherein the inflammation traveled up the left ureter, and reaching the kidney, the man died of nephritis, when, upon post-mortem, the left kidney was found to

weigh sixteen ounces, and it was riddled by sixteen abscesses. Other cases were cited which proved, in most unmistakable terms, that gonorrhœa is a disease to be dreaded; and we feel sure that every man who was present at this meeting will hereafter regard the disease with much more fear than he has hitherto been accustomed to entertain for it.

Another point of vital moment upon which Dr. White very strongly insisted, was that gonorrhœa was not a specific disease; that is to say (and it is well to have a very clear understanding of what he means by this term), that the fact of a man having gonorrhœa is not proof positive that he has indulged in connection with a woman who has the disease. Any muco-purulent discharge, that is, any discharge in the vagina which has pus in it, may, according to Dr. White, produce a genuine gonorrhœa; it is not necessary to have a pre-existing gonorrhœa. Some men hold that simple acrid vaginal or uterine discharges can produce urethritis or gonorrhœa; their opponents have confronted them with the immunity of married men, since the majority of married women have some acrid vaginal or uterine discharge. Ricord has endeavored to meet this objection with his theory of acclimation, but Dr. White goes further, and says that in his opinion the absence of pus from these discharges is the cause of the immunity, since the discharge must be purulent to be infectious. Hence, in Dr. White's experience, a much larger proportion of cases of gonorrhœa are contracted from mistresses and from what might be called promiscuous intercourse, rather than from prostitutes, who have learned scrupulous cleanliness as a matter of business.

Dr. White was asked by Dr. Shakespeare how he reconciled this teaching with the fact that very often there was an erosion or ulceration of the os or cervix uteri in the woman, discharging pus, and yet the husband failed to contract gonorrhœa. Dr. White was compelled to admit that this was the strongest argument that could be raised against his theory, and it was not satisfactorily answered. While it is, as we all can easily see, of the utmost importance to the welfare and hap-

piness of families to know whether gonorrhœa is or is not a specific disease, yet we must conclude that the matter is still doubtful. The fact that comparatively few cases are contracted from prostitutes, because they have learned habits of great cleanliness, is not an argument against its specificity; for this very cleanliness would remove the specific poison of gonorrhœa, as it would the specific poison of any other disease. Cases such as we sometimes see reported in our journals, where the disease has been contracted from dry gonorrhœal discharge lying dormant on the pants or the shirt or on a rag, and subsequently conveying the disease to an innocent party, Dr. White receives with a great many grains of salt, inclining to regard them as fabrications to hide the true origin of the disease.

Therefore, we would say in conclusion that the non-specificity of the disease is not yet proven, but that two very important points have been elicited by this discussion:

1. The impossibility of aborting the disease; and,
2. The imminent dangers to life it may entail.

Dr. White promises to talk about the treatment of gonorrhœa on a future evening.

ON DRUGGING FEMALES.

Two cases have lately received considerable attention and a great deal of sympathy in the public papers, which call for comment on the part of medical journals. One occurred in Pennsylvania and one in New Jersey, but the details as related by the victims (?) were strikingly alike. In each an alleged innocent young girl was asked into a saloon to take a glass of soda-water. This she swallowed as natural, and nothing more; but owing to the fluid being "drugged," she immediately lost her senses, passed into a state of complete unconsciousness, and when she recovered, found that her male companion had, as one of the girls curiously expressed it, "got the better of her."

Now, the public, and especially juries, should be taught that any such story as this is rank nonsense. There is no drug known to medicine which

will have any such effect. One might suggest opium: but no form of that hypnotic would act so promptly, and none could be given to the extent required without involving serious if not fatal results. The smell and sharp acrid taste of chloroform or ether could not be disguised by soda-water, and no one would drink a glass containing either of these ingredients. Strong alcohol in some form would perhaps act as stated; but it could not possibly be so concealed in a glass of soda-water that a person, especially one unaccustomed to its use, would not instantly remark its presence; in fact, we do not believe such a person could swallow such a dose as it would be.

These stories, in fact, belong with those which we once before branded in this journal, where women claimed that a man gave them a newspaper to read or waved a handkerchief in their faces, and they immediately became unconscious from the chloroform on the article! They are the tricks of adepts, or the excuses of willing victims. Whenever they are offered as accusations, the public and the juries should know at once that the accuser was *particeps criminis*, and if anything the more guilty of the two.

PROGRESS OF THE GERM THEORY.

We find in our English exchanges the report of an interesting lecture by Mr. Watson Cheyne on those minute organisms which, by many, are averred to be the exciting causes of diseases. The lecturer stated that the great group commonly called bacteria might most conveniently be subdivided into four classes—1. Micro-cocci (round bodies); 2. Bacteria (small oval or rod-shaped bodies); 3. Bacilli (large rod-shaped bodies); and 4. Spirochaetic and spirilla (rods spirally twisted).

After dwelling on the great variety as well as importance of the various parts played by this great group in the economy of nature, Mr. Cheyne observed that great difference existed among the various bacteria in their behavior towards the human body; some could be injected without causing any injury, others could not grow in the living body, but could develop in dead por-

tions of tissue, and the secretions of wounds, giving rise to poisonous products. The true pathogenic organisms were able to attack the living body and multiply in it; they included the organisms which found entrance through some wound giving rise to the traumatic infective diseases, and others which could obtain entrance without observable wound. Further, certain organisms, such as the *b. anthracis*, were capable of growing outside the body in dead organic substance; while others, such as the *b. tuberculosis*, were apparently only capable of developing in the living organism or under artificial conditions which reproduced, to some degree, those existing in the tissues of warm-blooded animals, though capable of long retaining their vitality in the dry state.

With regard to the traumatic infective diseases, he thought that the most absolute proof had been furnished that the bacteria found in them, and nothing else, were the causes of these diseases. To establish such a proposition, it was necessary that an organism of a definite form and with definite characteristics should always be found in the blood or in the affected part. The blood or the affected part, when inoculated into another animal of the same species, produced the same disease. When the blood or the affected part were inoculated on a suitable soil outside the body, the micro-organisms grew, and must be indefinitely propagated on similar soil. When in this manner the organisms had been separated from the remains of the materials in which they were imbedded, their inoculation in an animal must again produce the same disease, the same organisms being found in the diseased parts.

These conditions had now been fulfilled with regard to anthrax, septicæmia of the mouse, erysipelas, tuberculosis, glanders, and acute pneumonia. With regard to typhoid fever, relapsing fever, cholera, and ague, the evidence was very strong, but not conclusive.

There were a number of prominent physicians and microscopists present, who seemed to accept his conclusions. They are interesting, as this theory may be considered the question of the day.

NOTES AND COMMENTS.

A Peculiar Operation for Vesico-Vaginal Fistula.

In the *Medical Times* for April 12, 1884, Dr. T. Pickering Pick reports a case of vesico-vaginal fistula occurring in a woman aged 25, subsequent to an operation for stone. Several operations had been performed for the relief of the fistula, but without avail, as the orifice would not close. A recto-vaginal fistula subsequently formed. She came under his care in May last. The vesico-vaginal fistula was of very large size, freely admitting three fingers; in fact the whole of the posterior wall of the bladder appeared to be gone. The lower wall of the urethra had also been destroyed, so that no remains of the canal persisted. The edges of the fistula were healed. The recto-vaginal fistula was of small size, large enough to admit a goose-quill, situated about two inches from the anus. The tissues around were dense and cicatricial.

In spite of the unpromising nature of the case, he made an attempt to close a part of the vesico-vaginal fistula, hoping, by a series of operations, to gradually succeed in closing the whole of it. In spite of free lateral incisions, however, the amount of tension on the sutures was so great, owing to the scarcity of tissue, that they speedily gave way, and not the slightest benefit was obtained. She was in a most miserable and desponding condition, emaciated, with a wan and anxious expression, and willing to submit to any operation which would rid her of her constant trouble and annoyance.

Accordingly, on October the 18th, the patient having been placed under the influence of ether, and in the lithotomy position, he dissected up a circular belt of mucous membrane from the inner surface of the labia minora, just within the orifice of the vagina. By this means he laid bare a surface, an inch in depth, completely round the vagina. He introduced a curved pewter tube through the recto-vaginal fistula, from the vagina, so that the end protruded out of the anal orifice. The raw surfaces were now brought together with three deep quilled sutures, and five superficial silver wire sutures, so that the orifice of the vagina was completely closed.

After the operation she suffered considerable pain, but otherwise did well. The quilled sutures were cut on the fourth day, and removed on the sixth. On October 30th (the twelfth day after the operation), she was placed under the influence of ether, and the silver sutures were re-

moved. The tube was also withdrawn from the rectum. The whole of the wound was firmly united.

One other point in connection with the case requires consideration, and that is, whether he did right in performing this operation. It seemed to be impossible to close the large opening which existed, and the only other proceeding which suggested itself was inapplicable in this case, and that was to sew the lower margin of the fistula to the posterior wall of the vagina. She would then have menstruated through her bladder, and, of course, would have been incapable of bearing children, but, no doubt, would have been able to fulfil the duties of married life. This plan has been suggested as a remedy, in these cases of extensive destruction of the posterior wall of the bladder, but was not applicable in this case, because there was no urethra, and, therefore, there would have been no power of retaining the urine. Besides, it would not have dealt with the recto-vaginal fistula. Of course, the proceeding condemns the patient to a life of celibacy, and this had to be explained to her before commencing the operation; so great, however, had been her sufferings during seven years of incontinence of urine, that she willingly consented to anything that was suggested which would rid her of her infirmity.

Pepper's Treatment of Chronic Bright's Disease.

Before his class at the University of Pennsylvania, Dr. William Pepper (*Med. Times*, April 19, 1884,) presented a woman suffering from chronic Bright's disease and chronic lung trouble, and made the following remarks on treatment:

"With this pulmonary trouble and emaciation, I should be unwilling to treat her with such a rigid diet as I should resort to if she were in a better state of nutrition, and were not the subject of chronic lung disease. She will receive a light breakfast and supper, consisting of some form of mush, with cream or milk. Her dinner will consist of meat, fish, or oysters. Between each meal she will be given a glass of milk; egg will be avoided. The form of albumen found in eggs has seemed to me to dispose to an increased excretion of albumen. I prefer to this lean, under-done meats and oysters.

"I propose to give her cod-liver oil and bichloride of mercury. Iodide of potassium, which I should gladly give her, occasionally irritates the kidneys. I therefore prefer to use bichloride of mercury, beginning with a moderate dose and increasing it as the stomach will permit. I shall

commence with one-fiftieth of a grain, slowly increasing to one-twentieth of a grain, immediately after meals. The cod-liver oil will be given during the alkaline stage of digestion, an hour and a half after meals. Iodine will be applied over the left chest as frequently as can be done without producing too much irritation of the skin. The action of the skin will be promoted by daily friction and the rubbing of a little oil into the skin."

Congenital Epulis.

The following case, which, if not unique, is certainly very rare, is reported in the *Brit. Med. Jour.*, April 5, 1884, by Dr. Albert A. Gore:

Mrs. M. J. McC., aged thirty, primipara, was admitted into the hospital on March 5, at 7 a. m., and confined at 3.15 p. m. There was a considerable flooding from a placenta partially attached to the fundus uteri, and a rent in the cervix. Having removed the placenta and checked the immediate hemorrhage, I found, on examining the baby, that the mouth was filled by a bluish-red tumor, which projected between the lips, and was firmly adherent to the lower gum immediately to the right of the mesial line. It had a very peculiar appearance, and precluded all attempts at sucking, but not of swallowing, when a little milk and water were introduced on the left side by means of a spoon. On March 8, I passed a double carbolized silk ligature, from within outwards, through the middle of the tumor, tying it tightly at either side. It came away in two days. A second smaller growth, to the right of the first, was treated in a similar manner on March 17. When this last came away, there was a good deal of bleeding from the gum, which was only arrested by the application of a point of solid silver-nitrate. The infant did very well, and the gum is now (March 24) quite healed.

Adulteration of Mustard.

Dr. Cyrus Edson has submitted to the New York Board of Health a report of his inquiry into the adulteration of mustard. The doctor says he found that certain manufacturers were coloring an adulterated mustard with naphthol yellow, a dangerous explosive compound and violent irritant poison. Samples of the mustards, besides being adulterated with naphthol yellow, contained 18 to 60 per cent. of flour and 6 to 20 per cent. of terra alba. He says that "the peculiar danger of this adulteration is the fact that mustard is relied on cases of poisoning as an emetic, and that the

death of the patient may follow in the event of its failure to act."

Yet what was done with the scoundrels who were convicted of making and selling this perilous stuff?

They were let off, with an admonition not to do so any more!

Probably they were big men in their ward, and controlled several dozen votes!

The Insanity of Puberty.

The *N. Y. Med. Jour.*, April 5, 1884, tells us that Ball ("L'Encéphale," Jan., Feb., 1884) expresses his opinion respecting the reason for the occurrence of insanity at the age of puberty as follows: The reflex phenomena, which play so prominent a part in grown men, attain the maximum of their development in the child, as Maudsley has pertinently remarked. The majority of intellectual and moral operations performed during the first years of life are sensory and motor reflexes. Automatism plays an immense part during this period of development; and it is only by degrees that individual action is developed, which is sustained by judgment, experience, and volition. Puberty is therefore the epoch at which the greatest psychological transitions take place, and at which the mind is particularly susceptible to the inroads of mental disease. The unfavorable prognosis is, moreover, attributable to the mental arrest which is liable to arise from insanity occurring at this period.

Active Interference in the Management of Abortion.

A recent number of the *Zeitschrift für Geburtshilfe und Gynäkologie* contains an article by Dr. H. Spöndly, of Zürich, on the above subject. The interference which he recommends is simply that, in every case of abortion, the medical attendant should take care that nothing is left in the uterus, should completely remove placenta and membranes; and that in every case of threatened abortion, where the hemorrhage is profuse, and does not yield to treatment, the uterus should be emptied as soon as possible. The expulsion of the placenta should not be left to nature. In this recommendation there is of course nothing novel, nor has Dr. Spöndly any new instrument, or method of effecting the desired end. The main importance and interest of the paper is in the fact, that the author gives a series of fifty-three cases in which he acted on the principles which he lays down, and with uniformly good results.

SPECIAL REPORT.

OPHTHALMOLOGY.—NO. XVII.

BY C. S. TURNBULL, M. D.,
Oculist to the German Hospital, Philadelphia.

(Concluded from page 574.)

Every one has met with cases of iritis in which atropine does not seem to act promptly and satisfactorily, possibly because an increased tension prevents its entrance, or possibly because of the extreme vascularity of the iris, which I regard as the more probable.

In such cases, instead of making paracentesis or abstracting blood, I instil once a day a few drops of a four-grain solution of eserine. In fact, the habit of distilling eserine once a day in iritic cases has become a routine practice, the patient using the mydriatic in the ordinary manner. Iritis is the only disease in which I employ a mydriatic as the fundamental remedy. In more than one case I have seen adhesions let go under the combined action of the myotic and mydriatic, that had resisted the latter alone. In my judgment, eserine is the remedy *par excellence* in corneal affections. In cases in which mydriasis is necessary, this latter can be produced perfectly, and still the specific effects of the myotic kept up. This is beautifully illustrated in suppurative inflammation after cataract operations, formerly so successfully treated by heat and atropine.

Discussion which followed the reading of this paper:

Dr. McKay said that some years ago he became interested in article written by Dr. Seeley, and published in one of the western journals, in which the use of the yellow oxide of mercury was spoken of very highly. Since that time he had resorted to its use in nearly all cases in which an astringent has been considered desirable in conjunctival troubles, and so far had been very favorably impressed with its effects.

Dr. Gruening said, with reference to the alternate use of mydriatics and myotics for breaking up adhesions, that the method was not quite new. He had seen it resorted to in Paris in 1868. With regard to eserine in iritis, that was something entirely new, and he should regard it as a most dangerous practice. He could produce iritis with eserine at any time in a healthy eye, and also in a diseased eye. His experience had been that iritis was aggravated by eserine. He had used eserine after cataract operations, and had set up iritis. In cases of suppurative keratitis he had ceased to employ eserine completely.

Knapp said, with reference to the use of eserine and atropine, that eserine is apt to produce iritis, and may even be injurious after iridectomy for glaucoma. But there are some forms of iritis, especially the serous variety, where the alternate use of the two remedies is of advantage. Again, in plastic iritis, when there is increase of tension which produces intense pain, the patient sometimes is considerably relieved by the instillation of a drop of eserine.

Seeley said he wished to correct what seems to have been an erroneous impression. It was not the alternate use of eserine of which he wished to speak; not at all. He simply spoke of the use of eserine once a day for the purpose of contracting the blood-vessels, so that the atropine could pass through the corneal tissue more freely. In that way he thought we were able to get up a more free dilatation of the pupil than could be done without the eserine. He had never seen a case in which eserine had produced iritis, and he had used immense quantities of it. He employed it in conjunctival troubles, always in corneal difficulties; once a day cases of iritis which came to the dispensary, of course maintaining mydriasis by the use of atropine.

Knapp had given eserine a faithful trial in corneal inflammation since Thalberg published his observations on keratitis from innunction. He had used it in many cases, and at first thought it controlled this process; but later he had not seen that its beneficial action was in any way constant.

McKay said, that in corneal ulcers it had been his habit recently to use atropine until the inflammation had subsided, and then he used eserine with very good effects, and after such use of eserine he could concur quite fully in what Dr. Seeley had said about that drug.

10. *Treatment of Detachment of the Retina.* By W. F. Mittendorf, M. D., New York, who, during the last three years, has been called upon to treat several cases of very extensive detachment of the retina, occurring in patients that had only one useful eye, the other one being entirely blind or absent.

The good results obtained by the treatment of these eyes, which were practically blind when he saw them first, encourages me to report them today. Although no new remedy or method had been used, it is the combination of the different plans devised for the treatment of this affection, and the mode of administering the remedies, that has led to the success. On account of the uncertainty of the operative measures, these had not been resorted to.

11. *Two Cases of Ectopia Lentis, Congenital Double; one case Non-symmetrical, the other Symmetrical.* By W. S. Little, M. D., Philadelphia.

L. describes two cases of congenital displacement of the lens—a rare ocular deformity, which places the patients in the same condition as those who through accidental or intentional traumatism have no crystalline lenses. One case occurred in the practice of Dr. Little, and the other in that of his friend, Dr. C. S. Turnbull. L.'s case was non-symmetrical, the lenses being displaced upwards and to the left; and in T.'s case both were displaced downward and inward. Superior woodcuts illustrate these typical cases. Convex lenses ("cataract glasses") of 2 to 4" focal distance restored the sight in either case.

12. *"On the Employment of Nitrous Oxide as an Anæsthetic in Ophthalmic Operations."* By George T. Stevens, M. D., New York.

"While the use of nitrous oxide as an anæsthetic is no novelty, its employment has been so largely confined to operations upon the teeth that its merits in other classes of surgical operations have been to some extent overlooked.

"Its more general use in ophthalmic surgery would doubtless be greatly to the advantage of patients and surgeons.

"Laughing-gas, in certain classes of operations, possesses several advantages over all other anæsthetics. It is the least dangerous; its use is not attended with nausea, headache, and other unpleasant symptoms, characteristic of the use of ether or chloroform; and it demands for its administration far less time and trouble than either of these. It is suited for short operations, and in such is quite as effective as either of the more commonly used anæsthetics.

"In brief, my experience has led me to the conviction that nitrous oxide may be employed with advantage in many operations about the eyes. Its use is attended with scarcely any of the inconveniences common to ether and chloroform; it is clean, it does not unfit the patient for immediate examination after operations, it is safe, and instead of requiring a large sacrifice of time on the part of the surgeon, often saves time by enabling him to complete operations more rapidly."

13. *A Contribution to the Operative Treatment of Glaucoma.* By Albert G. Heyl, M. D., Philadelphia, who says: "Not a more brilliant example of the value of the empirical treatment of disease is on record than the history of the application of the iridectomy to the treatment of glaucoma. Originating in what was doubtless the false interpretation of a keen clinical observation, applied

to a disease which even to-day is an unsolved problem, acting in a way which Von Graefe himself could not explain, and which as yet lacks satisfactory explanation, it nevertheless, after twenty years of service, is the main resource in glaucoma. Of course, an operation with such a record must have substantial merit; by this, however, is not meant that the status of the glaucoma iridectomy as a remedial measure is fixed; this can never be until we understand the rationale of its action, and the nature of the disease against which it is used. The practical consequence must be that cases present themselves for treatment where the iridectomy is performed, not because we are persuaded that it is the best possible procedure for the patient, but because we know of nothing better." He describes two distinct conceivable methods of operative treatment which to be appreciated, must be read in full, as carefully detailed as a clinical contribution bearing on the etiology and therapeutics of glaucoma.

14. *Some Additional Remarks on the Theory of the Astigmatic Pencil.* By G. Hay, M. D., Boston.

15. *Four Cases of Sarcoma of the Uveal Tract.*

K. reports four successful cases of enucleation for sarcoma of the uveal tract, all of which go to show the importance of a careful diagnosis and speedy removal of the affected globe. Of the last case he goes on to say, the tumor started from the outer layer of the choroid, as the chorio capillaris was tolerably well preserved in many parts of the surface of the tumor. Although in contact with the sclerotic over a large space, no sarcomatous cells were found in this membrane.

In a paper on the "Diagnosis of Intra-Ocular Sarcomata," Becker says: "Choroidal sarcomata originating in the region of the macula seem from the very beginning to have but little disposition to proliferate in the interior of the eye, but are prone to develop posteriorly in the orbit." That this does not always occur is proved by the above case.

16. *"Case of Ossification of the Choroid."* By Charles J. Kipp, M. D., Newark, N. J.

The eye was removed from a young man, 22 years of age, who was first seen ten years before the eye was enucleated. At that time the eye was free from all signs of irritation. There was an adherent chalky cataract, which, according to statements of the child's parents, was first noticed by them shortly after birth. The iris was atropic. The eye diverged, and had but imperfect perception of light. As the case was hopeless so far as the restoration of sight was concerned, no treatment was advised.

Ten years later the patient was seen again. He was now suffering great pain in the eye. There was much circum-corneal injection. The cornea was clear, the anterior chamber of normal dimensions, and the aqueous clear. The iris was much bulged forward in its central portion, while the pupillary margin was completely fastened to the anterior capsule, and the periphery of the iris was retracted. The pupil was very small, and of the form of a crater. The cataract was as before. The anterior upper ciliary region felt soft to the touch, while at every other part the sclerotic was very hard. The eye was enucleated in the usual way, and the wound healed kindly and quickly.

Examination of the eye showed a very thick deposit of a hard substance (bone) over the whole inner surface of the choroid, reaching to the ciliary body. The bony capsule was perforated at the optic nerve entrance. The retina was detached in the form of a cord. The choroid was thickened. A thick diaphragm extended across the eye, and was adherent to the ciliary body. The lens was in front of and closely connected with this diaphragm. The lens was of bony hardness in parts, but no bony structure could be discovered here. The bony capsule showed the ordinary characteristics of bone. The specimen was presented on account of the very extensive formation of bone, which is certainly not very common; and also because of the youth of the patient from whom the eye was taken. It is doubtful whether there is another case on record in which the formation of bone in the eye occurred so early in life.

17. "*Two Cases in which 'Trituration of the Cortex' was Practiced in Connection with Preliminary Iridectomy to Hasten the Development of Slowly-ripening Cataracts.*" By Samuel Theobald, M. D., Baltimore. "Acting upon the suggestion put forth by Professor Förster, of Breslau, in a paper which appeared in a late number of the *Archives of Ophthalmology*,* I have attempted recently in two cases to hasten the development of cataracts, which were very slowly maturing, by having recourse to the procedure which he has called trituration of the cortex—a kneading or bruising of the anterior cortical layers of the lens by pressure upon the cornea, after iridectomy, and while the anterior chamber is still empty. In the first case the excision of the iris was followed by hemorrhage into the anterior chamber, and this obscured the pupil to such a degree that trituration, which was done

with the angle of a strabismus hook, as recommended by Professor Förster, was very imperfectly performed. In the second, in which the kneading was done with the smooth end of a Bowman's tortoise-shell cataract spoon, that seemed better adapted to the purpose, there was no hemorrhage, and the operation was satisfactorily completed. In the first, the operation was followed by but slight change in the condition of the lens; in the second, however, a very rapid development of the cataract ensued. In each there occurred a sufficient amount of iritis to cause slight but persistent adhesions to form between the iris and lens at the pupillary angles of the coloboma; and in the second case it was found, upon examination by oblique illumination a day or two after the operation, that near the cut edges of the iris the pigment layer had become detached from the muscular coat in a manner which was quite peculiar. That the iris should be more or less bruised, as well as the lens, however carefully the trituration be performed, appears inevitable, and the risk of exciting inflammation in this way seems the chief objection to the procedure. It would appear, however, that Professor Förster has not had serious trouble from this source, as he makes no reference to it in his paper."

Discussions accompanied this paper, and Dr. Gruening said he had performed Förster's operation twice during the last year, and had already given the result of the operation at the April meeting of the New York Ophthalmological Society. The first case was that of a lady upon whom he had operated for cataract in one eye; she had an immature cataract in the other eye, and inquired whether or not something might be done to hasten the ripening of the cataract. Dr. Gruening performed a large iridectomy upward, and with the angle of strabismus hook also trituated the lens, but only in the area of the pupil. The result was that no iritis occurred, and the lens became completely opaque within one week. He extracted the lens three weeks subsequently with a very good result.

The second case was that of an old gentleman, highly myopic in both eyes, with double cataract. The condition of the gentleman for four or five years was very sad; he was gradually losing the power of reading, and he was anxious to retain his position, which entirely depended upon his vision. Dr. Gruening proposed this operation to him, and in March of this year he came to New York, where he performed iridectomy upward, and again trituated the lens, as in the former case, only in the area of the pupil, and in four days

*On the Maturity of Cataract: Its Artificial Ripening, Corelyses, and Extraction of the Anterior Capsule. Vol. x., No. 3, September, 1882

the lens was completely opaque. He has not yet performed cataract operation. But if the patient continued to do well, he should in September remove the cataract. There are certainly cases in which the operation is indicated, and it is attended with great gain." This delicate operation is not to be recommended, as discretion is the better treatment part of valor.

18. "*Vaseline-cerate—A Convenient Basis for Ointments Intended for Application to the Eyelids.*" By Samuel Theobald, M. D., Baltimore.

19. "*A Case of Blindness from Retinal Thrombosis in consequence of Facial Erysipelas.*" By H. Knapp, M. D., New York.

"Only a limited number of cases of blindness in consequence of facial erysipelas is on record. Their symptoms vary considerably. There is a lack of ophthalmoscopic examinations during the first stage of the affection. Not long ago I had the rare opportunity of observing such a case almost from the beginning to the end. The results appearing very remarkable in many respects, I feel justified in bringing them to the notice of the society, so much the more so as I can lay before you a number of ophthalmoscopic drawings representing the different stages of the disease.* The case is as follows:

"Reserving a detailed discussion of this case for a publication in the Archives of Ophthalmology, I restrict myself here to the following remarks:

"1. The blindness was produced by compression of the central retinal veins, both having been directly observed with the ophthalmoscope one day after the occurrence of the rapid, almost sudden loss of sight.

"2. The ophthalmoscopic appearances, observed from beginning to the end, showed no neuroretinitis, but the successive stages of thrombosis.

"The decrease of the swelling of the orbital tissue, or the establishment of collateral circulation from the choroid, permitted the return of a limited flow of blood into the retinal arteries, which, however, being impeded by the blocked veins, led to renewed extravasations, to thrombosis, and shrinkage of the arteries, and finally to atrophy of the optic nerve.

"4. Perivascularitis played no, or only an unimportant part in the pathology of this case.

"5. The white segments in the veins and arteries were white thrombi, not hypertrophy of the walls of the blood-vessels.

"6. The thrombosis was present, in all proba-

bility, also in the orbital veins, but did not, as in other cases, extend to the cerebral sinuses."

20. *Changes in Refraction Resulting from a Blow.* By W. H. Carmalt, M. D., New Haven, Conn., who suggests some interesting queries concerning this peculiar form of traumatism.

21. *A Case of Blepharoplasty according to the British Method.* By E. Gruening, M. D., New York.

He then describes at length a most successful operation for entropion caused by a burn, having transplanted his flap without a pedicle from the left arm of the patient.

Case Illustrating the Difficulty in Recognizing Glaucoma. By Lucien Howe, M. D., Buffalo, New York.

The fact to which he would call attention, he says, is the occasional difficulty of a differential diagnosis of glioma. This is illustrated by the brief outline of a case which is honestly described and is far more instructive than a narration of most successes. He concludes by saying, this is not the first time that a similar error in diagnosis has been reported to this Society. In the "Transactions of 1870," Dr. Allin reports the case of a child from whom he removed both eyes for supposed glioma, and although that diagnosis was confirmed by several colleagues of wide experience, the further examination of the enucleated globes proved that glioma did not exist. The same subject was brought up at the meeting of the Ophthalmological Society of Great Britain and Ireland last October, when Mr. Nettleship presented a paper "On Certain Cases of Destructive Ophthalmitis in Children." In this he pointed out the great difficulty of a differential diagnosis between the results of such inflammations and glioma.

It is to illustrate this difficulty that the present case is reported, realizing that quite as much is learned by failure as by success. Moreover, in view of the constant possibility of error, and also in view of large mortality from glioma in spite of operation; it is questionable whether we are justified in such hasty recourse to enucleation as most writers are accustomed to recommend.

23. *Commotio Retinae: or Some of the Effects of Direct and Indirect Blows to the Eye.* By E. Eugene Holt, M. D., Portland, Me.

Prof. F. Von Arlt, in his work, "Injuries of the Eye, and their Medico-legal Aspect," (translated by Dr. C. S. Turnbull, Philadelphia,) under the head of "Participation of the Retina in Contusion or Concussion of the Bulb," discusses the subject very fully.

*The drawings, executed in chromo-lithography, will appear in the first number of the Thirteenth Volume of the Archives of Ophthalmology.

Dr. Holt does not include it among the bibliography of the subject, but it is referred to in a footnote. The association of pupillary symptoms in these cases leads to the consideration of whether they are due to want of reflex to light or iridoplegic; or if the retina is affected secondarily to the cause that produces the anomalies of the iris; the ciliary muscle and the choroid being affected as well and thus affecting the nutrition of the retina, the pupil being primarily affected by the traumatism, and less sensitive secondarily to influence of light on the retina. A case recently observed, hit with a piece of coal some weeks prior to the patient being seen, had no pupillary symptoms then; but a large white patch down and out from optic nerve; this, under treatment, gradually subsided; a scotoma existed, and gradually became less as the opacity diminished. The pigmented condition at points showed the choroid had been involved, and yet no apparent rupture recognizable. Until the evidence of commotio of the brain and spinal cord is obtained, no solution of continuity existing; the subject of commotio retina, while interesting, is not proved. Arlt agrees with this statement.

24. "*Two Cases of Ophthalmoplegia Externa Associated with Disease of the Optic Nerves, from Brain Tumor, with an Account of the Post-mortem Examination.*" By Chas. Stedman Bull, M. D., New York.

These cases are of peculiar interest not only to the ophthalmologist, but also to the neurologist, as they are carefully worked up.

CORRESPONDENCE.

Thomsonianism—Lobelia.

EDS. MED. AND SURG. REPORTER:

In the 5th of April No. of the REPORTER you refer to Thomsonian practice in the use of lobelia, and intimate that you would accept further statements. I do not think that very much is definitely known about this powerful drug. I have a few indefinite statements I will make, if for no other purpose than to relieve the tediousness of continual sober facts.

Thirty-one years ago just now, I bought out a physician, and entered into practice in a town on the Penobscot Bay, and, as luck would have it, I found Thomsonianism rife in many of the best families all about me. No one claimed to be an educated physician, and even some old women were respected as the administrators of lobelia, "hot crop," cayenne, byberry, etc. There was one physician in an adjoining town, who had a large practice and was highly esteemed by those of that way of thinking, and his visits to my neighborhood were frequent and profitable.

It seemed to be a general idea with this people

that lobelia was quite a harmless agent. It was given in large doses, and, when designed as an emetic, it was preceded and accompanied with soda and hot teas. I often heard of cases of complete prostration and relaxation following its use. This did not seem to frighten them, but, on the contrary, was regarded as a proof of its specific effect, as it was "working through the system." Hence they, in many cases, sought to carry the dosing till the patient "could not lift a finger from the bed." Patients rather boasted that they had themselves taken it to this extent. I was acquainted with a highly nervous young woman who had often been so relieved, but as she has so long remained an invalid, though of excellent constitutional stock, there is reason to believe that this drugging was a harm to her.

It is certain that this mode of practice was damaging to typhoid fever, though the believers in it were blind enough to brag on its success in such cases. Sure it is, that the fever cases under this ablest physician were much more aggravated and fatal than such cases which fell to my lot, or that of regular physicians in general. I was called to one young man just before he died, the mucous membrane of whose mouth looked puffy, as though it had been parboiled. When his friends expressed a wish to send for me, the physician desired delay till he could try one other medicine, which he did, for he said he had one which he had given and known to have been given several times "after persons had breathed their last, and it had brought them to." I saw a child with croupy symptoms, but the next day he was out and the father told me that I need not call again, but if necessary he would send for me. A day or two later, the child being worse, another physician was called, who gave an emetic dose of lobelia, which did not operate, and I was hastily sent for, and arrived in season to see the child die, but not of dyspnoea. I think the child died from the direct prostrating effects of the dose. Indeed, I have reason to believe that many patients were so killed, while the cause of their death was ignorantly attributed to something else. However, the practice of using so much hot stuff acted the part of stimulants, and doubtless did something to avert the tendency to fatal prostration, which otherwise must have been common. Soda, when used, in a measure neutralizes its active principles.

While it is possible some cases may have been saved by this heroic dosing, which milder measures would not have reached, I am positive that many lives were sacrificed by it which a more rational course would have cured.

At one time the physician referred to came into my neighborhood to attend a young woman in confinement. It proved to be a breech presentation, and I was summoned to his assistance, and delivered the lady in good shape, and left her in his care. He gave her nothing to quiet nervousness and procure sleep, though he remained in the house the rest of the night. The patient after a couple of hours complained of some pain. He was called up to see her, and gave her a dose of tincture of lobelia, which set up vomiting, which in turn was followed by convulsions, from which she never recovered. Taking the patient of very ner-

vous temperament, who had had a tedious labor with first child, and who was exhausted for want of food and sleep, the remedy he gave was certainly inopportune, and we can hardly wonder at the result. That she was killed when a different plan would have saved her, is quite certain.

On some constitutions in particular it acts like tobacco, inducing sudden and extreme prostration, while our means to combat this untoward depression are none the best. I have myself suffered great depression from small portions of both these agents. A dose of the latter given me by injection for colic more than twenty-five years ago, so injured my nervous system that I have never recovered from it. Of both these agents, in any considerable doses, I am afraid. Yet I use lobelia in several diseases, particularly in asthma and coughs. Indeed, I know an eminent physician who assured me that he does not consider a cough mixture complete without lobelia. I use it in connection with sanguinaria in the catarrhal croup of children, in which cases it works admirably; and yet I do not know but the benefit of the medicine is due to the sanguinaria, as I have lately seen it highly extolled in such cases.

A frequent practice among the Thomsonians was to get the patient steaming hot with abundant hot teas, hot stones or bottles of hot water in bed, or over burning alcohol in a chair, and then suddenly dash cold water or vinegar over the patient. A stout burly sheriff of my acquaintance was thus got hot over alcohol, when the pretended doctor sent down to the cellar and got a pint of almost ice-cold vinegar, and pulling away the clothes from the patient's bosom, dashed the vinegar in. This instantly gave a spasm to the fist, which "striking out from the shoulder," piled the doctor and his empty vinegar-dish into the corner together, when he was told to "get up, and get out of this as soon as possible."

There is no doubt that lobelia contains valuable properties for some diseases in some constitutions; but as it is, as I believe, a treacherous medicine, without reliable antidotes to its ill effects when they occur, as they often will when it is used in large doses, and as we have so many other better known and more reliable medicines for nearly all the purposes to be accomplished by this, the real sphere of its usefulness narrows down to a few diseases in which only small doses of the remedy are required. This, I believe, is where lobelia must stand in the light of to-day.

Boston, Mass.

E. CHENEY, M. D.

NEWS AND MISCELLANY.

Medical and Chirurgical Faculty of Maryland.

At the eighty-sixth annual meeting held in Baltimore, April 22, 23, 24, and 25, the following papers were read:

"Report on Surgery," by Dr. J. Edwin Michael.
 "The Efficacy of Iodoform in Preventing Uterine Colic and Pelvic Inflammation following the Intra-uterine Application of Nitrate of Silver," by Dr. W. A. B. Sellman.

"Report in Section of Practice," by Dr. A. B. Arnold.

"Some Practical Views on Dietetics in Disease,

or the Relation of Dietetic Errors to Disease," by Dr. William Pepper.

"The use of Ergot in Obstetrics," by Dr. P. C. Williams.

"Report on Materia Medica and Chemistry," by Dr. A. Atkinson.

"The Sanitary Needs of the Poor," by Dr. C. W. Chancellor.

"Some Sanitary Statistics of Baltimore in the Past," by Dr. John Morris.

"Four Cases of Abscess of the Brain," by Dr. J. W. Chambers.

"The Progress of Bacterial Pathology," by Dr. Joseph T. Smith.

"Preventable Blindness," by Dr. Samuel Theobald.

"Removal of Fragments of Iron from the Eye by the Magnet," by Dr. Chisholm.

"Photo-micrography," by Dr. A. G. Hoen.

"The Influence of Lung Retractivity in Pleurisy and Pneumothorax," by Dr. F. Donaldson.

"Brain Localization," by Professor G. Stanley Hall.

"Suicide, with Presentation of Mechanical Means of Restraint," by Dr. J. S. Conrad.

"The Maximum Volume of Blood sent out by the Left Ventricle in a Single Beat, and the Influence of Variations in Venous Pressure, Arterial Pressure, and Pulse-rate upon the Work Done by the Heart," by Drs. W. Howell, and F. Donaldson.

"The Result of Operative Measures for Rectal Cancer—Report of Cases," by Dr. L. McLane Tiffany.

"The Common Sassafras a Potent Drug and a Dangerous Narcotic," by Dr. Charles G. Hill.

"Cases of Reflex Cough, due to Nasal Polypi, with Remarks," by Dr. John N. Mackenzie.

"Some Remarks on a Recent Epidemic of Typhus at Bay View Hospital," by Dr. George B. Reynolds.

"Congenital Anomaly of the Fœtal Heart, consisting of the Absence of one of the Segments of the Mitral Valve in which a Systolic Murmur was Heard Before Birth," by Dr. Eugene F. Cordell.

"On Certain Practical Points in the Pathology, Clinical History, and Treatment of Cancer," by Dr. George H. Rohé.

"Results from the Investigation and Study of Cow-Pox," by Dr. St. George W. Teackle.

The following officers were elected for the ensuing year: Dr. Thomas S. Latimer, President; Drs. John R. Quinan and J. E. Atkinson, Vice-Presidents; Dr. G. Lane Taneyhill, Recording Secretary; Dr. Robert E. Wilson, Assistant Secretary; T. B. Brune, Corresponding Secretary; Dr. W. F. A. Kemp, Treasurer; Dr. Richard Thomas, Reporting Secretary; Drs. Williams, Michael, Stewart, Tiffany, and Lynch, Executive Committee.

Texas State Medical Association.

The sixteenth annual session of this Association was held at Belton, April 22, 23, 24, and 25, when the following papers were read:

"Evolution," by Dr. R. W. Park.

"An Historical Resumé of Medicine," by Dr. A. P. Brown.

"Bimuriate of Quinia with Urea Used Hypodermically," by Dr. R. P. Falley.

"Continued Fever," by Dr. S. H. Stout.

"Mineral Waters of Texas, notably Wootton Wells, Lampasas, and Palo Pinto Springs, Sulphur and Luling Springs, and Sour Wells," by Dr. J. M. Willis.

"Intestinal Parasites in Texas," by Dr. C. M. Ramsdell.

"Hot Water in Heart Failure from Hydrate of Chloral," by Dr. C. R. Johnson.

"Alcohol as a Poison," by Dr. J. C. Milner.

"Animal Ligatures from the Texas Mule-eared Rabbit," by Dr. H. W. Dudley.

"Mulberry Calculus from a Female Child, Aged Four Years," by Dr. J. D. Osborn.

"Mulberry Calculus," by Dr. T. H. Nolt.

"Mulberry Calculus," by Dr. W. H. Brown.

"A Case of Periosteum Grafting," by Dr. C. W. Trueheart.

"Antagonism Between Syphilis and Carcinoma," by Dr. Edward Goldman.

"Near-sightedness Caused by a Carious Molar," by Dr. G. P. Hall.

The following papers were read by title:

"Fibro-Cystic Tumor," "Typho-malarial Fever," "Blood-letting Traits," "Operation Cyclone," "Surgery of the Lying-in Chamber," "Prolonged Vomiting," "Magnesia Sulphas as a Cholagogue." Referred to the Committee on Publication: Dr. W. J. Burt, chairman; Dr. J. E. Daniels, and Dr. J. S. Broils.

The following officers were elected for the ensuing year:

President.—Dr. H. C. Ghent, of Belton.

Vice-Presidents.—Dr. E. P. Becton, of Sulphur Springs; Dr. H. H. Darr, of Caldwell, and Dr. M. Martin Hearne.

Secretary.—Dr. W. J. Burt, of Austin.

Treasurer.—Dr. J. Larendon, of Houston.

The next meeting will be held at Houston, Texas, in April, 1885.

American Medical Association.

The American Medical Association convened in annual session in Washington, May 6th, over 500 members being present. An address of welcome to the members of the Association was delivered by Dr. Garnett, after which a report of the executive committee was read, setting forth the arrangements made for the reception and entertainment of the delegates. Dr. Austin Flint, president of the association, then delivered his annual address, in which, after reviewing the history of the association, he dwelt particularly upon the advance which was constantly being made in medical knowledge. He suggested that a committee on education be appointed to confer with the faculties of schools and colleges in order to secure uniformity in the standard of requirements for matriculation and graduation; also that the title of M. D. be made simply honorary, and that it should not entitle a person to practice. Dr. Flint further recommended that a resolution be adopted specifying with more precision the grounds for refusing co-operation with irregular practitioners. He thought that the assuming of some sectarian name ought to place the practitioner out of the pale of the medical code, and this sentiment was applauded by the listeners. In concluding, the president paid a tribute to the

service of the late Dr. S. D. Gross, of Philadelphia, an ex-president of the association.

After announcement of the meetings of the various State delegations, the association adjourned until the next day.

In the evening, the members of the association, with their wives and other ladies of their families, were given an official reception at the White House.

A full report of the meeting will be given in our next issue.

Arkansas State Medical Society.

The ninth annual session of this Society was held at Little Rock, April 30, May 1 and 2. The following papers were read:

"Concussion of the Spine," by Dr. E. Bentley, U. S. A.

"The Germ Theory in Syphilis," by Dr. W. P. Hart.

"Some Ideas on Antiseptics and Antisepsis," by Dr. R. B. Christian.

"Procidencia Uteri, Attended with Rupture," by Dr. D. C. Ewing.

"The Germ Theory of Malaria," by Dr. W. P. Hart.

"Use of Opium in Congestive Forms of Fever," by Dr. J. J. McAlmont.

"The Management of Dyspepsia," by Dr. T. E. Murrell.

"Congenital Extrophy of Bladder," by Dr. G. W. Hudson.

"Gun-shot Wound of Bladder," by Dr. W. F. Blackburn.

"Laceration of Cervix, Complicating Epithelioma of Same," by Dr. J. T. Jelks.

University of Pennsylvania.

At the annual commencement of the Medical and Dental Departments of the University of Pennsylvania, held in the Academy of Music on Thursday, May 1, 1884, the degree of Doctor of Medicine was conferred upon 103 graduates, and that in Dentistry upon 32.

The degree of LL. D. was conferred upon Professor S. D. Gross, and a portrait of Professor Stillé was presented by Dr. Wm. A. Bachelor, on the part of the graduating class, and was received by Dr. S. Weir Mitchell, Chairman of the Medical Committee of the Board of Trustees. The valedictory address was then delivered by Theodore G. Wormley, M. D., LL. D.

The prizes conferred were as follows: The Henry C. Lea prize of \$100 to George A. Bodamer; a \$50 prize to Edgar H. Steer, for first honor; the Alumni prize of \$50 to Wilmer H. Batt; the Faculty prize of \$50 to Hobart Amory Hare; "Agnew's Surgery," to Edgar Steer; microscope to Albert E. Norton.

An Anti-Vivisection Defeat.

The French Court of Cassation has quashed a judgment obtained some time ago by the proprietress of an hotel near the Sorbonne, awarding damages for disturbance to her trade caused by the howlings of dogs undergoing vivisection at that institution. The Court holds that the physiological experiments in question constitute a

branch of instruction given by the State, and that M. Paul Bert, against whom the judgment was obtained, and other professors of every rank, accomplish by such experiments a public service.

Georgia State Medical Society.

At the thirty-fifth annual session of this society held in Macon, April 16, 17, and 18, the following officers were elected for the ensuing year:

President—Eugene Foster, M. D., of Augusta.

Vice-Presidents—Drs. J. B. Roberts, of Sandersville; and W. D. Bozzell, of Atlanta.

Secretary—Dr. James A. Gray, of Atlanta.

Treasurer—Dr. E. C. Goodrich, of Augusta.

The next meeting will be held in Savannah, on the third Wednesday in April, 1885.

The Power of Health Boards.

A recent suit in a New Jersey court brought up the question whether the Health Board of the city of Paterson had a right to control the thickness of the walls of new buildings, under a charter which gave the power to "regulate dwelling houses." The Court held that this statute only gave the power to regulate houses in order that they might be free from disease. The word "health" was broad enough, it was said, to embrace the idea of safety as well as freedom from disease, but this was not the general meaning of the word, and was not the intent of the Legislature. The powers of the Health Board must, therefore, be confined to sanitary matters.

The University of Moscow.

In this University during 1883 there were altogether 2,799 students, 1,316 of these being medical. The number of professors amounted to 81, 32 of them belonging to the medical faculty. There were also eight *privat doctentes*, almost all of whom belonged to the medical faculty.

Items.

—An apparatus for lighting doctors' gigs or broughams by electricity has been successfully used in England. The Swan light is used, and a portable battery.

—According to recent decisions by the Treasury Department, the duty on effervescent citrate of magnesium is fixed at 25 per cent., and that on carbon battery plates at 20 per cent., ad valorem.

—The Egyptian Government has abrogated the decree instituting a Council of Health, and has established a directorship of sanitary services attached to the Ministry of the Interior, in whose hands such services shall be centralized.

—Dr. Giovanni Paccinini ligated the subclavian artery on a boy, fourteen years of age, on January 5th, in Rome. The operation was done on account of a wound of the left axilla, which involved the artery and vein. The boy was in a satisfactory condition fifteen days afterward.

—The *Gazette Hebdomadaire de Médecine et de Chirurgie* quotes a Rio de Janeiro newspaper to the effect that Dr. Domingos Freire's supposed discovery of the contagium vivum of yellow fever, and of the practicability of preventing the disease by inoculation, are attested thus far by 211 successful inoculations.

—"Coffee essence," an article used for making coffee in some of the cheap coffee-houses of New York city, has been analyzed by order of Dr. Cyrus Edson, of the Sanitary Bureau, and it is said that many specimens have been found to have been grossly adulterated, with dried blood for example, and that the manufacturers will be prosecuted.

—To a recent meeting of the Sheffield Medico-Chirurgical Society, Mr. G. K. Thorpe introduced a patient with an indurated sore at the outer side of the left eyebrow. The chancre had nearly healed. There were secondary symptoms. At the same meeting Dr. Cleaver showed upwards of one hundred lumbricoid worms, which had been passed by a child three years of age within seven days, by the help of *santonin* and *calomel*.

—Dr. E. M. Moore, jr., has elaborated a plan for the proposed Children's Hospital of Rochester, to be built on the shore of Lake Ontario. The edifice, if constructed, will accommodate about thirty patients, and will be used during the summer months for infants who are stricken with cholera infantum and other summer maladies for the relief of which pure air is necessary. The hospital will cost about \$10,000.

—At a recent meeting of the Berlin Medical Society, Professor Virchow showed photographs of a gigantic palm-tree in the island of Cos, under the shade of which Hippocrates is said, by tradition, to have held medical consultations. The tree now stands in the market-place of the town of Cos, on the east side of the island. The branches, which spread over nearly the whole of the market-place, are supported by marble pillars.

OBITUARY NOTICES.

SAMUEL D. GROSS, M. D., LL. D., D. C. L., OXON., LL. D. CANTAB.

Our readers will be pained to learn that this distinguished surgeon has departed from among us, his death having occurred at twenty minutes before one o'clock on Tuesday, May 6.

Samuel D. Gross was a native of this state. His birthplace was near Easton, and the date of his birth July 8, 1805. He was educated at the classical academy, Wilkesbarre, and at the high school, Lawrenceville, N. J. He began his medical studies at an early age under the preceptorship of Dr. J. K. Swift, of Easton, and continued them for nearly two years under the private tuition of the celebrated Professor George McClellan, M. D., of this city. Dr. McClellan, with a number of prominent citizens, was greatly interested in the foundation of Jefferson Medical College, and the future professor whose eloquence was so often to echo from its walls in after years, graduated from that institution in 1828, and at once entered upon practice in this city. The leisure time which every young physician has his full share of, young Dr. Gross employed in translating several standard French and German medical works. But his ability removed him far above the province of the mere translator, and only two years after his graduation he brought out his first original work, a treatise on "Diseases and Injuries of the Bones and Joints." During the year that marked his appearance as an author he removed to Easton, but his residence there was terminated

in 1833 by his election as demonstrator of anatomy in the Medical College of Ohio. Two years later he was chosen professor of pathological anatomy in the Medical Department of the College at Cincinnati, where he delivered the first systematic course of lectures ever given on morbid anatomy in the United States, writing, in the meantime, his second original work, "The Elements of Pathological Anatomy." This, also, was the first production of the kind published in this country.

Prof. Gross' next invitation to a post of important trust and responsibility came from the University of Louisville, where his services were called for in the chair of surgery. For ten years he labored in that institution, stamping upon it indelibly the impress of his professional genius, and left it only to accept the same chair in the University of New York, where he was the successor of the celebrated Dr. Mott. Louisville, however, was determined not to give him up. His former colleagues in that city were eager for his return, and at the end of the first session he went back to the Louisville University and remained there till 1856, when his alma mater summoned him to return as a teacher to the halls whence he had gone forth as a distinguished student. Dr. Gross finally obeyed the summons, and his brilliant record culminated in the labors of the succeeding period of twenty-six years. Shortly after settling in this city, he founded the Philadelphia Pathological Society, of which he was the first president. In 1867 he was elected president of the American Medical Association. Four years later he was chosen chairman of the Teachers' Medical Convention at Washington. In June of the same year he was elected president of the Pennsylvania State Medical Society, and in 1872 he went to Europe; whither he had already made one trip for rest and health. On the occasion of his second visit he went, not as a rising, but still unknown physician, with only a local reputation, but as a master in his science, a surgeon of brilliant success, and an author whose reputation was as wide as civilization. The University of Oxford, while Dr. Gross was in England, held its one thousandth commemoration, and as a feature of that occasion, gracefully complimented the American Faculty of Medicine in conferring upon its distinguished representative the honorary degree of D. C. L. The University of Cambridge in 1880 followed the example of its sister institution by conferring upon Dr. Gross the degree of LL. D., which he had previously received from Jefferson College, and at the recent Tercentennial of the University of Edinburgh, he was granted the honorary degree of LL. D. Honors now came thick and fast, and not the least among them was Dr. Gross' election, in September of 1876, to the presidency of the International Medical Congress, which met in this city. Four years afterwards the eminent surgeon founded the American Surgical Association, which met on the 29th of April at Washington, and of which he was president. In 1882, Dr. Gross organized the American Academy of Surgery; but in the same year, signaled by his bringing out a new edition of his celebrated work on Surgery, which has been translated into several languages, he resigned his professorship at Jefferson College, to the great regret not only of all connected with the institution, but of the gen-

eral public, though he still continued the active practice of his profession.

The work just referred to is the system of surgery which has passed through five editions, and upon which his posthumous fame will probably depend. The work appeared in 1859, and the last edition was brought out in 1882. In 1863 it was translated into Dutch, and has since, as already stated, been translated, as a text-book, into the languages of most of the leading colleges of Europe. Among other works which he wrote or edited are the "American Medical Biography," "A History of the Progress of American Surgery," and "A History of American Medical Literature." Dr. Gross was one of the founders and early presidents of the Kentucky State Medical Society, and has been elected an active or honorary member of the Royal and National Medical Societies of England, Scotland, Austria, Norway, and other European States.

Professor Gross, at the dinner given to him in this city on April 10, 1879, said: "After fifty years of earnest work I find myself still in the harness; but although I have reached that age when most men, tired of the cares of life, seek repose in retirement and abandon themselves to the study of religion, the claims of friendship, or the contemplation of philosophy, my conviction has always been that it is far better for a man to wear out than to rust out. Brain work, study, and persistent application, has been a great comfort to me, as well as a great help; it has enhanced the enjoyment of daily life and added largely to the pleasures of the lecture-room and of authorship; indeed, it will always, I am sure, if wisely regulated, be conducive both to health and longevity. A man who abandons himself to a life of inactivity, after having always been accustomed to work, is practically dead."

CHARLES T. HUNTER, M. D.

Dr. Charles T. Hunter, late Demonstrator of Anatomy in the University of Pennsylvania, died April 28, 1884, aged forty-one years, after a protracted illness of nearly three years. He suffered from blood-poisoning, induced by a dissecting wound. Dr. Hunter was born in North Bloomfield, Trumbull county, Ohio, January 13, 1843. Receiving his preliminary education in New England, he entered the Medical Department of the University of Pennsylvania, graduating in 1868. Upon receiving his degree, he established himself in practice in Philadelphia, having been for some years assistant to the chair of Surgery in the University. He was a member of the College of Physicians, Pathological Society, and the Academy of Natural Sciences, and had been surgeon to the out-patient department of the Pennsylvania Hospital.

He was a most conscientious and diligent laborer in the medical vineyard, and his death is a great loss to the profession, though to him it is a blessing, as he had been a great sufferer during these three long and weary years.

MARRIAGE.

FAGER—MARSHALL.—In Harrisburg, Pa., January 31, 1884, by the Rev. J. A. Melick, C. M. Fager, M. D., and Miss B. B. Marshall, daughter of Dr. R. C. Marshall, West Fairview, Pa.

THE MEDICAL AND SURGICAL REPORTER.

CATARRHAL JAUNDICE.

BY HUGO ENGEL, M. D.,
Of Philadelphia.

The catarrhal inflammation of the mucous membrane of the biliary ducts is a disease comparatively common in our city. While I have heard of cases that were said to have happened at any time of the year, I have myself never seen a case originate, but in the fall; especially, however, during the later and colder half of autumn. Many cases seem to point to exposure to cold and damp as the pathogenic cause of catarrhal jaundice, and I must confess that on looking over the record of my cases, in most of them such an etiology was apparently proved with great clearness. Still, if we admit that acute lobar pneumonia is an infectious, febrile malady, a zymotic disease with a special tendency to the lungs, and if we remember that in a great many cases of croupous inflammation of the lungs, jaundice, at times combined with vomiting, occasionally ushers in and not seldom accompanies the graver disease, we cannot avoid finding many points of similarity. Besides, analogy makes this view still more plausible. We need but think of typhoid fever to acknowledge the truth of my assertion. There the microzymes may be either swallowed with the food or drink, and may thus arrive in the small intestines, or may be inhaled, when they travel along the respiratory passages, until they have established their dangerous residence in the lungs. In one Prager-epidemic, reported by Koch or by Ziemssen, by far the greatest majority of cases of

typhoid fever evinced almost none of the symptoms usually considered characteristic—diarrhœa and similar evidences of an intestinal lesion—but the whole disease seemed to consist of the lung complication, generally met with only in the later stages, and then looked upon as an accidental occurrence, induced by the position of the patient, and called hypostatic congestion, although recent investigations appear to indicate that the time will not be far when hypostatic congestion, as now known, will be erased from the list of diseases, and be only then admitted to exist as such, when *in articulo mortis* an actual stagnation of the circulation, in parts most dependent, is really apt to occur.

But no matter what the pathogenic cause: exposure to cold and damp in an individual, otherwise already not in the best condition of health, evidently is an exciting and more than predisposing element. Glancing at the list of patients who come under my observation, either in clinic, hospital, private, or consultation practice, I find the following: People suffering from the disease either had been working hard, their nutrition not been the very best, their hygienic surroundings leaving much to be desired, or they had been leading a life of dissipation, or had been the victims of mental overwork, or of cares and worry, or had a constitution debilitated by other agencies. But, whatever had brought their health below par, I have not met with a single individual affected with catarrhal jaundice, in whom, beside the direct, exciting cause, there had not existed a predisposition, induced by a lowered standard of health. Even if the patients would not admit such a state, a careful inquiry into

their history left no doubt as to its existence. Certainly I now refer only to catarrhal jaundice as a separate disease by itself.

There may be some who will contend that a lowered state of health predisposes us to any disease. That such is not invariably the case, I need but refer the reader to pneumonia and typhoid fever—two diseases, in my opinion, allied in more than one respect to the malady in question. Pneumonia, as well as typhoid fever, frequently select their victims from just the most vigorous and healthiest class of individuals, while my experience has taught me the opposite to be the case in catarrhal jaundice.

The disease may begin either abruptly or insidiously. A severe chill, followed by high fever, often remitting in character, and sometimes simulating acute malarial fevers, vomiting, and some pain, more frequently a dull ache or a feeling of fullness in the hypogastric region—mostly round the umbilicus—may usher in the malady. Or the patient complains of general malaise; his appetite is waning, a peculiar heaviness and lassitude, an unaccountable weakness, perhaps with some slight fever and headache, a coated tongue and nausea, and an annoying sensation of something wrong in the middle of the abdomen, are the first or prodromic stages of the complaint. And it seems to me as if the more acute initiatory symptoms, the more violent its onset, not only the longer the pathognomonic signs of the disease wait with their appearance, but also the graver is the prognosis *quoad vitam*, as well as regarding the duration of the illness, while the more insidious the beginning, the more rapidly the disease develops itself and the more quickly it runs its milder course.

Whatever the beginning, whether acute and violent or insidious and mild, the following is sooner or later, with variations only as to degree, the further course of the disease: Jaundice, with all its concomitant symptoms, sets in. The pulse becomes slow and full; the skin and the conjunctivæ assume a yellowish tint, from the palest straw and lemon-yellow to—in very grave cases—a dark olive-green; the patient is suffering from itching; the fæces become dry, hard, and white, or in milder cases clay-colored, and the urine, loaded with biliary coloring-matter and other constituents of bile, assumes a dark-brown tint, and the color-test with sulphuric acid reveals the well-known variegated hue. Another test, recently discovered by Fenwick,* is of value not only in diagnosis, but also in prognosis. Fenwick

has found that in persons suffering from jaundice sulpho-cyanide of potassium disappears in the saliva, and that the earlier in the disease, the more thoroughly and the more continuously this salt is absent, the graver the malady; while even when all the other symptoms still are fully developed, the reappearance of sulpho-cyanide of potassium in the saliva is the surest evidence of beginning amelioration. While concerning the cause of this phenomena, and concerning other questions of interest in connection with the fact stated, we must refer to the original, we will mention the test itself.

The quantity of the salt present in healthy saliva is so small, that a quantitative analysis, especially for the practicing physician, is not to be thought of. The best way, therefore, is the following: Normal saliva is condensed one-half, or one-fourth, by evaporation, or diluted, doubled or quadrupled by the addition of distilled water. Then, to these different specimens is added a small quantity of chloride of iron. According to the percentage of sulpho-cyanide of potassium in the saliva, a discoloration—darker or lighter, as the case may be—will then take place, while none ensues when the salt referred to is absent. These test-solutions once inspected, the addition of chloride of iron to suspected saliva will at once reveal the increase or decrease of the sulpho-cyanide of potassium in the latter.

Aside from the symptoms mentioned, there still is another, perhaps always present and differing but in degree. It is the pain in the hypogastric region. It sometimes is very severe, the patient can scarcely breathe, for the stitch or sharp cutting pain in the region mentioned; this pain is then generally associated with decided tenderness at the same place, and on percussion a dullness over it is elicited, and on palpation a round, or oftener oblong, and more or less hard tumor is felt.

The text-books generally teach that the liver is enlarged. It appears to me that this statement is based more upon theory than upon practice. In some cases I found this organ augmented in size, about one inch and a half below the ribs; in one fatal case there was an enormous increase in size; but in most cases I noticed the liver either to be of normal appearance or smaller. If my observation is correct, if no accidental circumstances favored the recurrence, then the liver seems in those cases not to evince a larger area of dullness, in which the gall-bladder is especially increased in volume. I suppose it is superfluous to indicate that the tumor of which I made mention is the enlarged gall-bladder.

* S. Fenwick, Med. Chir. Transact., lxx.

Many cases run an exceedingly mild course, and, I may add, one very rapid. Others, again, drag on for several years, and some of these never recover totally, but die of some intercurrent disease. Then there are cases which end fatally. To judge of a series of 119 cases, most of them clinic and hospital cases, about 60 per cent. recover within two or three months (about 25 within one month, 20 within six weeks, and the remaining fifteen over two and less than three months), perhaps 27 per cent. are exceedingly chronic, lasting from six months to several years, and the remaining 13 per cent. die. But of so many of the second class the final termination is unknown to me, that very little reliance can be placed on these figures. Different are the figures from private practice. Of 46 cases, either seen in consultation or attended at their homes or in my office by me, 34 recovered within two months (15 within four weeks, 11 within six weeks, 8 within from six to eight weeks), 7 recovered within six months (1 within three months, 4 within four months, 1 within five months, and 1 within 25 weeks), three had not recovered within a year (one did so within eighteen months, Carlsbad having cured him; two, who had not been freed of their trouble within about a year, were lost sight of), and two died (one within three months, the other seventeen months later, when nearly cured, of apoplexy).

Treatment has undoubted influence on the course and result of the disease. And it seems to me that many a patient suffering from catarrhal jaundice would much sooner recover from his malady, were it not for the too early, untimely, and wrong use of cholagogues. I believe that few of the not fatal cases would be ever ailing longer from this disease than, say, six to eight weeks, if they were correctly treated, or at least, if they were not treated at all, but let alone. It was a remarkable fact, deduced by me mainly from clinic patients, that those homeopaths, who honestly administer their infinitesimal doses according to their dogma, are more successful in their treatment of these patients, and cause much less injury than the average regular practitioner; while those hermaphrodites of homeopaths, with allopathic doses (using corrosive sublimate, calomel, etc.) cause the greatest mischief, as they employ at the wrong time the most dangerous remedy, without possessing the somewhat counter-acting greater knowledge of the regular physician, who, understanding the pathology of the disease, does at least not fail to have an eye on the kidneys, while the symptom-hunting ignor-

amus concentrates his whole attention on the removal of the bile by the bowels.

While the treatment I have employed is neither original with me, nor infallible, a considerable experience has proven to me that it is the most successful—and never injurious. I have under it never seen a patient become worse whose prognosis was favorable. As there are many points to be elucidated, I will try to be as concise as possible.

If a case has an acute and violent beginning, and the diagnosis can be early made, I administer to the patient a fever-mixture, as, for instance:

R.	Spirit mindereri,	f. $\frac{3}{4}$ v.
	Spirit ætheris nitrosi,	f. $\frac{3}{4}$ j.
	Tinctur. radiceis aconit.,	℥ xxiv.
M.	S.	

Of this, I let the patient take a tablespoonful every three hours in half a tumblerful of sweetened orange-water, lemonade, Selters or Apollinaris water, until the fever has ceased. Occasionally the dose of the aconite has to be diminished. If the patient is very plethoric, if the fever is high, the pulse full and somewhat hard, the face looks flushed, I bleed him at the arm, taking from twelve to sixteen ounces of blood. These cases are rare; I had but once occasion to employ this procedure; the case, though apparently grave, immediately began to improve, and was well within four weeks. If there is much nausea, or even if there is little, but the tongue heavily coated, or if there is occasional vomiting, I administer a tablespoonful of mustard in a bowl of tepid water, or a hypodermic injection of apomorphia. I wish to caution against tartar-emetic, to be used for the same purpose; in my hands it has at least met with bad results. If the fever is intermittent (very, very rare), or remittent (frequently), and above 101°, I prescribe quinine, a few large doses (twenty grains) once every twenty-four hours.

If the case has an insidious beginning, then I put the patient at once upon the same treatment that I employ in the acuter cases after the fever has ceased.

But no matter how the case is ushered in, as soon as I am positive as regards the diagnosis, I order the local application of from six to twelve European (or twenty-four to forty-eight American) leeches. If there is no special point douloureux or local tenderness (if there is, they are applied as near as possible to it), I have the leeches applied in the hypogastric region, just above the umbilicus and slightly more to the right side of it.

The diet consists of milk, beef tea (bouillon), oatmeal gruel (strained), bread soup, and the like,

given at regular intervals. With the bowels or the excretion of the kidneys (save as by the medicine above referred to), I interfere only when necessity demands such a procedure. Either oleum ricini, or Glauber salt answers in such a case the first, and acetate of potash the second purpose.

When the acute symptoms have ceased, or have never been present, then my treatment is as follows: Here I must dwell for one moment upon the pathology of the disease. What is the morbid condition of the patient? We have an inflammation of the mucous membrane, usually beginning in the small intestines at the pylorus, often in the lower segment of the stomach, and extending thence along the ductus choledochus communis into the gall-bladder, and frequently all the way up along the biliary ducts. The mucous membrane inflames, swells. In consequence of this condition the ducts are narrowed (in fatal cases, *i. e.*, fatal from this cause, the ducts become perfectly occluded, and I have seen in more than one case, where the common duct appeared as if pasted tightly shut) and impede the passage of the bile. The severer this inflammation, this swelling, the less has the bile a chance of passing through. We have, therefore, here nothing wrong with the manufacture, the secretion of the bile—that is undisturbed; but the normally secreted bile cannot get out! In consequence of this condition, the secreted bile partly enters the circulation; its pigment is deposited all over, and the urine becomes loaded with it, as it is the function of the kidneys to take this obnoxious substance out of the blood. If the impediment to the outflow of the bile is too great, lasts too long, or is insurmountable, and if the kidneys are not able to relieve the blood of this poisonous substance, then intoxication of the system by bile takes place, and under symptoms of delirium and coma (due to the presence of bile in the blood) death sets in, after the body has been saturated with bile, the blood depositing it all over, so that a deep-green discoloration of the skin and of nearly every organ ensues, and after great emaciation.

Would it be any use in such a case, while the bile-ducts are nearly occluded, to give a cholagogue—a remedy which, like calomel, stimulates the excretion of the bile? If we still more stimulate its excretion, its flow to a place where nature does not want it, as there is at present no outlet, we simply increase the inflammation still more, irritate and cause a greater swelling of the already inflamed and swollen mucous membrane, and interrupt and divert the effort of nature to reduce to a minimum the flow of the bile through

its natural outlet. We must avoid every remedy that would the least stimulate the excretion of the bile. But what shall we do instead?

Assist the effort of nature to rid the blood, and by it the system, of the obnoxious bile by way of the skin and, mainly, of the kidneys. And it is wonderful to note how long the human organism may exist with the common bile-duct nearly impermeable, with every avenue, open for circulation, choked with bile, if only the skin and the kidneys properly perform their duties.

We must, therefore, try to reduce the swelling of the membranes and the inflammation that caused the former. After the leech-bites have healed, I know of no better remedy to achieve this object than by acting on skin and kidneys, as we shall soon see, and by applying a large fly-blister ($\frac{7}{8}$ inch) over the seat of the lesion. Often I apply a second, and sometimes a third blister, always waiting for the skin first to heal, but more frequently after the second or third blister, I have half a drachm of mercurial ointment rubbed into the abdominal wall every day or every second day, certainly taking care not to cause salivation. But it is amazing, the quantity of such an inunction that the skin will gradually absorb in these cases, as well as in others, where absorption is our aim, without bringing about salivation. I am convinced that many a patient of mine has derived incalculable benefit from this treatment.

Then I prescribe two remedies: acetate of potash, one drachm four times daily in a large quantity of water, my usual prescription being:

R. Potassii acetatis, f. ℥ij.
Tinctur. nucis vomic., ℥xlviij.
Glycerin.
Syrup rubi Idari, āā q. s. ad. f. ℥vj.
M. S.

Two teaspoonfuls of this medicine, to which the glycerin and the raspberry syrup are added only to improve the taste of it, and the nux vomica to allay any irritability of the stomach, contain exactly one drachm of the acetate of potash; this dose is administered in a large tumblerful of water (if possible, Apollinaris) four times daily.

Further, I order two teaspoonfuls of Carlsbad salt to be taken every morning on an empty stomach. But to insure the real effect of this almost specific remedy, certain conditions have to be fulfilled. First, for this purpose I never use the effervescing salt; I employ either the imported, genuine, or, with still greater preference, the artificial Carlsbad salt. As it is difficult to dissolve, as it should be taken lukewarm, in a large quantity of water and in a certain manner, I advise my patients as follows: They are to take a goblet

of the size of a large beer-glass; into this they put the two heaped teaspoonfuls of artificial salt, leaving the metal spoon in the glass to prevent it from cracking; then the glass is *slowly* filled with boiling water, and the solution continually stirred. If these last two precautions are not observed, a part of the mixed salt will recrystallize, and not dissolve in the quantity of water prescribed. Then the glass is covered with a saucer, and kept over night in the bedroom of the patient, who in the morning on awakening, say, for sake of illustration, seven o'clock, once more stirs his Carlsbad water, and then drinks the sixth part of it. Ten minutes later he takes the second sixth, and, if he is now able to leave his bed, as most are, he rises, and while washing and dressing himself, he sips the third sixth. Then he goes into his yard, or in inclement weather into the largest and best-aired room in the house, and walking up and down he drinks every ten minutes another sixth, so that within about half an hour the Carlsbad water has been swallowed. The patient must then wait half an hour with his breakfast.

As long as the passages don't weaken the patient, as recognized by the pulse and by his own feelings, the number of the stools from this two-drachm dose of Carlsbad-salt, whether they are two or six, has no importance; the moment they become weakening, a fact rarely noted, the dose is accordingly decreased. It often happens in the beginning, especially in chronic and maltreated (with calomel) cases, that the patient will vomit for the first two, three or four mornings, and also occasionally later; such an occurrence is always followed by the most beneficial result. Nothing but bile, mostly dark green, and coming in clots, is emitted, and both facts are alike remarkable—the excessive quantity of bile thus thrown up, and the great relief ensuing; the tongue at once becoming clean and moist, and the appetite returning, the pain in the hypogastric region diminishing. Within a week, in most cases, the stools commence to assume a greenish tint, which daily increases in intensity; and in the same ratio the yellow discoloration of skin and conjunctivæ gradually recedes, and the urine becomes clearer, and the pain in the abdomen vanishes.

To assist nature still more, I have the patient take a steam-bath every night on going to bed. As one or the other of the younger practitioners may not be familiar with the easiest and cheapest method of procuring such a bath, I will explain my *modus operandi*. The room in which the patient is to take the bath is brought to a temperature of 74°, as determined by the thermometer—to pre-

vent chilling; the patient, perfectly naked, sits on a high cane-seat chair and is totally enveloped in a large blanket, pinned tightly round the neck, his feet resting on the blanket, and the latter covering him and the chair, and the little space within it air-tight. The blanket is so arranged that the open fold is at the back. Under the chair stands a bucket, or a small tub, half filled with cold water. Into this tub or pail gradually, one after another, three half-pieces of "red hot" brick are thrown, and the blanket is at once again folded up. Certainly, as soon as the hot bricks come in contact with the water, a sudden and rapid evolution of steam takes place, which, being confined to the small space within the blanket, soon causes the patient to fall into a most thorough sweat. The first and second time the skin does not respond very actively, but with every day the perspiration increases. If the patient feel uncomfortable—his hands, etc., all being confined within the blanket—the nurse will give him a mouthful or two of cold water to drink, and sponge off his forehead and face with a sponge dipped into cold water. These two procedures give a great relief.

When the patient almost is through with his forced perspiration, one of the attendants takes a hot iron and goes over the bed-sheets with it, so as to warm thoroughly the bed of the sick person. A hot iron wrapped in rags, or a bottle filled with hot water, may be put at the foot of the bed. Then the patient is released from the "sweat-box," and immediately a large bed-sheet, which has been during all this time hanging near a fire, is thrown over him, and he thoroughly dried. Dressing himself in his warmed night-garments, he retires to his warm bed, while the steam-bath apparatus is removed, and the blanket hung out to be aired and dried.

I have been so particular about these directions, first for the reason given above, and then because I wish to impress the reader with the necessity of using the utmost caution that the patient during this procedure does not become chilled. While I have seen the greatest benefit arise from this steam-bath, and improved with it cases that did not seem to yield to any other mode of treatment, I have observed irreparable injury being done for want of the caution alluded to. In one case I am positive that a patient had a relapse and died within twelve days, because, when coming out of the bath and feeling so well, as he had not for many a long day, he had run, "just for the fun of the thing," after a friend out into the cold entry.

When the pain all has ceased, when the fæces have had a green color for a week without interruption, then I give the patient every fifth or sixth day, in the evening, from five to ten grains of blue mass, followed in the morning by the usual dose of Carlsbad salt. Then, *but only then*, mercurial preparations, especially blue mass and calomel, are excellent remedies, and have no small, if not the most, share in ridding the patient of his disease. But never, under any circumstances whatever, should a mercurial preparation be given in this malady in the earlier stages, or at any time before the symptoms, as mentioned, warrant their beneficial administration.

The question regarding stimulants, diet, and tonics, has been often raised. With reference to stimulants, my experience has taught me totally to avoid them in catarrhal jaundice, as they aggravate the disease. They may be indicated in a confirmed drunkard, but there they may be given as well as anything else, as no such patient, with a full-developed case of this illness, will ever survive, and if he does so, he will soon succumb to pneumonia or some form of liver or kidney disease. I have seen four cases of this jaundice in drunkards; three died of the disease, the fourth could have been perhaps said to have recovered from it, when he rapidly died in consequence of sudden cessation of the functions of the kidneys.

The diet I recommended in the beginning of my lines on treatment, I continue all through; but I add later toasted or stale bread, with butter, eggs, broiled meats, and fresh vegetables, especially salad—in general, a tonic regime.

For tonics I have found no special occasion. Usually in an uncomplicated case of catarrhal jaundice with no organic lesions, the appetite rapidly returns and becomes almost ravenous with the permanent reappearance of bile in the stools. But I have been in the habit of administer about that time tonic doses of quinine; sometimes I prescribe the ferrated elixir of cinchona, and let the patient take three grains of Jensen's pepsin in an acidulated mixture three times daily immediately after meals. If the weather permits, outdoor exercise is as beneficial for convalescents in this as in any other disease, though special precautions against dissipation and against exposure to the chilling influence of a cold and damp air should be always insisted upon.

—Dr. Lermoyez, of the St. Louis Hôpital, Paris, recommends the hypodermic injections of ether for the cure of lupus, and reports successful results.

THE TREATMENT OF SOME OF THE EFFECTS OF SEXUAL EXCESSES.

BY JOSEPH L. BAUER, M. D.,
Of Lehighton, Pa.

(Continued from page 582.)

When I first commenced to devote my attention to urethral surgery, I was under the tutelage of a reputable surgeon, who was well skilled in urethrotomy. Whenever a patient presented a gleet discharge, the bulbous bougie was introduced, and a membranous stricture discovered. One thing struck me invariably, namely, that this stricture was always about the same distance from the meatus, and was not necessarily connected with much pain; and additionally, that the distal end of the bulb was usually covered with a discharge. The surgeon, in a post hoc ergo propter hoc reasoning, concluded that this fluid came from the pouch behind the stricture. I was apparently, therefore, as taught by the new surgery, on the right track. But, unfortunately for myself, I have never missed this fold. It was usually at about the same place, and, in fine, my patients got well without disturbing it. Hence, I have endeavored in every way possible to rectify my prejudices, but I can see no reason to change my views expressed in the January 27, No., 1883, of your journal.

I will not occupy the space of your journal with a lengthy resume of cases. My effort has been to show, that inasmuch as the effects of sexual excess are displayed upon the nervous system, we may rely almost solely upon a few remedies to alleviate whatever results ensue. In order, therefore, to appreciate the method I adopt, I will enumerate the remedies as follows:

1. Ergot or ergotine.
2. Bromide of potassium or sodium.
3. Nitrite of sodium.
4. Hydrate of chloral.
5. Elixir of strychnine, iron and calisaya.
6. Tinct. ferri muriatici.
7. Urethral injections of ext. opii aquosi.
8. Urethral suppositories of iodoform.
9. Steel sounds.
10. Suppositories of ext. opii aq. and ext. belladonnæ in the rectum.
11. Ice suppositories.
12. Continued current of electricity.
13. Faradic current of electricity.

Ergot, or ergotine, in conjunction with either bromides, nitrite of sodium, or chloral, has an excellent effect. The former remedy has a special effect upon the blood-supply of the generative tract, as well as upon the depot of sexual force,

the spinal cord. The latter remedies are sedatives and antispasmodics. These medicines are used whenever general nervous conditions are manifested, or where there are any signs of an irritative tendency; for instance, headache, insomnia, flatulence, constipation, nerve twitchings, painful erections, or nocturnal emissions. I usually commence with small doses of the bromides (say ten grains) and increase gradually. The nitrite of sodium is started with two-grain doses, and increased in $\frac{1}{2}$ grain quantities. I have found the latter salt to have had a remarkable effect upon nerve spasm. Some time since it was recommended for angina pectoris, and believing with a celebrated German physician that asthma was a spasm of the diaphragm, I used it in two cases of this disease with permanent success. This tempted me to apply it in the cases under discussion. In a case of a young man, æt. 24, who suffered with frequent nocturnal emissions, the dose was raised to six grains thrice daily, the effect being satisfactory. Strychnine, iron and calisaya, are used when there is general prostration or asthenia. Tinct. of iron when anæmia is present. Urethral injections of ext. opii aquosi, suppositories of iodoform, and the steel sounds, whenever there is great hyperæsthesia of the urethral mucous membrane. Rectal suppositories of opium, belladonna, or ice, whenever there is tenderness of the prostate or symptoms of increased nerve irritation in the prostatic urethra, resulting in nocturnal emissions, painful erection, lascivious dreams, or prostatorrhœa. The continued current of electricity, whenever the remedies suggested above must be aided, or there is a co-existence of partial impotency, depending upon a failure to complete the sexual act, or there is a rapid emission immediately after intromission. The faradic current is used whenever there are symptoms of diminished nerve stimulus resulting in impotency, or where the steel sound may be introduced into the urethra with the bare perception of the patient. The two following cases will illustrate the results of treatment:

Case 1. F. B., of Missouri, called upon me at one o'clock in the morning. He was afraid he would die; well were his fears grounded. He was suffering from palpitation of the heart; indeed, this organ was temporarily an engine—it beat ferociously against the wall of the chest; he could not lie down or sit up; he was suffering from want of air. A rapid examination failed to disclose any organic lesion. I prescribed hydrate of chloral 15 grains, bromide of potassium 20 grains, extract hyoscyamus fl. gttss. iss. per dose,

to be repeated in one hour unless rest ensued. I requested him to call next morning for more careful examination.

Two doses were requisite to produce a comfortable sleep. I made a careful examination of the heart, the result of which was negative. Having a few days previously examined a medical student—a confirmed masturbator, who was suffering from the same cardiac peculiarity, as well as the delusion that modern physiology stood upon an erroneous basis—I directed my attention to his sexual organs. I was assisted by my friend, Dr. C. L. Flannigan, of Minneapolis, Minn. The patient had not had intercourse with his wife for two months previously, though prior to that time his appetite was frequently appeased. He had never had gonorrhœa, nor had he ever masturbated; prior to complete cessation of the marital act, emission occurred immediately after intromission, and seminal ejaculation caused considerable pain in the prostatic urethra; urination was slightly painful; there was pain in the perineum, and tenderness of the prostate gland. Whenever defecation of a hard stool took place, a slight oozing occurred from the urethra. There was constant lumbago; general nervousness, headache, and mental depression. Examination of the urethra was difficult, owing to its extreme sensitiveness. I prescribed bromide of potash, hyoscyamus, and ergot, and introduced a urethral suppository of iodoform daily for five days. By this means I succeeded in alleviating the urethral sensitiveness, so that I could make a more careful examination. A bulbous bougie was introduced into the bladder, and withdrawn. This determined the usual sensitiveness of the prost.-urethra, and a membranous fold $4\frac{1}{2}$ inches from the meatus. I continued the use of the bromides, added thereto suppositories (rectal) of opium and belladonna, and frequently introduced the steel sound. These measures sufficed to accomplish perfect relief.

Case 2. C. D., a youth æt. 20, consulted me for supposed *AUSZEHRUNG* (consumption). He had cough with mucous expectoration; he had a sallow, attenuated appearance; he was constantly losing flesh. An eruption of acne pustulosa, as well as his peculiar facial expression, tempted me to suggest sexual disease. He acknowledged that he suffered from constant nocturnal emissions, sometimes occurring twice in one night. This, of course, tended to make a natural dunce still worse; indeed, a better picture of brainlessness could not be painted. There were general symptoms of nervous excitement, as well as collapse. Auscultation revealed moist râles in the larger

bronchi, but nothing further. I prescribed twenty-five grain doses of potass. bromid., with one and a half drop dose of ext. belladonn. fluidi thrice daily, and suggested a few of the customary hygienic rules. This treatment kept off all emissions for three weeks, and he improved in weight and appearance. Unfortunately a spree followed this improvement, and the old condition returned. I then prescribed two-grain doses of nitrite of sodium, with one and a half drops of belladonna, gradually increased, with rectal suppositories of aqueous extract of opium. This had the desired effect, the patient having but one emission every two (2) weeks. I endeavored to make a urethral examination, but coaxing produced such a diabolical laugh, that I was compelled to desist.

In the *St. Louis Clinical Record*, I have frequently detailed cases illustrative of treatment, and have directed special attention to the use of the several currents of electricity; hence, I will refrain from it here. If I have succeeded in demonstrating once more that these cases can be treated with good effect by the general practitioner, and do not necessitate the purchase of expensive armories, I shall have accomplished the object of this article.

WORK OF WOMEN PHYSICIANS IN ASIA.*

BY MARY H. STINSON, M. D.,
Of Norristown, Pa.

In the brief space of twenty minutes, we can note in the chain of events but a link here and there by which women physicians were drawn into the work in Asia.

We find a missionary society formed in 1799 to assist in increasing an interest in its work for the heathen, and in raising money for the same a woman's missionary society was organized in 1801. With the same object "Cent Societies" among women were active until 1815, when Maternal Associations were established throughout the churches, and flourished until about 1842. The Missionary Society of 1799 emerged into the "American Board of Commissioners of Foreign Missions," early in whose history it began its efforts to reach heathen women through the labors of single women. In 1817, two ladies were teaching among the Indians. Between that date and 1860, 104 were engaged in the same work, and thirty-six were teaching in other places.

All Christian denominations had strong convictions of duty toward the heathen. The Baptist Union Missionary Society was organized in 1815. The Presbyterian Church, in order to carry on and extend its missions, obtained a charter in 1837. It had previously founded two missions in India in 1834 and 1835; another in 1853.

The Methodist Episcopal Church found it necessary, to enable them to hold property and do business legally, to seek a charter, which was granted in 1839. They sent the Rev. J. S. Humphrey, M. D., to Kumaon, India, in 1857.

The American Reformed Church sent the Rev. E. C. Scudder, M. D., to South India in 1855.

The Rev. Edward Chester, M. D., was sent by the Congregationalists to Madura, India, in 1859.

In order to increase the number of medical missionaries in the societies of Great Britain, "A Medical Missionary Society" was organized in 1841 in Edinburgh, under the supervision of the celebrated physician and philosopher, Dr. Abercrombie.

Our first missionaries were ordained ministers of the Gospel. They took their wives and families, located stations, where grew up their dwellings, a place to preach, a school, and an orphanage. The language of the country was acquired, and the Scriptures translated into the vernacular of the country.

Soon it was felt that female teachers were a necessity, and self-sacrificing, earnest Christian women responded to the appeals for teachers.

March the 11th, 1850, there was chartered in Philadelphia "The Woman's Medical College of Pennsylvania," with a board of corporators. A faculty was organized, 52 students matriculated, and the first class of three women graduated as physicians in 1852.

In November, 1851, there was "A Ladies' Medical Missionary Society of Philadelphia," formed with Mrs. Sarah J. Hale as president. But few persons were advanced enough to comprehend for what purpose it was needed.

In 1852, Rev. Dr. Dwight wrote from Constantinople, "It is my present belief that a well-taught female physician in this place would find access to the families of all classes of the people, not excepting the Mohammedans."

In the session of 1853-54, in "The Woman's Medical College of Pa.," under the auspices of "The Ladies' Medical Missionary Society," were two women studying with the purpose of becoming medical missionaries. Emiline Horton and Elizabeth Shattuck were the first women who had

*Read before the Pennsylvania State Medical Society at its meeting in Philadelphia, 1884.

decided upon medical missionary work in Asia. Providential circumstances prevented the first from entering that work. She became Mrs. Dr. Cleveland, and the first resident physician of "The Woman's Hospital of Philadelphia," established in 1860—the first hospital in the world equipped, officered, and managed wholly by energetic, philanthropic women—also the able Professor of Obstetrics in "The Woman's Medical College of Penna.," and the skillful practitioner so well known in this city. Dr. Shattuck was as one born out of due time. The Board of Missions of her church would not take the responsibility of sending her, not yet having realized the possibilities in the work of a woman medical missionary. For an account of her career, death, and a tribute to her worth, see "The College Story," by Prof. Rachel L. Bodley, A. M., M. D., Dean of "The Woman's Medical College."

American women, beginning to comprehend more fully the misery, degradation, slavery of caste, and idolatrous practices, were aroused to fresh zeal in behalf of their heathen sisters, and to a special interest for their education, which led to the formation in New York in 1860 of "The Woman's Union Missionary Society of America for Heathen Lands."

Among the teachers sent to foreign fields was Miss Brittan, who, after a year of careful inspection and study of the situation in Calcutta, opened fresh zenanas and commenced work in 1864 under the name of "The American Zenana Mission." Her plan and work were most admirable. We must quote her in another link.

The suppression of the mutiny of the Sepoys in 1859, the transfer of the government from the East India Company to the direct authority of the British Crown, the building of railroads, the establishment of an improved school system, dispensaries and hospitals with surgeons and staff of assistants, all tended to assist mission operations.

Coincidentally, or providentially, the necessities of the rebellion in our own country caused women, from its one extreme to the other, to pass through scenes and trials that called forth their sympathy, fortitude, and endurance. They became conscious of their power to relieve distress, to comfort the sick, the cast-down, and the sorrowing. Thus there developed an ability to coöperate successfully and to work collectively. Hence, when peace was restored, women were prepared to engage with renewed energy for their oppressed sisters, both at home and abroad. They also felt that they could work more effectually in connection with their several denominational boards of

missions. Therefore, at a meeting of the ladies of the Congregational churches in Boston, January 1, 1868, their "Woman's Board of Foreign Missions" was formed by only a few women full of faith and zeal; and within that month the Board was in active operation. By the 3d of February, \$500 were in its treasury, and the first woman missionary adopted.

"The Woman's Foreign Missionary Society of the Methodist Episcopal Church" was organized in 1869 by seven women, whose subsequent work seems like magic, as now the membership is 90,000.

Dr. Nutting, from Turkey in Asia, when speaking of the women of that country, said: "I am persuaded that in no way can so much be done for their elevation and enlightenment as by sending out among them well-educated, devoutly pious female physicians."

"The Woman's Board of Foreign Missions of the Presbyterian Church" was incorporated in 1870. In 1871 "The Woman's Baptist Foreign Missionary Society" was launched for the support of women missionaries.

These societies are the channels through which the collections of money by the various agencies throughout the length and breadth of the land are gathered for the support of the entire work of women missionaries.

(To be Continued.)

HOSPITAL REPORTS.

PHILADELPHIA POLYCLINIC.

SERVICE OF DR. ARTHUR VAN HARLINGEN,
Professor of Diseases of the Skin.

Reported for the MEDICAL AND SURGICAL REPORTER.

Cases of Scabies Treated by Naphtol.

Since the appearance of his article on the use of naphtol in the treatment of skin diseases,* Dr. Van Harlingen has continued to experiment with naphtol, and to employ it particularly in the treatment of scabies, with increasing satisfaction. The following cases illustrate the employment of naphtol in scabies:

Case 1. P. A. came to the Polyclinic on June 7, 1884, displaying well-marked, though not severe scabies in the usual localities. He had suffered from the affection for three months, but as he was very neat and cleanly in his habits, it had never gained an extensive foothold. He had used a number of remedies without much benefit. He was ordered the following:

R. Naphtol,	℞iv.
Ung. petrolei,	℞j.
M.	

Under the use of this treatment the patient re-

*American Journal of Medical Sciences, October, 1883.

covered rapidly, and was discharged cured within a few weeks. He afterwards came under observation for localized eczema of the back of the hand, but there was no return of the scabies.

Cases 2, 3, 4, and 5 were boys from a public institution in the city, who had been attacked almost simultaneously with scabies. When admitted for treatment they presented the disease in varying degrees of severity, but were all placed upon the same treatment, the following formula being prescribed:

R.	Naphtolis,	3 ss.
	Saponis viridis,	3 iss.
	Axungiae,	3 j.
M.		

Under the use of this, improvement was manifested in every case, but as the applications were in some instances very imperfectly made, while all the boys were removed at an early period to their homes, the final result was not noted. The rapid amelioration, however, and the abatement of the itching and of the inflamed condition of the skin, indicated the value of the remedy.

Case 6. J. M. W., a man of thirty, presented himself at the Polyclinic on February 28, with well-marked scabies of two weeks' duration, occupying the hands and flexures of the elbows, and also the foreskin and penis generally. The skin of the forearms and hands was in a state of acute inflammation, due to some caustic application. In order to allay this inflammation, a lotion of black wash with carbolic acid was ordered to be used over the most inflamed parts, while elsewhere, in localities where the burrows of the itch insect could be most plainly distinguished, the following formula was ordered to be used:

R.	Naphtol,	
	Saponis viridis,	āā 3 iss.
	Adipis,	3 j.
M.		

The dermatitis yielded quickly to the sedative treatment, and the scabies was rapidly cured, but the patient was so pleased with the effect of the naphtol ointment that he substituted it, after some days, for the black wash, and used it for several weeks over the entire surface of the arms. He then returned without any sign of scabies, but with a rough, irritated condition of the skin of the arms, due, probably, to the sapo-viridis contained in the ointment. This ingredient having been removed and a simple ointment containing a drachm of naphtol to the ounce of lard having been substituted, the irritation rapidly subsided, and the patient soon after disappeared, the eruption when he was last seen having almost entirely disappeared.

Case 7. A traveling salesman applied for treatment on March 13 with scabies of six months' standing, for which he had sought relief from various sources in vain, probably because the nature of the disease had not been suspected. The affection was well marked, involving the backs of the hands, flexure of the elbows and inside of the thighs. He was ordered the following:

R.	Naphtolis,	3 j.
	Saponis viridis,	3 iv.
	Adipis,	3 j.
M.		

This ointment the patient applied so effectually

that within two weeks he was entirely cured, a slight eczema only remaining.

The result of the naphtol treatment in these cases has been so happy that Dr. Van Harlingen is led to believe it the best application for the cure of scabies which has yet been brought forward. It has one great advantage over sulphur, the remedy ordinarily employed, in the fact that it has no marked or disagreeable odor.

With regard to the combination of naphtol with sapo viridis, Dr. Van Harlingen considers the latter a useful adjuvant, particularly in thick-skinned persons, and at the beginning of the treatment, because it helps to break open the curricula or burrows in which the itch insect conceals itself, and lays it open to the action of the remedy. But in thin-skinned persons, and where the applications have been made too vigorously, sapo viridis will, at times, tend to arouse slight inflammation, and its use should, therefore, be restricted to the cases and period above mentioned.

Erythema Multiforme.

February and March usually bring a certain number of cases of erythema multiforme, herpes zoster, and purpura, to the clinic. Such cases are not numerous at any time; the statistics of the American Dermatological Association, collected by competent observers all over the United States, and including nearly sixty thousand cases, show a percentage of 1.16 for erythema multiforme, 1.37 for herpes zoster, and .463 per cent. for purpura. Consequently, such cases are rare at our clinics, and therefore deserve some note. The following case is typical of its kind:

The patient, a woman between forty and fifty years of age, presented herself on February 1, displaying an eruption which, from its striking character, had caused her some apprehension, although it gave rise to no bodily discomfort. The lesions, chiefly situated on the extensor surface of the forearms, were papular in character, of the size of a split pea to that of a quarter-dollar, smooth, flat, with a somewhat rectangular outline rising abruptly from the skin without any inflammatory areola, and presented a peculiar dusky, raspberry color. They were usually distinct and quite numerous. Here and there several lesions were observed coalescing into a larger, irregular patch. There were no scales.

A somewhat similar eruption was observed on the face. The eruption was of about four days' duration, and was evidently at its height. The patient described it as coming out almost suddenly while she had her hands in hot water washing clothes. She also declared that it itched, but as there were no marks of scratching, the pruritus could not have been very severe. She was subject to rheumatism, was constipated, and suffered from headache.

The patient was ordered an aperient tonic mixture—the well-known “mistura ferri acida”—composed of sulphate of magnesium, sulphate of iron, sulphuric acid, and infusion of quassia. Nothing was heard from the patient after her first visit until March 28, eight weeks later, when she reappeared with a fresh outbreak of the same eruption. She said that the first eruption had entirely faded away within two weeks of her visit

to the Polyclinic, and had showed no sign of a return until March 26, two days previous to her present appearance. It then began by the appearance of characteristic lesions under the eye, which increased rapidly in numbers and invaded the whole face. The backs of the wrists and hands were also involved, and when examined, showed numerous lesions similar to those described above, but of smaller size, none exceeding a dime in diameter. On this occasion, there was a feeling in the eruption as if the skin had been struck by a bunch of nettles, and a curious elongated lesion was found occupying the line of a scratch an inch or more in length. Loss of appetite, nausea, and general malaise, were among the symptoms. There was some little stiffness about the ankles, but no decided rheumatic symptoms.

The patient was once more placed upon treatment, and soon entirely recovered.

This case has been detailed because the lesions are of such a marked character, especially as regards their lurid color and because it might readily be mistaken for other diseases of a far more serious nature.

Erythema multiforme is usually marked by the variety of its lesions; there may be erythematous patches, vesico-papules, and tubercles. The peculiarities of configuration which the lesions assume have given rise to the terms annulare, iris, and marginatum, according to the shapes assumed by the grouped lesions. Dr. Stelwagon, of this city, reported, a year or two ago, a case where the entire trunk was covered by gyrate and annular forms, giving a wonderful picture of tattooing when viewed from a little distance, the centre of the lesions changing color as involution takes place.

The course of the disease is usually acute, lasting for a few days, at the end of which time it disappears spontaneously, a fact which should be borne in mind when trying new remedies. Erythema multiforme usually attacks the backs of the hands and feet, the arms and legs being the localities commonly invaded. It also shows itself about the face, as in the case described. The subjective symptoms are rarely troublesome. Notwithstanding the angry inflammatory look which the eruption wears, it seldom itches or burns to any extent. Rheumatic pains, digestive disturbance, and the general malaise, as in the case noted, are not unfrequently present, but in many cases the patient's health is quite undisturbed.

The occurrence of the disease in the spring and autumn is a very peculiar circumstance. Its occurrence in connection with rheumatism is also worthy of note. Digestive derangements are, however, never common in the etiology of skin diseases, and to find these in connection with the affection under consideration, is by no means peculiar in this respect.

Pathologically, erythema multiforme is closely allied to herpes zoster, purpura rheumatica, and urticaria, the entire group of diseases being connected in some way with disturbances of the nervous system—in other words, being “angio-neurosis,” or “tropho-neurosis.”

The diagnosis is sometimes a matter of importance, chiefly because erythema multiforme is liable to be mistaken for more serious and annoying

affections. The absence of violent burning or itching sensations will serve to distinguish it from urticaria, the affection to which it bears the closest resemblance. Its color is also darker than that of urticaria, and there is no tendency to the production of wheals. The lesions of urticaria may disappear in an hour or so, while those of E. multiforme are persistent. From papular eczema the treatment and prognosis of which affection is so different, E. multiforme is distinguished by the absence of severe itching, the large size of the papules, and by its place of election. Eczema papulosum rarely occurs confined closely to any one locality. Erythema nodosum is to be distinguished from E. multiforme by the large, rounded, firm tumors or nodes, which are most apt to occur along the line of the tibia.

Those who lay too much stress on “coppery color and absence of itching,” as a diagnostic symptom in syphilitic eruptions, may find both of these to perfection in E. multiforme. The general history and a careful examination of all the lesions will, however, always show the lack of some characteristics of syphilis.

Eczema Genitalium.

Eczema of the genital organs, whether occurring in the male or female, is one of the most distressing skin diseases with which the physician has to deal. The following case of moderate severity shows the method of treatment followed by Dr. Van Harlingen in this class of cases, although each case requires special management, and the treatment suitable for one form of eczema of the genitals may be quite unavailing when the lesions are of a different character.

Margaret McG., sixty-four years of age, a white-haired Irish woman, unmarried, presented herself for treatment on March 18. She had a worried, anxious look, and declared that she had not been able to sleep for weeks on account of an “itch” in the genitalia. On examination, the external genitalia to the interitus vaginae, and the skin over the pubis and the thighs near by, were found to be the seat of well-marked eczema, assuming the erythematous form within, where the mucocutaneous surface was red, dry, and hot looking, and taking on rather more the appearance of eczema sutrum on the skin around, with a fringe of small papules in the neighborhood. There was slight eczema of the lower eyelids, but no sign of eczema elsewhere over the body. The patient presenting no general derangement of the system, and no abnormal discharge from the vagina, a purely local treatment was ordered. She was told to sponge the genitalia with hot water thrice daily, as a preliminary to making the other applications. Taking a small basin filled with water as hot as could be borne by the skin, this was applied by means of a small sponge tied to a stick, the water being dabbed on in small quantities, and the applications being made in rapid succession for five to ten minutes. A jug of boiling water was to be kept at hand, portions to be added from time to time, in order to keep the temperature up to the highest point bearable. It is extraordinary how high a temperature can be borne by these inflamed surfaces; a sponge soaked with such hot water that it cannot be held in the hand, will be readily borne by the mucocutaneous covering of the labia, and will give relief to the itching when

nothing else will. The application of water being finished, the patient was then directed to pour a small quantity of black wash into a saucer, previously shaking it well, and to apply this to the entire diseased surface by means of a linen rag—not a sponge. After the parts had been well bathed, small rags soaked with black wash were to be placed within the vagina, and between the labia, while the cutaneous surfaces of the pubis, groins, and thighs adjacent were to be smeared over with the following ointment:

R. Ung. zinci oxidi.

Ung. petrolei,

aa ̄ ss.

M.

Under this treatment such rapid improvement took place that the patient was enabled to gain a good night's rest after the first day, and within three weeks was so far advanced toward recovery that she inquired at her last visit if any more treatment were necessary. Commonly, however, a more prolonged course of treatment is required, and we may not usually expect to cure cases of this kind without some internal treatment. The affection is to be differentiated from pruritus, which it sometimes accompanies as a secondary affection. Pruritus is a much more stubborn malady.

Clinical Aspects of Cerebral Syphilis.

Read by HORATIO C. WOOD, M. D., Professor of Diseases of the Nervous System in the University of Pennsylvania.

In the present article I propose to say very little in regard to the lesions of cerebral syphilis, only making such allusions as are necessary to the clinical study. So much practical importance attaches to the etiological relations of the disorder, that I shall discuss these at some length.

We do not know why syphilis attacks one portion of the brain rather than another in any individual case; indeed, very rarely can we give any sufficient explanation why the brain is affected at all.

It is naturally to be expected that any cause of ordinary brain inflammation would, when present in a syphilitic person, tend to precipitate a specific cerebral disease. Thus, as thermic fever frequently provokes chronic meningitis, much plausibility attaches to the report of a case in the *Journ. de Méd. et Chir. prat.*, Paris, 1879, p. 291, where the cerebral syphilis is ascribed to a sunstroke. Blows and other traumatisms would, in a similar manner, be supposed to figure largely as exciting causes of brain syphilis; but I have never met with a case having such relations, and reports of them are rare in literature. The only records I have found are the cases reported by Dr. Broadbent, *London Lancet*, 1876, ii., p. 741, and a small collection in Huebner's article on Nervous Syphilis, in Ziemssen's *Encyclopaedia*, xii. 301. I have seen two cases of presumably traumatic spinal syphilis; one in which a polio-myelitis* followed a fall on the ice; and one in which,

after a fall from a cart, and marked spinal concussion, a local myelitis developed. (*Univers. Hosp. Dispen. Service Book*, x. 1875, p. 58.)

Various authorities attach much influence to over-study and other forms of cerebral strain in exciting brain syphilis. Engelstedt is stated to have reported cases having such etiological relations, and Fournier (*La Syphilis du Cerveau*) affirms that he has especially seen the disease in professional men and other persons habitually exercising their brains to excess. Neither in private or public practice have I met with any instance where over-brain-work could be considered a distinct etiological factor, whilst the wards of the Philadelphia Hospital and the roll of the University Dispensary are full of cases occurring in persons who use not at all the modicum of brains nature has endowed them with. So far as my observation goes, cases of brain syphilis in which any exciting cause can be found are very rare.

The inherited diathesis is less prone to manifest itself in the nervous system than in other portions of the body, but it certainly is capable of causing every type of nervous disease that follows infection from impure coition.

As early as 1779, Dr. Jos. Glenck (*Doctrina de Morbis Venereis*, Vienna,) reported a case of a girl, six years old, cured by a mercurial course of an epilepsy of three years' standing, and of other manifestations of hereditary syphilis. Graefe found gummatous tumors in the cerebrum of a child nearly two years old. (*Arch. f. Ophthalm.*, Bd. i., erst. Abth.) Prof. O. Huebner (*Virchow's Archiv.*, Bd. lxxxiv. 269,) details the occurrence of pachymeningitis hemorrhagica in a syphilitic infant under a year old. Dr. Hans Chiari (*Wien. Med. Wochenschrift*, xxxi. 1881, 17,) reports a case in which very pronounced syphilitic degeneration of the brain-vessels was found in a child fourteen months old. Both Dr. Barlow (*Lond. Patholog. Soc. Trans.*, 1877,) and Dr. T. S. Dowse (*The Brain and its Diseases*, vol. i, p. 76,) report cases of nerve syphilis in male infants of fifteen months.

It is a matter of great interest to know how late in life nervous disease from inherited taint may develop. We have, as yet, little light upon the equally interesting and cognate problem as to how far inherited syphilis may produce late in life nervous diseases, whose type is not distinctly specific; but it is probable that even after puberty specific nervous affections may appear for the first time in the unfortunate offspring of syphilitic parents. Mr. Nettleship reports (*Trans. Lond. Path. Soc.*, xxxii. 13) the development of a cerebral gumma in a girl of ten years, and Mr. J. A. Ormerod (*Ibid.*, p. 14) of a tumor of the median nerve (probably gummatous) in a woman of twenty-three, both the subjects of inherited syphilis. Dr. Thos. S. Dowse (*loc. cit.*, p. 71) details a case of cerebral gumma at the age of ten years, and Dr. Saml. Wilks (*Lectures on Dis. of Nerv. Syst.*, Philad., 1878, p. 333) one of epilepsy from inherited taint in a boy of fourteen. Dr. J.

tions upon the arm and the symptoms were peculiarly symmetrical; great coldness of both forearms; excessive sweating of the palms; loss of power, so much more pronounced in the extensors than elsewhere that the patient had been treated for lead-poisoning and great wasting of the extensor muscles. Evidently a symmetrical syphilis chiefly confined to the anterior spinal cornua.

*In this case the man had symmetrical specific skin eruptions.

Hughlings Jackson reports (*Journ. Ment. and Nerv. Diseases*, 1875, p. 516), paraplegia with epilepsy in a boy of eight, hemiplegia in a girl of eighteen, and in the *Brit. Med. Journal*, May 18, 1872, hemiplegia in a woman of twenty-two; the nervous affection in each case being associated with or dependent upon inherited syphilis. Dr. E. Mendel reports (*Archiv. f. Psychiatrie*, Bd. i., 313) a case of a child who had inherited syphilis, and developed in her fifteenth year a maniacal attack with hallucinations.

Some time since, I saw, in an orphan of fourteen, a chronic basal meningitis, and in the absence of any history, gave the fatal prognosis of tubercular disease; but to my astonishment, under the long-continued use of iodide of potassium, complete recovery occurred. No signs of inherited syphilis were perceptible, but the specific nature of the inflammation is, in view of the result, scarcely doubtful; it is probable that in some of the reported cases of alleged recovery from tubercular meningitis, the affection has really been syphilitic.

The relation of inherited syphilis to idiocy appears to be a close one. What role the diathesis has in the production of those cases which are dependent upon arrest of development, we have no way at present of knowing; but that it very frequently causes chronic hydrocephalus seems to be well established. A number of cases have been reported; they have been collected by Dr. E. Mendel, *Archiv f. Psychiatrie*, Bd. i., 309. For a very important paper, see also, Virchow's *Archiv*, Bd. xxxviii., p. 129.

Nervous diseases following acquired syphilitic infection certainly belong to the advanced stages of the disorder. Huebner reports (*Ziemssen's Encyclopedia*, xii. 298, New York edition) a case in which thirty years elapsed between the contraction of the chancre and the nervous explosion. I have seen a similar period of thirty years. Fournier reports intervals of twenty-five years, and thinks from the third to the tenth year is the period of maximum frequency of nerve accidents.

The fact that cerebral syphilis may occur many years after the cessation of all evidence of the diathesis, is one of great practical importance, especially when taken in conjunction with the circumstance that the nervous system is more prone to be attacked when the secondaries have been very light than when the earlier manifestations have been severe. I have repeatedly seen nerve syphilis in persons whose secondaries have been so slight as to have been entirely overlooked or forgotten, and who honestly asserted that they never had had syphilis, although they acknowledged to gonorrhœa or to repeated exposure, and confessed that their asserted exemption was due to good fortune rather than chastity.

To show that my experience is not peculiar, I may be allowed to make the following citations: Dr. Dowse (*The Brain and its Diseases*, London, 1879, vol. i., p. 7.) says, "Often have I had patients totally ignorant of having at any time acquired or experienced the signs or symptoms of syphilis in its primary and secondary stages, yet the sequelæ have been made manifest in many ways; particularly in many of the obscure diseases of the nervous system." Dr. Buzzard (*Syphilitic Nervous Affections*, London, 1874, p. 80,)

reports a case of nervous syphilis where the patient was unconscious of the previous existence of a chancre or of any secondaries. Prof. Riecke also calls attention (*Archiv. f. Psychiatrie*, vii. p. 241,) to the frequency of nervous syphilis in persons who afford no distinct history of secondary symptoms.

This frequent absence of history of specific infection is of great practical importance, and has led me to attach comparatively little weight to the statements of patients. In private practice I usually avoid asking questions which might bring up from the past unpleasant memories, and arrive at the diagnosis by studying the symptoms present.

Although syphilis is most prone to attack the nervous system many years after infection, it would be a fatal mistake to suppose that brain disease may not rapidly follow the occurrence of a chancre. What is the minimum possible intermediate period we do not know, but it is certainly very brief, as is shown by the following cases of this so-called precocious cerebral syphilis. Dr. Alfrik Ljunggrén, of Stockholm, reports (*Archiv. f. Dermatol. und Syphilis*, 1870, ii. p. 155,) the case of H. R., who had a rapidly healed chancre in March, followed in May of the same year by a severe headache, mental confusion, and giddiness. Early in July, H. R. had an epileptic attack, but he was finally cured by active anti-syphilitic treatment. Although the history is not explicit, the nervous symptoms appear to have preceded the development of distinct secondaries other than rheumatic pains.

Davaine is said (Buzzard, *Syphilitic Nervous Affections*, London, 1874,) to have seen paralysis of the portio dura "a month after the first symptoms of constitutional syphilis." Dr. E. Leyden (*Zeitschrift f. Klin Med.*, Bd. v. 165) found advanced specific degeneration of the cerebral arteries in a man who had contracted syphilis one year previously. Dr. R. W. Taylor details a case in which epilepsy occurred five months after the infection (*Journ. Nervous and Mental Dis.*, 1876, p. 38). In the case of M. X., reported by Dr. Ad. Schwarz (*De l'Hémiplégie Syphilitique Précoce*, Inaug. Diss., Paris, 1880), headache came on the fortieth day after the appearance of the primary sore, and a hemiplegia upon the forty-sixth day. S. L. (*Ibid.*) had a paralytic stroke without prodromes six months after the chancre. A. P. L. (*Ibid.*) had an apoplectic attack seven months after the chancre; A. S., one five months after her chancre. In a case which recently occurred in the practice of Dr. A. Sydney Roberts, of this city, the chancre appeared after a period of incubation of twenty-six days, and two months and eight days subsequent to this came the first fit; eight days after the first the second convulsion occurred, with a distinct aura, which preceded by some minutes the unconsciousness. The further details of this case are not germane to the present discussion, which only requires the additional statement that the attack developed into an unmistakable cerebral syphilis with temporary aphasia, and that convalescence was finally secured by active anti-syphilitic treatment. As the first paroxysm came on without warning, whilst the man was fishing in the sun, it is not unwarrantable to suppose that a precocious cere-

bral syphilis was in this case precipitated by exposure to the ordinary causes of sunstroke. This list of cases might be much extended, but it certainly is sufficient to show that cerebral syphilis occurs not very rarely within six months after infection, and may be present in two months.

An interesting observation in this connection is that Dr. Ern. Gaucher (*Revue de Méd.*, 1882, ii., 678) of a spinal syphilis occurring six months after the appearance of a chancre.

Syphilographers are in accord in regard to the existence of two pathological varieties of brain syphilis, whilst some authorities believe in a third form. The most common seat of attack is the membranes; next to these are the brain-vessels; whilst, as already intimated, there is difference of opinion as to whether the disease ever directly affects the brain-tissue. Reasons will be given later on for believing that the brain-substance may suffer violence from syphilis, but I shall first discuss the clinical aspects of specific disease of the membranes.

Disease of Brain Membranes.—Specific affections of the brain membranes very often declare themselves with great suddenness. The records of the disease present case after case in which an apoplectic attack, a convulsive paroxysm, a violent mania, or a paralytic stroke, has been the first detected evidence of syphilitic cerebral disease. On the other hand, in many instances the symptoms come on slowly and successively. Proper treatment, instituted at an early stage, is usually successful, so that a careful study of these prodromes is most important. They are generally such as denote cerebral disturbance; and, although they should excite suspicion, are not diagnostic, except as occurring in connection with a specific history, or under suspicious circumstances.

Headache, slight failure of memory, unwonted slowness of speech, general lassitude, and especially lack of willingness to mental exertion, sleeplessness or excessive somnolence, attacks of momentary giddiness, vertiginous feelings when straining at stool, yelling, or in any way disturbing the cerebral circulation, alteration of disposition—any of these, and *à fortiori*, several of them, occurring in a syphilitic subject, should be the immediate signal of alarm, and lead to the examination of the optic disks, for in some cases the eye-ground will be found altered even during the prodromic stage. Of course, if choked disk be found, the diagnosis becomes practically fixed; but the absence of choked disk is no proof that the patient is not suffering from cerebral syphilis. In regard to the individual prodromic symptoms, my own experience does not lend especial importance to any one of them; although, perhaps, headache is most common. There is one symptom which may occur during the prodromic stage of cerebral syphilis, but is more frequent at a later stage; a symptom which is not absolutely characteristic of the disease, but which, when it occurs in a person who is not hysterical, should give rise to the strongest suspicion. I refer to the occurrence of repeated, partial, passing palsies. A momentary weakness of one arm, a slight drawing of the face disappearing in a few hours, a temporary dragging of the toe, a partial aphasia which appears and disappears, a squint which to-morrow leaves

no trace, may be due to a non-specific brain tumor, to miliary cerebral aneurisms, or to some other non-specific affection: but in the great majority of cases where such phenomena occur repeatedly, the patient is suffering from syphilis or hysteria.

The first type or variety of the fully-formed syphilitic meningeal disease to which attention is here directed, is that of an *acute meningitis*. I am much inclined to doubt whether an acute syphilitic meningitis can ever develop as a primary lesion—whether it must not always be preceded by a chronic meningitis or by the formation of a gummatous tumor; but it is very certain that acute meningitis may develop, when there have been no apparent symptoms, and may, therefore, seem to be abrupt in its onset. Some years ago I saw, in consultation, a man who, in the midst of apparent health, was attacked by violent meningeal convulsions, with distinct evidences of acute meningitis. He was apparently saved from death by very heroic venesection, but after his return to consciousness developed very rapidly a partial hemiplegia, showing that a latent gumma had probably preceded the acute attack. On the other hand, an acute attack is liable at any time to supervene upon a chronic syphilitic meningitis. At the University Hospital Dispensary I once diagnosed chronic cerebral syphilis in a patient who the next day was seized with violent delirium, with convulsions and typical evidences of acute meningitis, and died four or five days afterwards. At the autopsy an acute meningitis was found to have been engrafted on a chronic specific lesion of a similar character. In the case reported by Dr. Gamel (*Tumeurs Gommeuses du Cerveau*, Inaug. Diss., Montpellier, 1875), in which intense headache, fever, and delirium, came on abruptly in an old syphilitic subject, and ended in general palsy and death, the symptoms were found to depend upon an acute meningitis, secondary to a large gumma.

In this connection may well be cited the observation of Dr. Molinier (*Revue Méd. de Toulouse*, xiv., 1880, 341), in which violent delirium, convulsions, and coma occurred suddenly. A very curious case is reported by Dr. D. A. Zambaco (*Des Affections Nerveuses Syphilitiques*, Paris, 1862, p. 485), in which attacks simulating those of acute meningitis appear to have been produced in a man with a cerebral gummatous tumor by a malarial complication. In such a case the diagnosis of a malarial paroxysm could only be made by the presence of the cold stage, the transient nature of the attack, its going off with a sweat, its periodical recurrence, and the therapeutic effect on it of quinine.

(To be continued.)

—Every one, rich and poor, takes a dip once a day in a caldron of hot water in Japan. The rich bathe before dinner and at night. The whole household dip in the same water. Precedence is given to visitors, then the elders, followed by the young people according to age, and then the servants. On getting out of the caldron each bathers gargles mouth and throat with cold aromatized water. They then fan each other until they are all dry.

EDITORIAL DEPARTMENT.

PERISCOPE.

Symptoms, Diagnosis, Prognosis, and Treatment of Typhlitis and Perityphlitis.

We extract the following from a paper by Dr. Leonard Wheeler in the *Boston Med. and Surg. Jour.*, May 1, 1884:

Symptoms.—An attack of typhlitis is more common in young males. It is usually abrupt, though often preceded by an irregularity of the bowels. At the time of the attack the bowels are usually constipated. Pain and tenderness are complained of in the right inguinal region, there is slight fever and probably vomiting, and the attack may pass off with no greater trouble than this. Such cases are considered common, and are often repeated in the same individual. I have never come across one, however, or if I have, have not recognized it. The attack may be something more severe than this, a tumor be demonstrable, the right leg drawn up, and the decubitus on the right side in order to diminish pressure on the diseased part. The great majority of such cases even recover without the formation of abscess or development of peritonitis, after a duration of from three or four to ten or twelve days, though an induration may remain for months.

Perityphlitis by no means necessarily implies abscess. The symptoms of the most formidable cases are similar to the above, except in degree, until perforation occurs or an abscess forms. A perforation into the peritoneal cavity makes itself very promptly known by the symptoms of acute general peritonitis. A perforation into the post-cæcal cellular tissue is not so manifest, nor is it easy to know when suppuration begins.

Diagnosis.—The number of diseases with which typhlitis and perityphlitis may be confused is large, but in most cases it only seems necessary to have the disease in mind in order to discover it. Mr. Maunder, of London, was called to tap an ovarian cyst, and found a cæcal abscess. Dr. For-dyce Barker narrates two cases, both seen by eminent counsel. The first patient was the wife of a physician, who proved to have a pelvic hæmatocele, although the diagnosis had been perforation of the appendix. The second was daughter of a physician, who proved to have a perforation of the appendix when the diagnosis had been pelvic hæmatocele.

Prognosis.—The prognosis in typhlitis in which no perforation occurs is good. The patients almost invariably recover. When there is a perityphlitis not suppurating, the danger is from recurrences, in which suppuration may take place. Dr. Wm. Pepper has a paper in the *Transactions of the Pennsylvania Medical Society* for 1882, in which he lays particular stress upon this liability to recurrence, and gives one case of twelve relapses. If the disease goes on to perforation, then the result depends in great measure upon the course taken by the pus and the surgical means employed. A perforation through any part covered by peritoneum, including thus nearly all perforations of the appendix, is a desperately

fatal accident. It is possible that adhesions precede the perforation, so that an opening is made directly or through the medium of an intraperitoneal abscess into one of the hollow viscera or through the abdominal wall. If a perityphlitic abscess forms, the most favorable course for the pus is through the cæcum or rectum. Perforation through the abdominal wall is not so favorable. Of twenty-eight cases collected by Dr. Bull, of New York, eleven were fatal.

Treatment.—In non-perforative cases, if there is much pain and tenderness, opium is proper until there is less, then small doses of saline laxative guarded by a small opiate, for it is desirable to relieve the cæcum of contents, both for the sake of diagnosis (to exclude impaction) and to relieve the patient of pain caused by the distended gut. At the same time externally a poultice, ice, or counter-irritation, may be used. Calomel is used by English practitioners generally, and is now and then mentioned by Americans. If an abscess is formed, it is to be evacuated immediately, and if there is a reasonable belief that pus is present, although no fluctuation is found, the surgeon is justified in or is required to test the belief by aspiration or incision. Upon the point of the diagnosis of pus, Dr. Sands writes: "Rigor, sweating, high temperature, acceleration of pulse, abdominal pain and tympanitis, and an increasing extent combined with diminishing firmness of the abdominal tumor, are the chief signs which indicate the formation of pus. But none of these signs is invariably present, and it would be a difficult matter to say which one of them is the most important. But although in the early stages of the disease it may be impossible to discriminate between the cases that are going to terminate by resolution, and those that are to end in suppuration, the latter may usually be distinguished toward the close of the second week by the general unfavorable condition of the patient, who seems to be growing worse instead of better; whereas when resolution is about to take place, the later course of the disease is comparatively mild and favorable." The smallest aspirator needle may be freely used to decide the diagnosis. The operation is done by making an incision parallel with Poupart's ligament through the successive layers of the abdominal wall until the fascia transversalis is reached; the pus is then sought by the needle if fluctuation is not present, and the abscess then opened sufficiently to allow the entrance of a finger to explore the cavity for foreign bodies. Fæcal odor and the presence of bubbles of gas in the abscess do not prove the existence of a perforation of the intestine, though making it very probable. It is well to be aware that a perityphlitic abscess may be quite behind the colon, and extending far upward toward the liver. In such case it would have to be approached from the side. Dr. Noyes, of Providence, has tabulated one hundred cases of this operation. The mortality was fifteen per cent. In Dr. Bull's sixty-seven cases of abscess tabulated in 1872, before the operation came much into use, the mortality was forty-seven per cent.

In cases of perforation into the peritoneal cavity, it has been proposed to make an abdominal section, clean out the cavity, and stitch the opening to the abdominal wound. But the difficulty of diagnosis is too great to allow of spending much hope upon this idea.

On Certain Forms of Intestinal Obstruction that may Follow after Hernia.

A paper on this subject was read by Mr. F. Treves, before the Harveian Society of London, March 20, 1884.

Although after complete reduction of a strangulated hernia, and after recovery from the operation, as a rule, no further intestinal troubles may be expected, apart from such as depend upon fresh accidents to the rupture, certain forms of intestinal obstruction might follow after such reduction.

1. Stricture of the intestine due to cicatrization after ulceration or sloughing of the mucous membrane, or to a form of contracting peritonitis. From the collected cases it would appear that neither the seat of the hernia, nor the duration of the strangulation, nor the nature of the operation, have certain or definite concerns in the production of these strictures.

2. Obstruction due to adhesions. The herniated loop may become adherent to the parietal peritoneum, and cause occlusion by "kinking," or the adhesions may lead to "bands" that may be the means of producing obstruction; omental bands are also common after certain herniæ.

3. Obstruction by the formation in the bowel of a rigid loop. Several examples of this form of obstruction were given, together with examples of a fistula bimuscosa consequent upon injuries received by the strangulated bowel.

Mr. Gant took a different view from the author of the paper, with regard to the origin of stricture of the intestine and looped constriction, as forms of intestinal obstruction resulting from hernia. They were not subsequent conditions, but commenced from the time of operation, owing to the indentation often left upon the bowel at the seat of stricture, when the strangulated portions had been inadvertently returned into the abdomen in that condition. Hence the great importance of the rule he always observed, that of gently drawing down the gut, and of effacing the indentation by gentle manipulation before returning the part into the abdomen. The same might occur after the reduction of enterocoele without operation, and it might be advisable to resort to operation to discover and release any such constriction, even when reduction could be effected by taxis, provided that the duration of the strangulation rendered it probable that plastic constriction might have supervened.

Mr. Cowell criticised the statement that the duration of the hernia had no definite influence upon the liability to subsequent obstructions. Some of the forms of obstruction, and especially those produced by bands of adhesion, were much more likely to be found in old herniæ. In many patients several different portions of intestine in succession found their way into the hernial sac, and were liable to be pressed on, each of them in turn becoming the seat of some inflammatory change and exudation.

Hour-glass Contraction of the Uterus.

Dr. J. J. Gorham thus writes in the *Brit. Med. Jour.*, March 22, 1884:

I believe a useful chapter could be added to modern works of midwifery on the use and abuse of the binder, enumerating under the latter category the liability of inducing hour-glass contraction by its improper application. The contributions in the *Journals* of February 16 and March 8 (pp. 312, 456), by Messrs. James and Chappell, serve to confirm a view I have always held as to one of the causes, perhaps the most frequent cause, of hour-glass contraction. My experience differs from Mr. Chappell's as to the time when the binder produces its dangerous action. I believe this danger is almost always caused by the irregular pressure of an improperly-applied binder on the temporarily inert uterus after the birth of the child, and before the separation of the placenta, and that its production is often purely mechanical (i. e., by constriction), instead of being induced by irregular muscular action, as is usually supposed. This theory would scarcely meet Mr. James's case, unless the binder in that instance had been readjusted on the completion of the second stage. The following brief record of a case which I attended comparatively recently will, I hope, clearly illustrate my meaning:

Mrs. K., who had previously nine children, all with one exception natural labors, sent for me on her tenth confinement. On my arrival at the house, the os and passages were fully dilated, the head presenting at the brim; the membranes had broken an hour before my arrival. After waiting a short time, and seeing that the head had not advanced, I put on the long forceps and delivered, whereupon a second child was found in the uterus. This was turned and delivered, and, in the absence of anything better at hand, I extemporized a binder out of a small shawl, and, after having given a full dose of ergot, I waited for the completion of the third stage. After half an hour, the insertion of the cord into the placenta not being reached with the finger, I introduced my right hand with some difficulty through the os, and, after examination, I found complete hour-glass contraction, with the greater portion of the placenta imprisoned in the upper cavity. I had some difficulty in passing my index and middle fingers through the constriction, so tightly did it embrace the placenta; and, on manipulating with the left hand outside the abdomen, the cause of the mischief became at once apparent. The binder, instead of forming a firm support for the fundus of the uterus, had collapsed, and formed a constricting cord round the abdomen near the umbilicus. On removal of the binder, all difficulty shortly ceased, the placenta was removed *en masse*, and the woman made a rapid recovery.

—Two cases of chronic mercurial poisoning are mentioned by Neukirch (*Edinburgh Medical Journal*, March, 1884), interesting enough owing to the cause, viz., the impregnation of the air of patients' sleeping apartments with mercurial vapor from imperfectly amalgamed looking-glasses. He supposes that such cases, in obscure forms, may be frequent enough, as one of his had suffered for four years before the cause was discovered.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, - - -	2.50
Reporter and Compendium. - - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - - -	6.25
Reporter, Comp. and Pocket Record, - - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

AN OBSTETRIC CASE

(Price, \$15.00),

OR

AN ELECTRIC BATTERY

(Price, \$25.00),

AS PREMIUMS.

Any subscriber to the REPORTER who will send us before the 1st of July the names of *three* new subscribers with their yearly subscriptions (\$15) or *five* new subscribers with \$25.00, will receive, for the three, an Obstetric Case complete, and for the five, an Electric Medical Battery complete. They are new, of the best make, and of guaranteed excellence. The new subscribers will receive the REPORTER *free* from the date of the remittance until July 1st next.

PHILADELPHIA, PA.

THE MINERAL WATERS OF CRESSON.

Dr. Carl Seiler, at the recent meeting of the American Medical Association, held at Washington, D. C., read a very interesting paper on the medicinal value of the mineral springs at Cresson, Pennsylvania. During his remarks he said that there are at Cresson three springs:

1. One a very strong iron spring, which, according to the analysis made by the Pennsylvania State Survey, ranks with the best so-called steel springs of Europe.

2. A ferruginous alum spring and a weak magnesia spring. These waters he used on a number of patients suffering from chronic catarrhal inflammation of the upper air-passages in the form of sprays applied locally to the diseased mucous membrane and the iron and magnesia waters internally, with proper regulation of the diet of the patients.

Thus he found that the ferric alum water had a decided tonic and stimulating effect in those cases of atrophic nasal catarrh which were complicated with pharyngitis sicca and chronic laryngitis, and that the beneficial effect of the local application was very soon apparent to the patient. In these cases selected for trial, no other treatment was used so that there should be no error possible in determining the therapeutic value of the application.

The iron water he found to have no very decided effect upon these cases, but to be of great value in cases of follicular pharyngitis and in the milder forms of hypertrophic nasal catarrh, as well as in cases of ordinary simple chronic laryngitis and bronchitis.

The magnesia water locally applied gave no results whatever, and he very soon desisted in using it for topical applications, but found it a valuable adjuvant in the treatment of patients suffering from lythæmic inflammations of the mucous membrane of the upper air passages. In these cases the patient was directed to drink the water freely, and its slightly diuretic effect soon became apparent.

The iron spring also is somewhat diuretic in its

action, but is chiefly valuable as a tonic, particularly in cases with feeble digestion.

Artificially prepared solutions of iron and ferric alum, which he used in a number of cases similar to those which were treated with the natural waters, did not have the same effect; and this fact strengthened his belief that it seems impossible to manufacture an artificial mineral water in the laboratory of the chemist, which is equal in its value to that produced in nature's laboratory.

Almost all the European authors on diseases of the lungs and upper air passages lay great stress upon the value of the natural mineral waters in the treatment of these disorders, and advise their patients to go to one or the other of the many watering places on the continent. In America, on the other hand, although we have mineral springs of equal, and even greater therapeutic value than are found in Europe, yet the medical profession at large does not seem to recognize the fact, and they are little patronized, with the exception of a few, where, however, the waters form the least attraction.

This may, perhaps, find an explanation in the fact that in this country, everything being free, the patients at these watering-places are left to their own choice as to the quality and quantity of the water they are to drink, and are not in the least restricted as to their diet, which, as a rule, is either altogether insufficient in quality or sumptuous beyond reason. In Europe, however, the effects of the different mineral springs are well known to every educated physician, and when he sends a case to a watering place, it is not a random patient which, perhaps, he is anxious to get rid of for a time, but he selects that mineral spring which is most suitable for the disease from which the patient is suffering. At the springs there is also a physician appointed permanently by the company or State owning the ground, who has made a study of the therapeutic action of the mineral waters, and who directs every patient as to which of the waters, if there be more than one spring at the place, he is to drink or use, how much, and in what form, whether internally, by local application, or in the form of baths, and

finally, gives careful directions as to diet and exercise compatible with the use of the mineral springs.

We cannot expect that change of air and the indiscriminate use of a mineral spring alone should produce those marvelous effects which we so often hear about as having been produced by this or that German spring, unless we combine hygienic measures with our therapeutic agents.

The mineral springs of Cresson, viewed from this standpoint, will, he has no doubt, soon be recognized as extremely valuable in the treatment of all catarrhal affections of the mucous membranes, which is enhanced by their situation and surroundings. They are located near the summit of the Alleghanies, at an elevation of 2300 feet above the level of the sea, and within a few miles of the celebrated Horseshoe Curve of the Pennsylvania Railroad, thus affording a moderately high altitude with a moderately dry climate, one that is eminently suited for catarrhal diseases. The hotel accommodations are excellent, and the place is free from many of the objectionable features of other more fashionable watering-places, such as drinking-saloons, gambling-hells, race-courses and the like, which aside from the bad moral effect, must necessarily materially interfere with the needful rest, free from excitement, so necessary in the treatment of most chronic diseases.

THE PROPRIETY OF ARTIFICIAL FECUNDATION.

The French journals have lately been discussing the propriety of the operation for artificial fecundation, apropos of a case which occurred at Bordeaux last year, and which we mentioned at the time.

One side maintains that the operation might lead to injurious social results; that the physician oversteps the bounds of his art in suggesting it; and that it is in violation of the sanctity of marriage.

The advocates of the procedure argue that it is a perfectly ethical undertaking; that it is no more threatening to social morality or the privacies of marriage than any other treatment for sterility; that it offers a means for removing one

of the most certain causes of unhappiness in married life; and that if properly carried out there is no more violation of proprieties than in making an ordinary examination with a speculum. The procedure of Prof. Pajot is recommended. He appoints an hour for coitus to take place, calls about an hour later, introduces a syringe in which he takes up a little of the seminal fluid, and throws it well into the uterine cavity. The result is frequently successful.

NOTES AND COMMENTS.

Obstinate Hæmaturia.

This trouble is oftentimes so rebellious to treatment that the case which a correspondent of the *Lancet* (April 5, 1884,) records is well worthy of note:

About two years ago J. S—, sixteen years of age, received at school a blow on the right lumbar region, which caused pain and swelling for a few weeks, when the urine became loaded with blood. He was treated by neighboring surgeons with various remedies, without any perceptible decrease of the bleeding. As the poor boy became terribly blanched and weakened, his father brought him to the Royal Infirmary at Liverpool, where he stayed for about two months, which appeared to have no effect, as the bleeding, which always took place when resting for a while in bed, was as bad as ever, but the quantities lost were not so large. He was discharged, and told to continue the infusion of ergot and keep quiet. The bleeding continuing and death being imminent, he again sought admission to the Royal Infirmary, and was admitted. He remained a month; rest and quietude appeared to improve him a little, as all medicines were discontinued. The physicians diagnosed calculus, and suggested an operation, to which the boy and his parents objected. Upon his return home I saw him, and, having heard nothing of his previous history beyond the fact of his ailing so long, ordered him to bed and prescribed sulphuric acid and sulphate of iron in quassia infusion, the specific gravity of the urine then being 1032, and the color a dark blackish-brown, with a layer of blood after standing a few hours. Heat and nitric acid converted the recently-made urine into a solid mass of a black bloody color, which state of things continued for a month. I now prescribed ergot and muriated iron, with exactly the same result. I began gal-

lic acid in ten-grain doses, and continued for a couple of weeks. Finding all remedies equally useless, I asked the advice of Dr. Lionel Beale, which he, in the most handsome manner, gave, and I publicly thank him for so doing. He said: "Give gallic acid in any dose the stomach will bear, and continue as you have been doing." I began with thirty grains every four hours, and afterwards every three hours, with most decided benefit, the stomach retaining those large doses. One month after this latter treatment, the urine presented the following characters: Specific gravity, 1010; color, pale straw; no blood or albumen with heat and nitric acid. The boy has gained twenty-six pounds, and is going about as before the accident, regaining health and color daily. He has ceased taking medicine for the last ten days, without any bad effects. What I wish to point out is the difference of the doses, and the impression which the large doses of gallic acid seemed to have made on the system.

Causation of Sex.

A careful statistical study of the causation of sex has been completed by Dr. Schumann. His studies are based on the census of Norway and Alsace, the only ones in Europe which offered the necessary facts. His most important deduction is that both relatively and absolutely, the determination of sex is related to the vigor of the parent. Each sex has a tendency to reproduce itself, and the sexually stronger of the pair exerts the most influence. Males above 35 or below 25, beget more males than females; so also males living in cities are more apt to have female children than those in the country; facts which our author attributes to the greater debility of the fathers.

We do not pretend to dispute these facts, but the interpretation offered is not the only, perhaps not the most plausible one that could be made.

A New Test for Peptones.

In the suit of Dr. Carl L. Jensen against Keasby & Mattison, as a test case against the alleged infringers or imitators of his pepsin products, Dr. Jensen brought to light that the well-known test for bile (Pettenkofer's) is also a test for peptones in general. This may lead to some important suggestions as to the origin of the bile, and whether it is not one of the earliest products of the digestive process. The presence of the bilic acids in peptic ferments would seem to intimate this.

NEWS AND MISCELLANY.

American Surgical Association.

At the fifth annual session, held in Washington, April 30, May 1, 2, and 3, 1884, the following papers were read:

"An Experimental Study of Anæsthesia," by Dr. B. A. Watson, of Jersey City. "Some of the Dangers and Disadvantages of Anæsthetics," by Dr. David W. Cheever, of Boston. "Wounds of the Intestines," by Prof. S. D. Gross. "Ligation of Common Femoral Artery," by Dr. L. McLane Tiffany, of Baltimore. "Traumatic Cephalhydrocele," by Dr. P. S. Conner, of Cincinnati. "Surgical Interference in Cerebral Abscess," by Dr. C. B. Nancrede, of Philadelphia. "Surgery of the Hand, Especially as Applied to Railroad Injuries," by Dr. Joseph W. Thompson, of Paducah, Ky. "Clinical Observations on the Treatment of Some Railroad Injuries of the Extremities," by Dr. James McCann, of Pittsburgh. "Philosophy of Manipulation in the Reduction of Hip and Shoulder Dislocations," by Dr. Moses Gunn, of Chicago. "Tracheotomy in Croup," by Dr. George W. Gay, of Boston. "The Multiple Wedge Principle in the Treatment of Organic Strictures of the Urethra," by Dr. John S. Coleman, of Augusta, Ga. "Trifacial Neuralgia," by Dr. J. Ewing Mears, of Philadelphia. "Trepanning for Insanity," by Dr. William A. Byrd, of Quincy. "Trephining for Epilepsy," by Dr. William T. Briggs. "Extirpation of the Tongue in Cancerous Affections," by Dr. Basil Norris, of Washington. "The Treatment of Indolent Suppurating Bubo by Extirpation," with cases, by T. F. Prewitt, M. D., St. Louis, Mo. "Artificial Respiration in the Sitting Position," by Henry F. Campbell, A. M., M. D., Augusta, Ga. "Clinical Notes," by Donald Maclean, M. D., Detroit, Mich. "Supra-Pubic Lithotomy," by W. S. Tremaine, M. D., U. S. A., Buffalo, N. Y. "Some Points on the Pathology and Surgery of the Prostate," by J. W. S. Gouley, M. D., New York city. "The Localization of Perinephric Inflammation by means of Chemico-Anatomical Study," by John B. Roberts, M. D., Philadelphia, Pa. "Unsettled Questions in Relation to Injuries of the Head," by David Prince, M. D., Jacksonville, Ill. "Anæsthesia, and Plaster of Paris Bandage in the Treatment of Sciatic Neuralgia," by John A. Cominger, M. D., Indianapolis, Ind. "Practical View of Neoplasm," by E. H. Gregory, M. D., St. Louis, Missouri.

The officers for the ensuing year are as follows:

President.—William T. Briggs, Nashville, Tenn.

Vice-Presidents.—J. C. Hutchison, Brooklyn, N. Y., and E. H. Gregory, St. Louis.

Secretary.—J. R. Weist, Richmond, Va.

Treasurer.—John H. Brinton, Philadelphia.

Recorder.—J. Ewing Mears, Philadelphia.

Council.—Henry F. Campbell, Augusta, Ga.; Hunter McGuire, Richmond, Va.; P. S. Connor, Cincinnati, and J. S. Billings, Washington, D. C. Treasurer John H. Packard, Philadelphia, declined a renomination, owing to a pressure of business.

Washington was selected as the place of meeting, April, 1885.

American Medical Association.

At the thirty fifth annual meeting, held in Washington, May 6, 7, 8, and 9, the following papers were read:

"Address in the Section of Practice of Medicine," by Dr. John V. Shoemaker, of Philadelphia. "Notes of 231 Cases of the Operation for Laceration of the Cervix Uteri without a Single Death," by Dr. T. A. Reamy, of Cincinnati. "Address on State Medicine," by Dr. Deering J. Roberts. "Usefulness of Special Knowledge and Desirability of Using Well defined Special Medical Truths by General Practitioners," by Dr. J. J. Chisholm. "Infectious and Contagious Diseases of Children," by Dr. William Lee, of Baltimore. "Address in the Section of Oral and Dental Surgery," by Dr. T. W. Brophy, of Illinois. "Simulation of Pathognomonic Signs and Symptoms," by Dr. Edward G. Janeway, of New York. "The Clinical Study of the Heart Sounds," by Dr. Austin Flint, sr., of New York. "Dermatitis Herpetiformis," by Dr. Louis A. Duhring, of Philadelphia. "The Etiology of Pericarditis," by Dr. James T. Whittaker, of Cincinnati. "The Production of Poisons by Micro-organisms," by Dr. Black, of Illinois. "The New Official Chlorate," by Dr. Traill Green, of Easton, Pa. "A Periodically Painful Affection, Believed to be Located in the Liver, its Capsule, or Both, or Possibly a True Irritation of the Capsule of Glisson," by Dr. R. Harvey Reed, of Mansfield, Ohio. "Epilepsy," by Dr. William Pepper, of Philadelphia. "The Diagnosis of Tumors of the Anterior Mediastinum," by Dr. Jas. C. Wilson, of Philadelphia. "The Pathology of Myocarditis," by Dr. William H. Welch, of New York. "Irregular Apoplectic Attacks from Other Causes than Hemorrhage or Embolism," by Dr. Caspar Griswold, of New York. "Occult Causes of Disease," by Dr. W. L. Schenck, of Kansas. "The Dietetic Treatment of Diabetes Mellitus," by Dr. A. Flint, jr., of New York. "Phthisis, its Successful Treatment," by Dr. J. P. Miller, of Buckhannon, W. Va. "Tuberculosis," by Dr. Henry F. Formad, of Philadelphia. "Retardation of the Pulse in Mitral Insufficiency," by Dr. A. T. Keyt, of Ohio. "Etiology of Enteric Fever," by S. K. Crawford, M. D., Illinois. "New Theory and Instrument of Diagnosis," by Dr. L. G. Ayres, of Pa. "The Advantages of Massage in Rheumatic Gout," by Dr. Douglass Graham, of Massachusetts. "The Specific Treatment of Diphtheria and Croup," by Dr. George A. Linn, of Monongahela, Pa. "Muscular Hypertrophy of the Stomach," by Dr. Alexander Marcy, Jr., of Riverton, N. J. "Treatment of Typhoid Fever," by Dr. S. K. Jackson, of Norfolk, Va. "Review of the Germ Theory of Disease," by Dr. Henry O. Marcy, of Boston. "Treatment of Compound Fractures," by Dr. Frederick S. Dennis, of New York. "On Railroad Injuries of the Extremities of the Human Body, with Observations on the Site of Amputation and Subsequent Treatment of the Stump," by Dr. T. R. Varick, of New Jersey. "Calculus Fractured Spontaneously in the Bladder," by Dr. J. W. S. Gouley, of New York. "Amputation at the Hip-joint," by Dr. C. A. Wheaton, of Minnesota. "An Earthy Calculus in the Substance of the Liver," by Dr. William A. Byrd, of Illinois. "Branchial Cysts of the Neck,"

by Dr. W. Senn. "The Treatment of Hydrophobia, Historically and Practically Considered," by Dr. C. W. Dulles, of Philadelphia. "One Hundred Experiments upon Abdominal Cavities of Animals, the Injuries being Caused by Gun-shots," by Dr. C. D. Parks, of Chicago. "Chronic Serious Synovitis of the Knee, with Enormous Communicating Popliteal Bursa Extending to Tendo Achilles," by Dr. T. F. Prewitt, of Missouri. "Treatment of Obstinate Cases of Club-foot," by Dr. E. H. Bradford, of Mass. "Entrance of Air into the Veins a Secondary Cause of Death," by Dr. G. L. Porter, of Conn. "Desperate Surgery among Women," by Dr. R. S. Sutton, of Pittsburgh. "Surgical Operations for Cancer of the Uterus," by Dr. W. H. Byford, of Chicago. "Trachelorraphy, by Dr. Joseph Tabor Johnson, of Washington. "Puerperal Septicæmia," by Dr. Theophilus Parvin, of Philadelphia. "The Relations of Ovulation and Menstruation," by Dr. A. Reeves Jackson, of Illinois. "The Management of Protracted Labor," by Dr. W. H. Taylor, of Ohio. "On the Use of Chloroform in Labor," by Dr. J. Herbert Claiborne, of Virginia. "On the Management and Rectification in Difficult Cases of Occipito-Posterior Presentations," by Dr. I. E. Taylor, of New York. "A Paper written by the late Dr. Samuel D. Gross, entitled, "Causes and Prevention of Laceration of the Female Sexual Organs," by Dr. Busey. "A Thousand Cases of Labor in Private Practice, and the Deductions to be Made from the Same," by Dr. W. M. Findley, of Pennsylvania. "Sudden Death in Labor and Child-bed," by Dr. Wm. T. Lusk, of New York. "Malformation of the Female Sexual Organs," by Dr. Brown, of Baltimore. "The Significance of Bloody Discharges from the Bowels in Children," by Dr. Frank Woodbury, of Philadelphia. "Congenital Encephalocele," by Dr. John H. Duncan, of Kansas City. "Diphtheria Based Upon Analysis of 120 Cases, with a Mortality of 7," by Dr. J. W. Brown, of New York. "Septic Jaundice in Childhood," by Dr. M. P. Hatfield. "The Feeding of School Children," by Dr. Louis Atlee, of Philadelphia. "Enlarged Tonsils, and How They Should be Treated," by Dr. Dudley S. Reynolds, of Kentucky. "Incontinence of Urine in Children," by Dr. Samuel S. Adams, of Washington. "Practical Suggestions on the Treatment of the Malignant Forms of Scarlet Fever," by Dr. Bedford Brown, of Virginia. "Neoplasms of Lachrymal Glands," by Dr. P. D. Keyser, of Philadelphia. "Diagnosis in Ophthalmology," by Dr. Williams. "Sympathetic Neuro-retinitis," by Dr. Risley, of Philadelphia. "Method of Treating Chronic Otitis Media," by Dr. H. H. Hart, of Ohio. "Irregular Astigmatism," by Dr. G. D. Theobald. "Influence of Climate on Treatment of Chronic Catarrh of Middle Ear," by Dr. J. J. Fulton. "Epistaxis," by Dr. W. Rankin, of Allegheny. "Diseases of the Ear in Locomotive Engineers," by Dr. L. Turnbull, of Philadelphia. "Rapid Operation on Ripening Cataract, or Artificial Ripening of Cataract," by Dr. C. S. Beele. "Operation for Removal of Nasopharyngeal Fibromata," by Dr. E. F. Ingals. "Chronic Acid Poisoning of Nares and Adjacent Cavities," by Dr. Mackenzie, of Baltimore. "Sarcoma of Pharynx and Soft Palate," by Dr. Bosworth. "Physical Causes of Asthma,"

by Dr. Cutter, of New York. "Caries of Teeth, and its Relations to the Germ Theory of Disease," by Dr. George V. Black, of Illinois. "Importance of, and Treatment for, assuring Healthy Dentine over Endangered Pulp," by Dr. Jacob L. Williams, of Massachusetts. "Sponge-grafting," by Dr. Edward C. Briggs. "The Removal of Stains from the Teeth Caused by Administration of Medicinal Agents, and the Bleaching of Pulpless Teeth," by Dr. S. W. Harlan, of Illinois. "Overdraft of Nervous or Vital Power as Affecting General Special Health," by Dr. Jacob L. Williams. "A Case of Vicarious Hemorrhage from the Gums associated with Pyorrhœa Alveolaris, the Result of Amenorrhœa," by Dr. A. W. Allport, of Ill.

If any of our readers are interested in any of these papers, they can be procured by addressing the authors.

Officers for ensuing year:

President—Henry F. Campbell, Georgia.

Vice-Presidents—J. S. Lynch, Maryland; S. D. Mercer, Nebraska; J. W. Parsons, New Hampshire; H. C. Ghent, Texas.

Treasurer—R. J. Dnnglison, Pennsylvania.

Librarian—C. H. Kleinschmidt, District of Columbia.

Chairman of Committee of Arrangements—S. D. Logan, New Orleans.

Assistant Secretary—W. H. Watkins, New Orleans.

Place of meeting, New Orleans, last Tuesday in April, 1885.

Pennsylvania State Medical Society.

The thirty-fifth annual session of this Society was commenced in Philadelphia, May 14.

At ten o'clock the session was called to order by the President, Henry H. Smith, of Philadelphia. He was supported by Drs. Schultz and Van Valzah, the Vice-Presidents. After a fervent prayer by Rev. Dr. John S. MacIntosh, invoking the blessing of the Almighty on the efforts of the association to alleviate the sufferings of humanity, the Secretary, Dr. W. B. Atkinson, read the register of the members.

Then Dr. John B. Roberts, Chairman of the Committee of Arrangements, delivered the address of welcome. He said:

"To you, Mr. President; to you, ladies and gentlemen, members and delegates of the Medical Society of the State of Pennsylvania; to you, its invited guests, I, on behalf of the Philadelphia County Medical Society, extend a cordial greeting. The Society last met in this city at the time we celebrated the one hundredth anniversary of the Declaration of Independence. I welcome, then, an eight years' absent guest. During these eight years, growth in members, growth in influence, growth in scientific knowledge, has given the Society added fame. This is amply shown in the programme prepared for the present occasion, which is full and varied—too full, indeed, do not the members rigidly observe the rule limiting the length of papers. That this wholesome law may not be disregarded, it looks upon us from the first page of the printed card of exercises; of this, an underscored copy has long since been sent to every speaker. Thus, early opportunity for condensing press and pruning-knife was given all.

The varied scientific dishes have been grouped to suit the palate of the surgeon, of the physician, of the specialist; to the end that no intellectual indigestion may follow undue intermingling.

"That your visit may be profitable and undisturbed by clouds of discontent, that your next absence may be brief, and your return joyous, is our most earnest wish. But, Mr. President, he is welcomed best whom words stay not upon the threshold. I bid you, then, 'Come in;' our hearts, our homes are yours."

Governor Pattison was introduced by President Smith, and he was greeted with loud applause. He said:

"The Commonwealth of Pennsylvania derives exceptional honor from the character and reputation of her medical profession. Its ranks are lustrous with great names, and its history with great achievements that have given her fame throughout the world. The State has undoubted prominence by reason of its great scientific progress and the achievement of her physicians and surgeons. And it should be remembered that it was here that the first system of medical study was formulated in this country, upon which was founded our venerable University. Philadelphia might be termed the Edessa of medical instruction, as the place of beginning and as the chief centre of the science to-day. Our colleges and schools and their professors have given us a great reputation throughout the world."

He made a graceful allusion to the death of Dr. S. D. Gross, and said that while we met now under a great shadow and sorrow, yet we have his fame and teachings left—he who had the honors of Oxford, Cambridge, and Edinburgh. The Governor congratulated the association on the steady progress made in the science of medicine, and bid the members God-speed in the great work of healing, and hoped they would continue to uphold the high standard of the profession. His remarks were greeted with general applause.

THE OFFICIAL PROGRAMME

of the meeting was read, and on motion of Dr. Atkinson the privileges of the floor were tendered to Dr. Rockwell, representative of the Ohio Medical Association, and he was invited to a seat by the President. Dr. J. C. Berry, of Japan, and other visitors, were welcomed to the convention.

Dr. Hudson, of Mifflin county, read an extended report of the proceedings of the American Medical Association at Washington recently. Reports of other State societies were then read, but possessed no points of special interest.

Dr. H. C. Genth, President of the Texas Medical Society, was invited to a place on the platform.

Reports of the Corresponding Secretary, of the Library Committee, Committee of Publication, County Medical Examiners, various County Medical Societies, Anti-Vivisection Society, and the Committee on the State Board of Health, were read.

ADMITTING LADY DELEGATES.

The secretary read the names of several lady physicians, who applied for admission; but, as they were not members of the County Medical Society, he did not let them in. Dr. J. L. Stew-

art, of Erie, objected to the admission of the ladies, but President Smith said they were physicians, and as such were entitled to sit with their brethren. He thought they could enter, take seats, and be heard, but he had no power to give them the right to vote.

This was followed by the presentation of a list of names of persons who were invited to take part in the proceedings, and become "members by invitation." All were ladies except Drs. Da Costa and Ruschenberger, and were as follows: Dr. Clara Marshall, Dr. Anna Broomall, Dr. Frances Emily White, Dr. Hannah T. Croasdale, Dr. Rachel L. Bodley, Dr. Ida E. Richardson, Dr. Emeline Dubois, Dr. Emma V. Boone.

Then followed the same courtesy to the members of the Philadelphia County Medical Society not delegates. The significant thing about this action is that the Philadelphia County Medical Society refused to admit these ladies to membership in their society, thus taking an opposite position to the medical societies of other counties, where ladies are admitted.

The question of publishing papers before they were prepared for publication by the proper committee was discussed with some spirit. It was stated that certain "advertising physicians" got a column or two published, while the papers prepared by other and more distinguished physicians, on more important topics, are dismissed with a line or two. Dr. Allis declared that this conduct was unprofessional, and ought to be checked.

The matter was finally referred to a special committee of five, which the President said he would appoint later.

STATE BOARD OF HEALTH.

Dr. Benjamin Lee reported that, as the Legislature was not in session, his committee could do nothing in regard to securing a State Health Bureau. The committee urged the necessity of agitating the subject generally, in order that this great boon and means of protection may be secured.

VIVISECTION.

Dr. S. Weir Mitchell read the report on the subject, and, as he had a bad cold, he asked that the delegates would come up front. There was a rush at once of ladies and gentlemen doctors. He recited the history of vivisection and the opposition to it in England. A large number of physicians thought no harm was done by experimenting on animals, and to stop it would check physiological research. The restrictive law passed by Parliament was very unpopular, and was doing much mischief there. It had checked the knowledge of snake poisons and their effects. He had sent to doctors in India for snake poisons to test here, but these were refused because of the law. Fortunately the proposition to abolish vivisection was now unpopular, and probably cannot be passed.

Dr. Mitchell alluded to the reported cruelties of vivisectionists on animals, and said they were ridiculous. There were probably a dozen experimentalists, and they did no great mischief to domestic pets in the attempt to advance science.

In New York the legislature had failed to pass

a restrictive law. It had been charged, here in Pennsylvania, that the work of vivisection was greatly overdone. We know that we have but a few medical schools, and it is only in them that the work is performed. A few over-kindly lawyers and ladies think that we should be restrained. Twenty-four hundred physicians in London, from all Christendom, have solemnly approved vivisection; and while they denounce anything like cruelty to animals, they think that vivisection may be practiced without shock to sensitive feelings.

The committee offered the same preamble and resolutions adopted recently by the American Medical Association at Washington, by a vote of 1,100 to 1, and that a lady whose name could not be ascertained. The chief resolution was opposed to restrictive action because experiments on animals are promotive of science, and so nearly harmless as to be unworthy of opposition. The report was adopted, and the committee was continued.

Reports of the Committees on Insanity and Lunacy, on Medicine and Surgery, the Diseases of Women and Children, Ophthalmology, Otology, Nervous Diseases, etc., were called, but only two were ready at present. A recess was taken for dinner.

On re-assembling at two o'clock the Secretary made several announcements as to entertainments.

"THE PRESENT OUTCOME OF SANITARY AGITATION IN LARGE CITIES OF THE UNITED STATES."

This was the title of the address on hygiene and state medicine, by Dr. Benjamin Lee. He said:

With all the inestimable blessings which flow from a republican form of government, blessings of which we, as a people, are too thoroughly convinced to have our faith in them easily shaken, he is no true patriot who shuts his eyes to the fact that there are also certain disadvantages not easily separable from it; certainly not as it exists among us at the present day. Under a monarchy, the chief executive usually calls to his aid in solving problems which affect the ordinary conditions of life, trade, and manufacture, the highest scientific ability which the country affords. Experience has demonstrated, in our own case at least, that under a republican form of government, on the contrary, pure science is not held in high esteem by the governing bodies. They are unwilling to look beyond practical advantages, and those mainly as embodied in dollars and cents, or their equivalents. They are quite willing to use the telegraph and the telephone. They would have turned away with an impatient shrug of the shoulders from a Franklin amusing himself with his kite, or a Galvani with his jumping frog's legs: and as for voting the public money for carrying on such child's play, not they! Such being the case, what remedy shall enlightened citizens who wish well to their country employ, to check the evil and prevent the Great Republic from falling behind all other civilized countries in the arts of life? To how great an extent we had fallen behind in many of them, the Centennial Exhibition was a wonderful witness and revealer. Now, as the brave and

sententious Captain Cuttle was wont to remark, "The bearin' o' these observations in in the application of 'em." In no department of governmental supervision do the United States of America make so poor a showing, as compared with the "effete monarchies of Europe," as in that of the care of the public health.

Within limited areas and in small communities, much may be accomplished by private effort, and this fact hygienists have not been slow to appreciate. But ago-between was needed to interpret their teachings to the masses, and impress upon them their importance. This agency has developed itself in voluntary sanitary associations. Modeled upon one started in the ancient and filthy city of Edinburgh, the first in this country was started in Newport, Rhode Island. This was followed by a second in Lynn, Mass., and a third in Orange, N. J., then in rapid succession by others in other cities and villages, until now there are not less than a hundred and seventy in active and beneficent operation throughout the country, that of Brooklyn, L. I., being the largest and most important. The objects of these associations are, first, self-protective, by indicating, as far as may be, sanitary defects and dangers in the homes of their members, and of neighbors of their members, suggesting remedies for such defects, and urging their application; and secondly, educational, (a) in the most practical way by actual demonstration of the necessity for, and the benefits of, sanitary science, as above stated, and (b) by the dissemination of popular tracts expressed in simple, intelligible, and forcible language, giving both general information and practical hints in detail as to the sanitation of the dwelling. Such an association is in reality a mutual insurance company for the preservation of private and public health. It is not intended as a substitute for municipal inspection, and will not conflict with the public health authorities, where such exist, but will supplement their action.

But the citizen who has had the sanitary defects of his dwelling pointed out to him—defects which hourly threaten the lives and health of his loved ones—finds himself, like Christian in the Slough of Despond, with an awakened sanitary conscience, an enlightened perception of his danger, but with no hand stretched out to help him.

And just here is to-day the encouraging feature to the sanitarian. There is no better test of the success of any movement of reform, than that capitalists are willing to embark their means in carrying it on. With a view to filling the hiatus which I have indicated as existing in our large cities, between the appreciation of the evil and the application of the remedy, stock companies have been formed. These companies engage, with more or less modification of course, determined by the special character of each, to make inspections, both special and periodical, of dwellings and buildings confided to their care, as far as their sanitary condition is concerned; to indicate defects, if any exist, and to remedy those defects by introducing sanitary appliances of the best material, most approved pattern, and most scientific construction, under the supervision of thoroughly qualified experts; to furnish plans and specifications for the sanitary system of new buildings and of grounds,

and to take complete charge from the outset of the introduction of such systems.

Probably the earliest of these companies in the field was the "Durham House Drainage Company, of New York." Its specialty consists in manufacturing its own materials, of scientific design and correct mechanical construction, but it undertakes only the main drainage system. Its responsibility ceases where that of the plumber begins. The "National Anti-Sewer-Gas Company," organized in this city, but having already a branch in New York under the name of the "Manhattan Anti-Sewer-Gas Company," aims to prevent the introduction of sewer-gas into houses by offering a perfectly constructed water-seal for closets, and by a system of thorough inspection and disinfection of the drainage.

The "Sanitary Protective and Mercury Seal Company," of this city, proposes to take charge of both the construction and the inspection of buildings, so far as their sanitary arrangements are concerned, giving the preference to its own seals and closets, the merit of which consists in the fact that the ingress of foul emanations from sewers, cess-pools, or drains into the dwellings is prevented by the interposition of mercury, through or by which they can by no possibility force their way. This company has connected with it an "advisory council," consisting of a hygienic consultant, a medical consultant, and a sanitary engineer, whose duty it is to pass upon all reports of inspectors, plans of drainage and specifications of construction, and without whose approval no plan can be carried into effect by the employees of the company.

The "Philadelphia Drainage and Construction Company" also offers its patrons the advantages of frequent inspections by competent officers, but especially invites opportunities for designing and executing the systems of drainage of country seats, villages, seaside hotels, and so forth.

I do not say that the evil of which I have been speaking is an unmixed one. Possibly the work of inspection is more carefully done under the auspices of private companies than it would be by government inspectors. Possibly the stimulus of competition may lead private corporations to use better materials, and execute more satisfactory, and plan more scientific work than would be insisted on by routine officials; but the fact remains, that it is a public duty performed by private citizens, in consequence of the failure of our legislative bodies, state and municipal, to arise to an intelligent appreciation of their responsibilities as conservators of the common weal.

Dr. E. A. Wood, of Pittsburgh, then read a paper in which he discussed the question of, and strongly advocated the establishment of a State Board of Health in Pennsylvania.

Dr. Henry Leffmann followed with a paper on

PROPER MEDICAL EDUCATION,

claiming that the present system of medical education is not the result of efforts to meet the needs of the community, but is largely an irregular development. The reforms which medical colleges have adopted, have been mostly unwilling concessions to public sentiment. The seven fold division of branches has nothing to recommend it but antiquity; it is not a convenient nor a scientific division

of the subject. Under the arrangement, some of the departments of the college course are overcrowded; others have not sufficient matter to occupy the time assigned. Departments like hygiene, mental and nervous diseases, and medical jurisprudence, have developed so of late years that they might properly be taught by separate chairs, and not made merely subsidiary to other chairs, or limited to spring or fall lectureships. The extension and success of post-graduate schools indicate the direction in which the improvement of the curriculum should be made.

Higher specialization is the necessity of the time. The success which has been attained by dentistry shows that other departments, such as otology, laryngology, etc., might with advantage be pursued independently. There would be no reasonable objection to establishing the degrees of Doctor of Otology, Ophthalmology, and so on, commensurate with the degree of Doctor of Dental Surgery.

A preliminary training for the student before entering on the study of medicine is so obviously necessary that it need not be argued.

The final work of medical reform will be accomplished when the college is made merely the instructor, the license to practice being given by an official board of examiners after a written public examination.

Dr. Thomas H. Fenton, of Philadelphia, read a paper entitled

"HYGIENE IN THE PUBLIC SCHOOLS,"

in which he said:

Two hundred and twelve thousand children attended the public schools of Philadelphia in 1880. The value of the school plant was \$6,179,750. The location of many buildings was faulty as to light and air. Ventilation especially is defective, no provision being made for the exit of foul air beyond the opening of the windows. Special care has been taken to ascertain the truth of this point by accurate and careful tests, which were described at length by the lecturer. The means for remedying this were referred to, and plans given for securing a free supply of air at proper temperature without drafts. The next defect noted was that of drainage, and the poor arrangement, especially of water closets, was considered.

Next came the important point of desks and seats, and the bad effect of careless arrangement of these upon the spine, the chest, and the eyes, was dwelt on at length. The prevalence of myopia was stated, and the difficulty of managing it without proper arrangements for holding books, etc., before the eyes of the children at proper distances was defined. The plan of allowing the light to fall directly upon the faces of the pupils was condemned, and the lack of proper illumination of blackboards was referred to. The color of walls, ceilings, and the paper of books, was stated to be very important. Many important suggestions as to the better care of the children attending our schools were made, and the paper was full of interest.

Then followed Dr. Alice Bennett's address in mental diseases. The authoress chose for her subject the

RELATION OF HEART DISEASE TO
INSANITY,

and said that it has become the privilege of those appointed to give the annual address in any of the special departments of medicine sometimes to depart from the customary and avowed object of such appointments; so that, to-day, I will ask your leave, in place of a general survey of the year's work, in the whole field of "mental diseases," to give you the results of some clinical studies of heart disease among the insane.

This subject has received but slight attention at the hands of alienists and others, and its literature is extremely meagre.

We read much of changes in the kidneys, liver, lungs, and other viscera, but comparatively little of alterations in the brain, as a result of cardiac disease.

The physiological mode of action of brain and nerve cells being utterly unknown to us, the manner in which such action may be modified can be but a matter of conjecture. But it is not unreasonable to suppose that irregularities of the circulation, such as are common in organic heart disease, may have an influence in modifying the action of an organ so peculiarly open to impressions as the brain, and whose anatomical connections with the heart are direct and intimate.

Writers on diseases of the heart refer but briefly, "some not at all," to this subject.

Fothergill believes heart affections to be rather rare among the insane, while admitting that physical disturbances are often seen in the course of valvular disease in the form of bad dreams, changes in character, etc. He also cites some cases of positive mania in the advanced stages of heart disease.

Flint says that while it is conceivable that congestion, extravasations, etc., may follow heart disease, clinical facts show that serious cerebral disturbances are rarely seen.

The standard works of the day on mental diseases are equally indefinite and unsatisfactory.

Griesinger concludes that the influence of cardiac disease was very much over-estimated by the older writers, and quotes statistics in support of his statement that "heart diseases are rather rare than frequent among the insane."

Bucknill and Tuke cite some cases of temporary insanity in rheumatism with cardiac complications, and refer briefly to an exhaustive paper by Dr. Burman, in West Riding Reports, 1873, without other comments than that the subject "requires further elucidations." Some of Dr. Burman's conclusions given in the paper alluded to, are as follows :

1. Affections of the heart are common among the insane, 50 per cent. of 500 insane patients dying, and 44 per cent. of 680 living patients giving evidence of such disease.
2. That such disease is most frequently found associated with hypochondriacal melancholia, monomania of suspicion, and in such modified forms of general insanity as those in which the patient is morose, sullen, or impulsive.
3. That the suspicion of causal relation is justified by the frequency of coincidence.
- He found the proportion of cardiac complications in the different forms of insanity to be as follows :

Melancholia, 48 per cent.; general paralysis, 32 per cent.; recurrent mania, 27 per cent.; epilepsy, 18 per cent.; dementia, 16 per cent.; chronic mania, 14 per cent.

In the above classification, "chronic mania" evidently must include what he calls "monomania of suspicion," and probably also those characterized as "morose, sullen, or impulsive."

Dr. Savage, of Bethlehem Hospital, in a short paper also alluded to by Bucknill and Tuke, concludes that the prevailing form of insanity associated with "heart disease" is "melancholia." The following is an analysis of 500 cases examined in the "Female Department of the Hospital for the Insane" at Norristown, taken without discrimination :

	No. cases examined.	Normal hearts. . .	Abnormal hearts. .	Percentage of heart disease.	Percentage found by Dr. Burman. . .
Acute mania	18	4	14	22.2	
Chronic "	148	47	101	31.75	14.73
Recurrent "	28	9	19	32.14	27.77
Acute melancholia .	15	2	13	13.3	
Chronic "	29	2	27	8.89	48.21
Dementia	185	22	163	11.89	
Senile dementia . .	11	1	10	9.09	16.26
Paralytic "	6	3	3	50.	
General paralysis. .	3	0	3	0.	32.
Epilepsy.	28	8	20	28.5	18.18
Inbecility and idiocy.	29	3	26	20.	
Total	500	101	399	20.2	

Form of disease—	
Simple irregularity	11
Hypertrophy and dilation	4
Apical systolic murmur	70
With basal systolic	16
Total	101

The whole percentage is seen to be less than that reported by Dr. Burman, and the proportion among melancholia decidedly much smaller. In the two cases of acute melancholia given, the associated heart trouble did not hinder a rapid recovery. Feeble action of the heart was noted among the advanced dementes. Accentuations of the aortic second sound in the three cases of general paralysis also noted, as pointed out by Fothergill. There was also a very general absence of hæmic murmur.

But it is the coincidence of heart disease, with a certain form of chronic mania, to which this paper is specially designed to call attention. (Here follow abstracts of the histories of sixteen cases possessing similar features, and all presenting evidence of mitral disease.) These cases constitute a distinctive class, easily recognized by the merest novice. Some of the general features running through them that you will have noticed, are as follows :

They begin generally in middle life. The invasion is gradual, generally ascribed to no cause, or to one obviously inadequate. The first symptoms are invariably hallucinations of one or more senses, generally of hearing, and subsequent delusions of persecutions. A woman previously supposed to be in good health, begins to hear voices, sometimes through tubes in the walls, sometimes in the ceiling above her. The ringing of bells, noxious smells, the odor of chloroform, may all come apparently to her perceptions, and to her mind they very naturally assume the form of persecutions from enemies known or suspected. There follow naturally upon this suspicion of every one about her, perverted affections—paroxysms of most violent language, and sometimes of violent acts. Some of our most dangerous lunatics may be developed from this class, when the voices take the form of “revelations” or inspirations. Yet many of them are merely troublesome and noisy. They are often removed from home for the simple reason that they are obnoxious and abusive to their neighbors. Among this class we find some of the most quiet inmates of our hospitals; some not obviously insane to casual observation, who have remained in stationary conditions for years; others beginning in the same way show a tendency progressing toward a general misconception of all the facts of their daily life. In four of the cases given above, delusions as to identity were present.

The following 24 cases present salient features characteristic of this class, although not so typical and unmixed as those given above. All have hallucinations of hearing, and all have disease of the heart, generally mitral insufficiency. (Here are given short abstracts of 24 cases, of which the prominent features are hallucinations of hearing with associated delusions.)

Of the 47 cases of chronic mania found to have heart disease, 40 are given above; of the remaining seven, two began as violent acute mania, three are of a recurrent type, consisting of paroxysms with general incoherence and mixed delusions, one is of unknown history, and has delusions relating to wealth. In none are hallucinations known to be present. It is only fair to look at the 101 cases of chronic mania, showing no cardiac disease. The list comprises a great variety of conditions. A number began as violent acute attacks that have never recovered. These show all kinds of delusions, generally changing and transitory; there are some hypochondriacal and hysterical cases; a number are traced to the use of alcohol. Very many have come to us with history unknown.

A careful examination of the whole number shows only three cases which have any resemblance to those given above. One of these is deformed by disease of the spine; she has made homicidal threats in consequence of supposed injuries; one has progressing phthisis, and her insanity was attributed to alcohol; of the third, nothing is known, except that she goes about beating the walls with her shoes, probably under the influence of hallucinations.

It is not my intention to draw any inference from the above cases, which I do not offer as anything more than a rather remarkable series of coincidences. It has only been shown that among

500 patients, a certain distinctive form of mania has been found, almost without exception, associated with valvular disease of the heart, generally mitral. Whether the frequency of the coincidence justifies the suspicion of a causal relation, is for you to determine. Admitting the suspicion, it must be verified, or the reverse, by continued observations.

The Society then adjourned for the day; after which they visited the Pennsylvania Hospital, were received by the President, and entertained at a banquet by the Philadelphia Medical Society.

THURSDAY, MAY 15.

After the routine business, the

ADDRESS IN MEDICINE

was delivered by Dr. W. H. Daly, of Allegheny, in which he discussed scientific investigation and clinical observation, conversatism in medical ethics, the medical profession and its specialties.

Following this, Dr. Charles W. Dulles, of Philadelphia, read a theoretical paper, entitled
DISORDERS MISTAKEN FOR HYDROPHOBIA.

Dr. Van Harlingen then read a paper entitled
**THE PRINCIPLES OF EXTERNAL TREATMENT
IN DISEASES OF THE SKIN.**

The employment of outward applications in the treatment of diseases of the skin has always been largely empirical, a remedy having been chosen in a given case, not with the object of producing a certain desired effect in a known condition of the skin, but because it had been said to be useful in the disease supposed to be present. This “doctrine of specifics” was so prevalent some years ago that but four remedies were commonly employed in skin diseases, namely, mercury, arsenic, sulphur, and oxide of zinc. A disease was either eczema, when arsenic and oxide of zinc ointment was the specific; or it was the itch, when sulphur was to be made use of; or it was syphilis, when mercury was to be employed.

Thanks chiefly to the labors of Dr. Duhring, of Philadelphia, the study of dermatology is no longer the memorizing of an obscure and confused jargon of names. The entire subject is now clear and comprehensible. Time and opportunity are, however, lacking to the student and practitioner to become acquainted with the nomenclature and classification of diseases of the skin. It had therefore occurred to the writer that if the more commonly used external remedies could be classified according to their effects upon the diseased integument, certain principles of treatment might be arrived at which would enable the physician to treat most forms of skin disease according to the appearances presented, without this necessarily involving a knowledge of the nomenclature and classification of dermatology.

The writer then went on to sketch out a scheme by which the various outward applications commonly employed were arranged according to their effect, as protectives, sedatives, astringents, anæsthetics, stimulants, caustics, and mechanical means of treatment, giving under each head the effects of each class of applications so far as

known, together with a list of individual medicaments belonging to the class.

The paper, which was essentially tentative in character, was put forth, said the writer, with the hope of suggesting lines of treatment which might aid the general practitioner in the management of the skin diseases encountered in every-day experience.

Dr. J. H. Musser, of Philadelphia, then read a paper on

A MODIFICATION OF THE SPHYGMOGRAPH,
BEING A CHANGE IN THE BASE OF
THE INSTRUMENT OF POND,

which will appear in full in our next issue.

Dr. J. V. Shoemaker read a paper on

JEQUIRITY (ABRUS PRECATORIUS LINNÉ):
ITS USE IN DISEASES OF THE SKIN.

After giving a full account of the history of this interesting drug and its use at various times, dating back to antiquity, the doctor gives a description of its appearance and parts used, their chemistry, which denotes nothing of the active properties it displays. Its innocent nature, its use as food, along with the above, led the writer to infer that its activity must be looked for either in a new compound formed on addition of water, or the fact that it forms a rich nurture field for atmospheric bacteria. The rapid fungus formation in its infusion induced him to adopt the latter theory, especially, as if these are destroyed by either boiling or antiseptics, the infusion is rendered inert.

Its use in affections of the eyes, first empirically developed by the natives of Brazil, has been closely studied by eminent ophthalmologists, and pronounced by them as of marked value in granular affections of the lids, though so powerful as to deserve great caution in its application. Its result, when so applied, is to produce a specific ophthalmia of a croupous nature, which destroys the granulations and leaves them in a favorable condition to heal. This had led the writer to the deduction that it might be applicable to other morbid processes consisting in exuberant granulations, proliferating cell-growths, and with a tendency to remain in a slowly-degenerating condition, where caustics, escharotics, and superficially-destructive measures seem indicated. While evidently the fungoid development is at the expense of the albuminous components of its infusions, he also deduces that the destruction of cell-growth is caused in a similar manner, and that its own existence is ultimately destroyed by over-production, and the exclusion of atmospheric air by the detritus caused therefrom.

Selecting lupoid conditions, epithelioma, sloughing ulcers, etc., as tests for his theory, he found that a weak infusion, such as is used in ophthalmic practice, was of little avail, and obtained as a more serviceable application an emulsio-infusion from Dr. L. Wolf, the well-known chemist. This, when first applied, produced no pain, but soon set up a specific inflammation, which at times assumed quite alarming proportions, œdematous swelling, with erysipelatous appearance of the surroundings, accompanied by febrile symptoms, though this occurred only in applying it to exten-

sive surfaces, and in highly sensitive and irritable patients. The products of this inflammation cast an immense crust on the surfaces, under the protecting influences of which the constructive process rapidly developed, so that after either forcible detachment, or better spontaneous casting off of the cuirass-like crusts, new and healthy surfaces were apparent, and on repeated applications cures were speedily affected by it.

Dr. Shoemaker demonstrated this by cases from the Philadelphia Hospital for Skin Diseases, all of which showed the greatest improvement and entire cicatrization.

He sums up by stating that he considers jequirity a most powerful agent in certain affections of the skin, and though only to be used under careful supervision and with due caution, it generally gives most excellent results in the class of affections named by him; that it has a still greater field than simply that of ophthalmic practice would readily appear, and that, though his theory and its *modus operandi* may be modified in time, its valuable effect in the cases he named is indisputable, and will be more fully developed as it finds more general application and introduction.

A PLEA FOR CHEMISTRY.

Dr. Traill Green, of Easton, read a most practical and valuable paper with this title. As a result of very many years of observation and experience, he has come to the conclusion that very few physicians know as much about chemistry as they ought to, and even some druggists are very deficient in this knowledge. To illustrate the latter point, he related the experience of a friend of his, who went into a drug store and asked for *chlorate* of sodium. The druggist told him and persisted that this was table salt, not seeming to understand, as Dr. Green said, that there is a difference between a *chlorate* and a *chloride*. He considers it essential that physicians should know more about chemistry, in order that they might avoid prescribing explosive mixtures, as has frequently been done. He warns us that potassic chlorate, glycerine, and tincture ferri chlor., will make an explosive mixture. Potassic chlorate and catechu have been used as a dentifrice; if there is much friction in cleaning the teeth, this mixture will explode. The following formula was ordered by a physician for a woman:

R. Argenti oxidi,	gr. xlviii.
Morph. muriat.,	gr. j.
Ext. gentianæ,	q. s.

Ft. pil. No. xxiv. and silver them.

The woman placed these pills in her bosom for safe keeping, and in a short time an explosion took place. Some nitric acid was put into a presumably clean vial; very soon an explosion, with a loud report, occurred, when it was ascertained that an almost inappreciable quantity of glycerine was in the vial.

In view of the fact that permanganate of potassium has been highly recommended of late in amenorrhœa, Dr. Green advises us not to use an excipient for it that is very readily oxidized, as glycerine; talc or kaolin will be safe. Fluid extract of *uva ursi* and certain samples of spirits of nitre will form an explosive mixture, as will also, sometimes, chromic acid and glycerine.

The ignorance of chemistry he attributes to the fact, that its importance is not sufficiently impressed upon the student and physician, which negligence he greatly deprecates.

Dr. Benjamin Lee followed with a paper on

"MASSAGE—THE LATEST HANDMAID OF MEDICINE,"

in the course of which he said, Benjamin Thompson, Green Mountain boy, American medical student, yankee school-master, colonel of dragoons, knight of Great Britain, chamberlain of the kingdom of Bavaria, count of the holy Roman empire, better known as Count Rumford, philosopher and philanthropist, hero of a history more wonderful than romance, never uttered a profounder thought than when he deduced the conclusion from one of his brilliant experiments on the production of heat without fire, "that anything which any insulated body, or system of bodies, can continue to furnish *without limitation* cannot possibly be a material substance, and that it appeared to him extremely difficult, if not quite impossible, to form any distinct idea of anything capable of being excited and communicated in those experiments except it be Motion." This was the germinal idea from which sprang the whole outgrowth of the modern theory of force, as worked out by such thinkers as Faraday, Grove, Joule, Thompson, Tyndall, and Mayer, as we find it elucidated, for instance, in Tyndall's "Heat as a Mode of Motion," and Grove's "Correlation of the Physical Forces."

Since heat, electricity, and chemical action are inseparably associated with the beginnings of life as well as with its maintenance, it is not too much to regard them as, in the hands of the Creator, the means of its source and origin. And as all of these exhibitions of divine power can be traced back to motion as the ultimate cause or their essential condition, it follows that we must look upon motion as the source and conservator not only of force, but of life.

If now, changing our point of view, we look at the processes of animal life from within, we find as the latest development of physiological research, the animal cell, with the incessant motion of its contents within and through its walls by constant endosmose and exosmose, as the unit and exponent of life, both in its origin and its perpetuation. Irregularity or retardation of motion in the cell contents constitutes disease; cessation of this motion is death. We may, therefore, not inappropriately define a state of health to be one in which the motions of the cell contents are normally carried on. This condition being disturbed, what can be at the same time more natural and more scientific than to introduce motion from external sources to regulate and restore it? This is the function of massage.

When I mention that I have now been familiar with this therapeutic means in the management of chronic functional disease of all kinds, and in the treatment of the sequelæ of local inflammations, for a quarter of a century, I think I shall be absolved from the charge of undue haste or rash enthusiasm, in now for the first time introducing it to the notice of this distinguished body.

By *Massage* I understand the communication of

motion to the tissues of the living human body from an external source, for therapeutic purposes.

The word *massage* comes to us from the Greek through the French, and means simply "*kneading*," the idea to be conveyed being that the operator works the flesh as the baker works his dough. It is better to use the French word than to translate it into English, because the English equivalent is used to describe one of the particular modes of massage, and because it has now a well-established position and definite signification in scientific medical literature all over the world. The attempt to belittle the system by calling it "*rubbing*"—an entirely inadequate designation—can only react on those who employ it, by indicating their partial education and their lack of familiarity with the recent literature of other countries. Avoiding the superfluous verbiage of French writers upon the subject, I adopt the simple nomenclature of Metzger, of Amsterdam, who has done more than any one individual for the scientific elucidation as well as the practical advancement of the art, and name four methods of procedure in massage—*stroking*, *kneading*, *friction*, and *percussion*.

Vibration is a modification of *kneading*. It consists in making the alternate pressure and relief from pressure which constitute the essential features of that form of massage, with extreme rapidity. It may be imperfectly done by the hand, but much more effectively with the aid of a machine, since with this alone can the alternations be made with the requisite frequency.

A knowledge of the physiological effects of massage at once affords the clue to its therapeutic applications. And be it here observed that not the least among its advantages as a remedial agent is the fact that its mode of action is physiological and not pathological—that it removes one diseased process, not by substituting for it another diseased process, as is the case in the operation of internal remedies, but by substituting directly the condition of healthy action. Hence, if performed skillfully and judiciously, there need be no fear of any unpleasant after-results, such as can so often be traced to the administration of drugs, and which may ultimately prove as serious as the original disease. The injury done by the habitual, immoderate use of laxatives by women is an illustration of this fact.

Cervical massage, or massage of the neck, depletes the blood-vessels of the scalp and brain, and may, therefore, be used with great advantage in all congestions of the brain or its membranes, acting powerfully and rapidly, like a copious blood-letting without the pernicious effects of the latter. In the congestive form of sunstroke it is of great value, and also, as pointed out by my friend, Dr. Mills, in the congestive headaches.

Abdominal massage stimulates the circulation of the blood and flow of lymph in the digestive organs, and is extremely serviceable in torpor of the liver, taking the place of the time-honored blue pill; in dyspepsia, especially of the atonic form; in constipation and diarrhœa; in abdominal dropsy, and in congestive and inflammatory conditions of the womb and its appendages. The power which it possesses of removing articular effusions points to its use in all inflammations of the

joints, whether the result of injury or not, whether acute or chronic, except that where the existence of pus is demonstrated, care must be used not to cause its too rapid absorption into the lymphatics. By its employment, the treatment of *sprains*, those opprobria of surgery, which an eminent authority has asserted are responsible for more amputations than all other causes combined, is reduced from a matter of months to one of days.

Anchyllosis of the joints, when not purely osseous, which is of comparatively rare occurrence, and *old rheumatic stiffness* of the joints, can be overcome by this means to a remarkable degree, and often in a surprisingly short space of time, by associating it with simple acto-passive movements. Its ability to relieve pain by producing numbness of the nerves points to it as an agent of great value in the *neuralgias*, especially those in which there is an injected or varicose condition of the vessels of the neurilemma. *Sciatica* has been the form in which it has yielded the most brilliant results, although I have seen an obstinate neuralgia of the brachial plexus, which was rendering life a burden, entirely relieved in five sittings. *Hysteria*, in all its protean manifestations, the so-called fashionable *neurasthenia*, *spinal irritation*, exhaustion of the great sympathetic nerve, and all the nameless types of chronic invalidism, as demonstrated by the brothers Taylor, in New York, and by our distinguished fellow member, Weir Mitchell, in this city, may be successfully treated by it when all other means of cure have been exhausted with only negative, if not pernicious results; and this because it goes to the beginnings of life, of assimilation, and of nutrition, and, commencing in the cell, builds up the system atom by atom, until the individual is literally reconstructed in body, and to a considerable extent even in mind. The same remark applies to its value in aiding convalescence from fevers and other wasting acute affections, and from surgical operations. Its influence in developing muscular tissue indicates it as especially useful in *infantile* and some other forms of paralysis. Even in *locomotor ataxia*, vibrations have been known to produce decided amelioration.

Certain spasmodic affections of the muscles also, such as chorea and writer's cramp, have been treated by it with the happiest results.

In short, not to amplify this already too long catalogue, whenever we desire to profoundly modify the processes of nutrition, to remove effete material from the system, to stimulate assimilation and invigorate digestion, to soothe nervous irritability and relieve nerve pain, to remove morbid deposits from the neighborhood of inflamed joints, and thus restore them to their normal mobility, to equalize the circulation, sending the blood from the hot head, congested spine, engorged liver, or laboring heart, into the cold extremities, we shall, if we are wise, use massage.

If we know how, and can spare the time, we shall do it ourselves. If, as is more than probable, we do not know how, or have not the time to devote to it, we shall employ an experienced masseur or manipulator to do it in our stead, but for the reasons stated, and not because it is in any way beneath our dignity to do it ourselves.

What then shall guide us in our choice of a manipulator? He or she, for both sexes may suc-

ceed admirably as *masseurs* or *masseuses*, must possess—first, vigorous health; secondly, muscular strength; thirdly, a cheerful temperament, a pleasant face, and an acceptable manner; fourthly, a soft and pliant, but strong hand; fifthly, a fair education and a certain amount of refinement; sixthly, a knowledge of the leading facts in anatomy, such as the position and course of the larger arteries, veins, and nerves, and of such facts in physiology as the functions of the various organs, the course of the circulation, and the general processes of nutrition; and seventhly and lastly, an acquaintance with the effects produced by the different forms of manipulation, the order in which these different forms should be employed in order to produce certain general effects, the injury which may be inflicted by employing them improperly or out of their proper order, and a practical dexterity in their application, to be attained only by training under an experienced instructor. Hence it will be understood that we cannot take John from the stable and Biddy from the wash-tub, and in one easy lesson convert either into a safe, reliable, and efficient manipulator. Massage is an art, and as such must be acquired by study and patient practice, under competent guidance. It cannot be picked up at an hour's notice, by any broken-down nurse or disappointed cobbler. As certainly as a trained nurse is superior to an untrained, so certainly, even more certainly, is a trained and well-instructed manipulator better than a self-taught "rubber." In this as in every art, in the words of the great Roman lawyer: *Quamvisque norit artem in hac se exerceat*.

DIPHTHERIA.

Dr. L. B. Kline, of Catawissa, read paper on this subject, in which he said that in consequence of the general and wide-spread prevalence of this malignant and fatal disease, it is one of the most important and practical subjects that can be brought before this Society. While it is one of the oldest epidemic diseases of which we have any knowledge, there is still a great deal of ignorance prevalent in regard to its true etiological and pathological character, and more than a little empiricism in its treatment.

Diphtheria may be defined as an acute, specific, contagious, and infectious disease, of a miasmatic character.

It is both local and constitutional in its character, manifesting itself locally by a fibrinous exudation on the mucous membrane of the throat, this frequently extending to the air-passages, constitutionally by febrile excitement, with its concomitant symptoms and general poisoning of the system.

As to whether the disease is primarily local or constitutional, is still a disputed question. To my mind, the weight of reasoning on the subject is in favor of the former view. The fact that it is usually sudden in its onset, and affects only mucous membranes that are so situated as to be specially exposed to poisonous particles floating in the atmosphere, it seems to me is strong presumptive evidence that the seeds of the disease are deposited locally, and that the general or blood disease is the result of the local affection.

While the peculiar diphtheric deposit may not be visible at the appearance of the first symptoms of the attack, yet as the primary stage manifests itself in the fauces, simply by a hyperæmic and inflammatory condition of the mucous membrane, it is no argument against this hypothesis.

Having located itself on a structure that readily allows the absorption of the infecting material, the general system soon becomes involved, as is indicated by chilliness, succeeded by an increase of temperature and a degree of prostration proportioned to the severity of the attack. That the disease is largely spread by contagion cannot be doubted, yet it is a well-settled fact that sporadic cases recur spontaneously.

Among the causes that favor the development of diphtheria, may be mentioned a want of cleanliness, undue exposure to decaying vegetable and organic matter, sewer-gas, any impure condition of air respired, to whatever cause it may be due.

That malignant diphtheria is highly contagious is now generally admitted; not only is it spread from one individual to another by personal contact, but I am satisfied that it may readily be transmitted by clothing and other objects that have been exposed to the infecting material. The time intervening between exposure to the diphtheritic poison and the occurrence of the disease varies, according to my observation, from two days to two weeks.

In the epidemic that occurred in this town in 1879 and 1880, in the majority of the families in which the disease prevailed, the interval between the attacks of the different members was very short, frequently not more than a single day, while in a small number of instances from one to two weeks would elapse from the occurrence of the first case until a second member of the family was attacked. In one family of seven children, I found a new one down with the disease each successive morning until all were ill.

The history of the following cases shows the danger of those who have recently recovered from the disease, but are still suffering from its effects, coming in contact with healthy children.

A young daughter of Mr. S. was taken sick on March 2. On being called next morning, I examined the fauces, and found it was a well-marked case of diphtheria. Upon inquiry I learned that a sister of Mr. S. was visiting at the house, with three children who had recently recovered from a severe form of the disease, one of the family having died. One of the children, who was still suffering from a sore nose, slept with a daughter of Mr. S. on the Friday night preceding her sickness. There is no doubt in my mind but that the disease was communicated in this way, as there were no other cases in the vicinity, and the disease did not spread to any other family. Three cases occurred in the family of Mr. S.

Physicians should urge a greater degree of caution on the part of families having the disease. Healthy children belonging to the family should not be allowed to attend the public schools, or any place where they are likely to come in contact with other children.

I wish specially in this connection to call attention to the important question of the relation of certain vegetable organisms to diphtheria; the evidence in favor of their presence, as a very impor-

tant factor in an etiological sense, is constantly accumulating, and at present there is a well established connection between the micrococcus species of bacteria and diphtheria. The microscope reveals their presence in a large proportion of cases examined; whether they are present as a result or cause of the diseased process may not be so well settled, but their almost constant existence indicates the importance of the subject to such an extent as to excite the hope that further investigation will develop such new light as will lead to a more rational and successful treatment of the disease. This theory is strongly supported by Oertel, Bartholow, Edward F. Willoughby, and others, all of whom maintain that the presence of bacteria is essential to the diphtheritic process, while the former, who has thoroughly investigated the subject, says, "without micrococci there can be no diphtheria."

In a pathological sense the local lesions have a close connection with the general morbid action. Locally, we find hyperæmia and inflammation of the mucous and subjacent structures of the fauces and pharynx, the diseased action frequently extending to the nasal passages, and sometimes to the larynx and trachea; in very rare cases it may by contiguity of surface invade the stomach, though more frequently the stomach affection is of a secondary character.

In the epidemic already referred to, several instances occurred where patients who were apparently convalescent took suddenly with sickness of the stomach and vomiting of shreds of membrane, these symptoms being quickly followed by prostration and death. In some of these cases the results may have been due to blood poisoning, but in others I believe death was the result of the stomach affection.

Among other pathological changes that may be noticed as having an important bearing on the prognosis and treatment of diphtheria, is that of albuminuria, a weakened muscular condition of the heart, and a toxic condition of the blood. Marked swelling of the neck indicates a severe or malignant form of the disease.

In the treatment of diphtheria, two important objects are to be arrived at: the first to combat and control the local affection as quickly as possible, in order to prevent as far as practicable the absorption of the poisonous deposition; second to endeavor to neutralize and destroy the poisonous particles already absorbed, and thus reduce to a minimum the deleterious effects upon the general system, at the same time supporting the strength of the patient until the crisis is passed.

Recognizing it as a specific and infectious disease of a parasitic nature, the rational and common-sense course of treatment would be, if possible, the destruction of the micrococci, before their full baleful effects are accomplished; but the fact that the constitutional symptoms follow so closely the local affection, makes it in the majority of cases impossible thus to check its progress; yet, though it is claimed by most leading authorities that it is impossible by any means in our power to annihilate the infectious principle, however thoroughly the local application may be made, the object aimed at in all scientific investigation into the etiology of diphtheria, should be the

discovery of a specific remedy, one possessing the power to destroy the vegetable organism.

In this connection, I desire to refer to Dr. Alfred Carpenter, who in the *British Medical Journal* of March 1, 1884, claims to treat the disease on scientific principles, by destroying the parasites in the following manner—he says: “I apply the powder of washed sulphur to the throat very frequently, blowing it into the fauces and applying by means of a brush, with a little glycerine or honey, alternating the application with a little sulphurous acid in solution.”

Bartholow highly recommends the use of washed sulphur, applied by an insufflator.

Topical applications to the affected parts I consider of great importance. Caustic applications, however, should be discarded, as their utility is doubtful, and injurious effects are likely to ensue from the mechanical irritation produced.

The local applications relied upon by myself are equal parts of the tincture of the chloride of iron and glycerine, applied with a mop; also carbolic acid and glycerine applied in the same manner.

Where the patient is old enough to gargle, the following is one of the most valuable combinations that can be employed:

R.	Acid. lactic,	gtt. xx. to xxx.
	Sps. rectific,	$\frac{2}{3}$ ijs.
	Glycerinæ,	$\frac{3}{4}$ ss.
M.		
S.	—Gargle frequently.	

The lactic acid has a solvent effect upon the false membrane.

One of the most valuable and indispensable local remedies at our command is that of hot medicated vapor. My manner of using it is in the form of hot tea, to which twenty or thirty drops of carbolic acid is added to a pint of the tea. In malignant cases this should be made use of every half hour, and continued from ten to fifteen minutes at a time. Its advantages are that it excites an abundant production of the pus, thus hastening the detachment of the false membrane, while at the same time we have the benefit of the antiseptic effects of the carbolic acid.

The vapor of slaking lime is highly recommended from the author's experience. Also ice. Warm poultices around the neck are believed to benefit the swollen glands and encourage suppuration.

As constitutional remedies, the following are recommended: Tincture of the chloride of iron, quinine, chlorate of potash, quinine in antipyretic doses when fever is high.

Pernanganate of potash has been used with success by the author.

The carbolic acid and iodine treatment advocated by Bartholow is endorsed as a rational mode of treatment.

Alcoholic liquors are recommended as valuable to prevent systemic infection, and for their stimulating and supporting qualities. They should be employed early and continued throughout, the quantity used to be regulated by the special demands of each case. In the malignant form of the disease, they cannot be dispensed with.

Stress is laid upon the importance of proper nourishment, the most reliable articles of diet

being milk and animal broths; the former should be used as the chief drink.

In the local treatment of laryngeal diphtheria, great reliance is placed upon hot medicated vapor, as already spoken of, and slaking lime, used frequently and persistently, also nauseants and emetics. The general treatment is similar to that already recommended.

(Concluded in next number.)

Infanticide in France.

A report has been recently made to the President of the French Republic, in which it appears that in 1882 legal proceedings were taken with respect to 171 cases of infanticide, 19 abortions, and 177 of what is termed the suppression or exposition of infants. The report then goes on to explain that the proportion of acquittals for each of these crimes amounts to 42. 55, and 61 per cent. respectively. As we may be morally certain that nearly every one of the accused was in reality guilty, the enormous proportion of acquittals must seem inexplicable to those who are not intimately acquainted with the conditions of French society. Just, however, as this official report was in course of publication, a seamstress, living in a garret in the Boulevard Voltaire, committed suicide by means of charcoal fumes. The following words were found on the mantelpiece: “I die because I am abandoned at the moment I am about to become a mother.” This simple incident explains the statistics we have quoted. The search for proof of parentage is forbidden by the French law, and French juries, knowing that the law gives no protection to betrayed and abandoned women, cannot be made to convict, even where the guilt is patent.

Medical Society of New Jersey.

The next annual meeting of the Medical Society of New Jersey will be held in the Stockton House, at Cape May City, on Tuesday and Wednesday, June 10–11, 1884. The annual address by the president, Dr. S. Wickes, will be delivered on Tuesday evening. A complimentary train for the physicians and their families will leave Camden for Cape May on Tuesday at 12 o'clock m.

Orange, May 10.

WM. PIERSON, Sec'y.

Items.

—A testimonial dinner will be given to Professor Alfred Stillé, at the Bellevue Hotel, in this city, May 22.

—Dr. Robert T. Edes has been appointed to fill the Chair of Clinical Medicine in Harvard University, made vacant by the death of Dr. Calvin Ellis.

—Prof. Cantieri, of the Medical Clinic at Siena, relates two cases of large ovarian cysts, which were completely cured by intra-cystic injections of tincture of iodine.

—The New York Cancer Hospital is reported to have received a gift of \$200,000 from Mr. John Jacob Astor, together with a number of smaller sums from others.

—Of the 37,672,048 inhabitants of France, 1,101,090 are foreigners, of whom 432,265 are from Belgium, 240,733 from Italy, 81,986 from Germany, 73,781 from Spain, 66,281 from Switzerland, and only 37,006 from the British Isles. The number of naturalized foreigners is only 77,046.

—A Summer Hospital for Children, designed to accommodate about thirty patients, is in contemplation by the people of Rochester, to be built on the shore of Lake Ontario.

—Unwholesome wells in Brooklyn, to the number of ninety-two, have been ordered to be closed by the Board of Aldermen, having been condemned by the Board of Health.

—Prof. Nussbaum recommends a few drops of oil of cloves to be dropped in the towel or apparatus used for the administration of chloroform, in cases where the chloroform is disagreeable.

—The Contagious Cattle Diseases Bill, providing for the "Bureau of Animal Industry," has passed the United States Senate with some amendments, chiefly the reduction of the appropriation to \$150,000.

—In the *Australian Medical Journal* Dr. Walsh reports a case where, twenty-nine days after the birth of a child, a second one was born. The woman had been attended by a midwife. She had made a good recovery, had nursed the first child, and was perfectly unaware meanwhile that she carried a second in utero.

—M. Abel Damour has succeeded in obtaining information of thirty women who have recovered from Porro's operation. In twenty-two cases, the catamenia ceased entirely, and nothing particular was noticed at the time of the period. Professor Porro observed once a swelling of the pedicle and a mucous discharge from the scar. In the remaining seven cases, reported by various authors, hemorrhages took place at the time of the catamenia from the vagina, rectum, bladder, nose, or lungs. Dr. Ramello's patient, who was operated on in July, 1880, suffers every month from slight epistaxis and headache.

—The death-rate of Russia is the highest in Europe. This is attributed to the paucity of medical men, and the habits of the rural population. According to late returns, the average duration of life is only 26 years, and the mortality among infants is frightful. More than 60 per cent. of infants die before they reach their fifth year, and nearly 2,000,000 children perish every year. Of 8,000,000 boys, only 3,770,000 attain the age of military service—that is to say, their twenty-fifth year; and of these at least 1,000,000 are found, by reason of shortness of stature and weakness of body, to be unfit for military duties.

—The fourth annual report of the Central Sanitary Bureau of the Japanese Government covers the year July 1, 1878–9, and contains much curious information. The number of medical students in public schools and hospitals was 4,313, but only 2,868 were pursuing a strict course. Licenses were granted to sell nearly 5,000 different kinds of patent medicines; yet this number represents a large falling off since the year before. As in the case of our "bitters," venders carried on a profitable trade in sake without paying the wine

tax, by mixing with ordinary Japanese wine a small quantity of some medicament.

Personal.

—Dr. J. D. Y. Madeira (class 1883 Jefferson Medical College) has located at Grantville, Dauphin county, Pa.

MARRIAGES.

AYRES—ROE.—At the residence of the bride's uncle, Mr. W. I. Preston, 71 Pierrepont street, Brooklyn, N. Y., on Wednesday, April 23, 1884, by the Rev. J. O. Worth, H. Messenger Ayres, M. D., and Miss Ida Laura Roe, daughter of Mrs. Worth.

BOWSER—M'FARLAND.—At the parsonage, Poughkeepsie, N. Y., January 16, 1884, by the Rev. C. W. Millard, Mr. Seward L. Bowser, of Martinsburg, Pa., son of Dr. I. N. Bowser, and Miss Ida L. M'Farland, of Poughkeepsie, N. Y.

BOWMAN—WININGS.—At Bloomington, Neb., April 18, 1884, by the Rev. T. A. Hamilton, Dr. Fred. Bowman, formerly of Chicago, Ill., and Miss Beckie M. Winings, formerly of Westmoreland county, Pa.

BULLARD—HUPP.—AT Wheeling, Va., April 23, 1884, Dr. R. H. Bullard and Miss Annie L. Hupp, daughter of Dr. Jno. C. Hupp.

CONRAD—CAMP.—At St. Andrew's church, New York city, April 29, 1884, by the Rev. Dr. Francis Loddell, J. Reed Conrad, M. D., of Philadelphia, and Miss Genie E. V. Camp, of New York city.

DANIEL—McDONALD.—At the residence of the parents of the bride, April 29, 1884, Dr. David H. Daniel, of Otwell, Pike county, Ind., and Miss Minerva E. McDonald, of Portersville, Dubois county, Ind.

DAVIDSON—CRAVENS.—At Madison, Ind., April 30, 1884, Dr. Wm. R. Davidson, of Evansville, Ind., and Miss Elizabeth Gardiner Cravens, of Madison.

HARE—PEMBERTON.—At St. Luke's church, in this city, Thursday, May 8, 1884, by the Right Rev. Wm. H. Hare, assisted by the Right Rev. M. A. de Wolfe Howe and the Rev. Dr. Hare, Dr. Hobart Amory Hare and Rebecca Clifford, daughter of Clifford Pemberton, Esq.

HUDNUT—IRVING.—At Central church, Orange, N. J., April 30, 1884, by the Rev. D. Irving, D. D., assisted by the Rev. Albert Yeomans, D.D., Dr. Frank P. Hudnut and Charlotte Elizabeth Irving, daughter of the officiating clergyman.

JACOBUS—BURKE.—At Mattison church, Bayonne, N. J., Wednesday afternoon, April 23, 1884, by the Rev. Thomas H. Jacobus, assisted by the Rev. C. S. Woodruff, Atwood E. Jacobus, M. D., of Franklin, N. J., son of the officiating clergyman, and Miss Jennie L. Burke, daughter of J. T. Burke, of Bayonne, N. J.

MAYER—LEE.—At the residence of the bride's mother, Covington, Ky., April 24, 1884, by the Rev. Mr. Jefferson, Dr. Chester A. Mayer and Mattie Lee, daughter of the late W. M. M. Lee.

RILEY—O'PRY.—At the residence of the bride's brother, Capt. J. T. O'Pry, in New Orleans, April 10, 1884, Dr. Robert L. Riley, and Miss Sallie O'Pry, both of New Orleans.

DEATHS.

BANKER.—In Enfield Vt., April 21, 1884, W. W. Banker, M. D., aged fifty-three years.

COOKE.—At Adams, Ind., April 19, 1884, Dr. J. Mills Cooke, aged forty-nine years.

JONES.—In Evansville, Ohio, April 30, 1884, Dr. H. G. Jones, aged fifty-nine years and nine months.

MEREDITH.—At Abilene, Kansas, April 28, 1884, Dr. L. Phil Meredith, formerly of Cincinnati.

OWEN.—In Cincinnati, Ohio, after a short illness, Thursday, May 1, 1884, at 2 p.m., Dr. Jesse Owen, in the sixty-ninth year of his age.

SKINNER.—At Hartford, Conn., May 10, 1884, suddenly, Dr. Thomas H. Skinner, of this city.

A CONTRIBUTION TO THE OPERATIVE TREATMENT OF PURULENT PLEU- RAL EFFUSIONS.*

BY EDWARD T. BRUEN,

Physician to Philadelphia Hospital, and Assistant Physi-
cian to University Hospital, Demonstrator of Clinical
Medicine University, Physician in Out-patient Depart-
ment in Children's Hospital, and Lecturer on Pathology
in Women's Medical College:

AND J. WM. WHITE,

Surgeon to Philadelphia Hospital, Assistant Surgeon to
University Hospital, Demonstrator of Surgery and Lec-
turer on Operative Surgery in University.

The following paper is based upon thirteen cases of empyema treated since 1877 in the Philadelphia Hospital, and in that of the University of Pennsylvania. They are selected from a number, because their history has been followed closely throughout. In two of these cases resection of the ribs was practiced; one of them will be subsequently detailed, and the portions of ribs removed will be exhibited. A third case, an adult Italian with an empyema of three weeks' standing, was treated by aspiration, with subsequent introduction of a drainage-tube, which was removed within three weeks with a result of perfect recovery. A fourth case, also an Italian, with purulent effusion dating six weeks prior to operation, was treated with a single aspiration, with a result of cure. The history of the fifth and sixth patients will be subsequently described; of the remainder three are still under observation. In these last three drainage-tubes have been inserted, and the cases have been steadily improving; one of them will be presented this morning. Four other cases have been entirely convalescent for

three years, but still retain an open sinus, from which there is a slight discharge.

CAUSES OF EMPYEMA.

The pleura possesses the power of very rapidly secreting pure pus; our clinical records showing instances in which purulent collections have accumulated in thirty-six hours. In some of these cases the general health had been depreciated by intercurrent disease other than pleural. In one instance in the University Hospital, aneurism was associated with old pleural adhesions; in another phthisis was the antecedent.

In children the rapid formation of pus is proverbial, and in pleuro-pneumonia the effusion is often semi-purulent. Acute pleurisy can terminate in cure, or in sub-acute or chronic inflammation, with effusion, or in the same with adhesions, or empyema.

It is important to determine the proportion of purulent formations which result from undisturbed pleural effusions.

Trousseau and writers of his day advocated paracentesis, dreading purulent transformation if treatment was delayed.

Albutt (*Practitioner*, vol. 2, '72, p. 77), writing in 1872, shared this view.

The chief predisposing condition towards the purulent transformation of undisturbed pleural effusions is lowered vitality, scrofulous constitution, and intercurrent disease.

The operation of paracentesis in serous effusions is often not practiced for fear it may favor purulent transformation. This result need not be feared, if care is exercised to prevent the admission of air or organisms within the chest, and if at the same time clean antiseptic instruments are used. The accidental admission of air under the above circumstances is not necessarily serious. The predisposing causes of empyema consequent

* Read before the Medical Society of the State of Pennsylvania, at its meeting in Philadelphia, 1884.

upon paracentesis are similar to those which favor purulent transformation in undisturbed pleural effusions. Sero-fibrinous pleural effusion complicating phthisis is not frequent, for the pleurisy of this disease commonly consists in the effusion of dry lymph. If sero-fibrinous effusion does occur, it is readily convertible into pus. The operation of paracentesis does not increase the tendency to purulent transformation, and is positively indicated, since there is but little disposition for these effusions to be reabsorbed.

In phthisis, pleurisy occurs whenever hydro-pneumothorax is produced by rupture of the visceral pleura, and the effusion usually soon becomes purulent.

Collections of pus in the chest-wall may follow wounds of the pleura or fractures of the ribs, and peri-hepatic inflammations; or abscesses of the liver may perforate the pleura and produce empyema.

TERMINATIONS.

Empyema may last months, or years, terminating in evacuation of the pus externally through an intercostal space, or it may be evacuated through a bronchus. More rarely an empyema is evacuated through the diaphragm into the peritoneum or colon, or into the mediastinum, thence along the vertebral column as far as the psoas muscle; or through the tissues forming the abdominal wall, and so outward.

The termination of spontaneous external evacuation through an intercostal space may be preceded by periostitis with subsequent caries or necrosis of one or more of the ribs, and it is preceded by œdema of the intercostal tissues.

EFFECTS OF A PLEURAL EFFUSION UPON THE LUNG.

1. The lung may be compressed until the air is absolutely expelled and the lung itself is flattened into a small space against the vertebral column, occupying an area mostly in the scapular region, sometimes not larger than the palm of the hand.

2. The fluid may force the lung upward, so that we may outline it anteriorly, perhaps so low as the second rib, and the lung occupies a variable area of the scapular region.

3. The lung may be bound down to any portion of the chest wall, or flattened upon the diaphragm. The substance of the lung may be hep-
atized, or the compression may result in complete atrophy of the lung.

DIAGNOSIS OF EMPYEMA.

The diagnosis of empyema presents the usual group of physical signs indicative of non-purulent pleural collections. The crucial test is by

puncture; for large collections of pus may persist in the chest with an abnormal temperature, yet without the range characteristic of collections of pus. The cases on which these observations have been made were usually those of chronic pulmonary and pleural disease, in which the pleuræ were thickened and indurated. The diagnostic puncture can be effected by a hypodermic syringe attached to a needle rather larger than the one in ordinary use.

INDICATIONS FOR TREATMENT.

In the scrofulous, or those predisposed to phthisis, it is difficult to say how long the lung may be compressed, and yet, after recovery, dilate so as to fill the chest when the pressure is removed. The healing process in a pleural cavity after effusion, whether serous or purulent, occurs through the medium of adhesions of the inflamed pleural surfaces.

Every movement of the chest parietes, then, drags the surface of the lung with it. During the persistence of the fluid the degree of motion is small, for the ribs, pressed out by an excessive quantity of fluid, are prevented from rising or falling, whilst the distension of the chest diminishes the elasticity and favors paralysis of the intercostal muscles. When the fluid is evacuated or absorbed, the character of the respiratory movements is improved, and they diminish in frequency as well as in shallowness. The lung being now adherent, is dragged by the ribs in all their increasing movements, and as the lung expands the adhesion to the chest wall increases. Each fresh expansion of the lung results in further adhesion to the costal surface, which then acquires more power over the lung to promote its return to the normal state.

Some authors* contend that air admitted into the pleural sac is opposed to the healing process of an empyema. In reply to this it may be said that the forces of expansion of the chest, are the column of air inspired, the elasticity of the thoracic parietes, and the action of the respiratory muscles, assisted by the natural tendency of the visceral pleural surface to adhere to the costal pleural surface by an action similar to that seen in a boy's sucker. The opposing forces are the elasticity of the lungs, and possibly the small amount of air contained within the pleural cavity. These latter forces are manifestly inconsiderable, when compared with the forces inflating the lung, and the granulating pleural surfaces will naturally tend more readily to adhere than the physiologically smooth pleural surfaces. With this allusion to the method by which an empyema is healed,

* Cabot, Boston Med. and Surg. Jour., August 16, 1883.

and in view of the danger of prolonged compression of the lung under these circumstances, added to the plain general principles of surgical experience in the treatment of purulent matter in the pleural sac, we submit the following indications for treatment:

Purulent effusion should be evacuated by careful aspiration as soon as recognized. The tubing and needles should be first immersed a few minutes in carbolyzed boiling water. The subsequent treatment in children and adults differs. In the former a cure may be accomplished by one or two aspirations. An almost indefinite list of cases outside of our own experience could be submitted to attest this point.* In children, when aspiration fails a free incision into the chest is often sufficient.†

Drainage-tubes can sometimes be disregarded in very young children, because their chest-walls are so elastic that collapse of the cavity and its obliteration by adhesions is perfectly practicable. As the age of children increases the state of their chest-walls approximates that of the adult, and after the age of ten years the treatment is usually identical. This treatment should be a preliminary trial of aspiration, but absorption failing to occur, a prompt recourse must be had to drainage by the introduction of a tube into the chest through an intercostal space, in a manner to be hereafter described. This tube should be sufficiently large to secure constant free drainage and thus prevent the stagnation of the pus and its decomposition. If thorough drainage is accomplished, the use of disinfectants by intra-thoracic injections is rendered unnecessary, unless a stimulant to the granulating surface is required. In this latter case the usual surgical principles should govern the character of the solution and its strength, the writer's preference being given to Lugol's solution.

When purulent pleural effusions occur in the course of phthisis, or in this disease when complicated with pneumothorax, the propriety of operative treatment has been already indicated.

Resection of the ribs should be practiced upon indications drawn from anatomical considerations.

If the opening through the intercostal space fails to provide sufficient drainage, or if the discharge continues three or four months with a deleterious effect upon the general health, and a physical examination shows that the pleural cavity, although diminished in size, is still so large that it is improbable that obliteration of the cavity can occur, resection of one or more ribs should be practiced. This operation offers freer access to the cavity of the pleura, and also allows the chest wall to collapse to such an extent as to produce obliteration of the cavity by permitting its walls to approximate one another.*

Finally, with reference to the withdrawal of the drainage-tube. This should be done as soon as a physical examination shows that the lung has descended sufficiently to allow approximation of the surfaces of abscess. When this has occurred, the presence of a drainage-tube in a sinus becomes a source of irritation. The sinus can be packed with lint, and treated on general principles.

Having decided in any case that no disposition exists to spontaneous closing of the cavity after the performance of paracentesis alone, and that it is necessary to supplement this operation by one looking to the thorough, complete, and *continuous* drainage of the suppurating region, the question which presents itself is how best to secure this drainage.

This, it seems to us, after a careful review of the matter from both a clinical and an anatomical standpoint, is not a difficult one to answer. The general principle which applies to the treatment of extra-thoracic abscesses applies here. To do away with the possibility of accumulation of pus, to obviate the necessity for frequent and often mischievous interference with the granulating inner surface of such cavities by injection or irrigation, the most dependent point consistent with safety to neighboring tissues or organs is always selected for the puncture.†

This point is to be found on the right side in the seventh intercostal space, and in a line with the posterior border of the axilla. On the left side it should be one space lower, and in the same line. More posteriorly the ribs and intercostal spaces

Homen's rev. of Estlander's, Management of Empyema by Resec. of Ribs. Arch. für Klin. Chir., Berl., 1881; also Korting, in Puncture Incision, Resec. and Antiseptic Inject.

†It has been stated (Powitt, op. cit., p. 144) that "the only point of resemblance between an empyema and an abscess is the pus which each contains." But for our purposes the above establishes the parallel quite sufficiently, even admitting it to be true, which we are not inclined to do.

are covered by large masses of muscle, the intervals between the ribs are greatly diminished; the intercostal arteries running more horizontally than the ribs themselves, cross the spaces diagonally, and are thus exposed to injury. More anteriorly the higher level of the diaphragm not only exposes it to injury during the operation, but by exercising pressure on the drainage-tube interferes with its satisfactory action; and then, too, the opening is not by any means in the most dependent position in the usual posture of a patient after this operation.

The eighth intercostal space on the left side, and the seventh on the right, may be most easily found by tracing outward the seventh rib, which is the lowest attached directly to the sternum, and which forms the upper boundary of one of these spaces and the lower boundary of the other. Or the rule given by Mr. Powitt may be adopted, viz.: Mark on the skin the position of the angle of the scapula, when the arm is by the side and also when the arm is raised above the head; one inch below the middle of the line drawn between these two points will be found the desired spot. It should be said, however, that, though this leads accurately to the eighth interspace, the "spot" described by him is in our judgment somewhat too far posterior, and, at least from the operative point of view, is open to the objection above stated.

The claim which has been advanced that because a certain number of cases of empyema have been opened in the fifth interspace anteriorly, that point should be selected for the performance of the operation, seems to us altogether without rational foundation; first, because only a small minority of the cases of empyema open spontaneously, and not by any means all of them at that interspace; and next, because the general principle which regards the workings of "nature" in such cases as a guide to the surgeon is a misleading and unsound one, which, if adopted in other cases, would often lead to serious or fatal mistakes.

Having selected the spot for the operation, its performance is extremely simple and devoid of danger. With an ordinary bistoury an incision should be made opposite the upper border of the rib, pruning the lower limit of the interspace an inch to one and a half inches in length, and extending at first through the skin and superficial fascia; the deeper fascia and the intercostal muscles should then be divided on a dissector; the pleural wall, usually found thickened and unnaturally dense and resisting, picked up with the forceps, nicked and divided to an extent equal to

the external incision, and the drainage-tube inserted. The division of the pleura will usually be followed by some hemorrhage, often quite free for a few moments; but it is almost never dangerous, comes chiefly from the granulations on the inner surface of the membrane, and subsides spontaneously. The outer end of the tube should be cut off parallel, and on a level with the surface of the chest-wall should be threaded with a silver wire or with a long thread of waxed hemp or silk, so that it may be easily recovered if it should pass into the pleural cavity. A long projecting end of drainage-tube is objectionable, because it is liable to become compressed by the dressing or by the clothing, so as to almost or quite occlude it. The same objection applies to the plan of hooking a drainage-tube around a rib and tying the ends together, one which adds slightly to the severity of the operation, necessitating another wound, and at the same time leaves the tube in a position much exposed to pressure and occlusion.

The operation should be conducted with attention to antiseptic details; and we would recommend as an excellent dressing in which to receive the discharge, a thick layer of salicylated or borated cotton, over which may be placed some layers of carbolized gauze and macintosh.

If the pus escaping from an empyema cavity which has been treated in this manner remains sweet and odorless, if there is no evidence of accumulation, and, most particularly, if the cavity seems to be diminishing in size, no further local or operative treatment is either necessary or justifiable. Attention should be paid merely to the general hygiene and nutrition of the patient, and to the perviousness and efficiency of the drainage-tube.

If, however, in spite of these precautions, the pus is found to become fetid or ammoniacal, it will be proper, recognizing that this condition, in the vast majority of cases, results from imperfect discharge, and that no use of a septic or disinfectant lotion or injection can possibly remove it, to make a second and still lower opening through the chest wall, and carry a drainage-tube directly through from one to the other, allowing its curve or belly to rest upon the floor of the cavity. This may readily be done by gently passing a long, blunt-pointed probe from the original opening across the base of the chest, carefully avoiding the diaphragm, of course, and the lung, if it is at the base of the chest (a somewhat unusual occurrence), and making the end of the probe prominent in the opposite side, in the lowest available intercostal space; then cutting down

upon it just as in making the first opening, it may be drawn through, bringing with it the drainage-tube, which should now be secured at both ends.

This will usually be followed by a marked change in the character of the discharge and in the condition of the patient; not infrequently by a rapid diminution in the quantity of the pus and in the size of the cavity, which may finally become obliterated, even although with the imperfect drainage afforded by the opening it has remained stationary for a long period.

We have had two cases which illustrate this statement, but which it is not necessary to detail, as they are the ordinary cases of empyema, with the usual symptoms, and the operations were performed after the manner just described.

In a certain proportion of cases, however, this treatment proves unavailing.

Two or three months elapse, the cavity remains as large as ever, and the patient is losing in general health and strength. It then becomes advisable to adopt some means to lessen the size of the cavity, and with it the extent of suppurating surface, and at the same time time favor the formation of those adhesions which, as has already been observed, are so useful, if not essential, in drawing the lung down and aiding in its expansion and the obliteration of the cavity.

In such a case, the operation of excision of a portion of the ribs on the affected side becomes justifiable. By permitting of the partial collapse of the chest wall on that side, it approximates the walls of the cavity, reduces its size, aids in the formation of adhesions, lessens the amount of pus secreted, and, as it may be performed with little or no danger to the patient, is evidently strongly indicated on theoretical grounds alone. And the results of the recorded operations which have been performed in suitable cases, amply justify the *a priori* view. The rules for the operation may be formulated as follows:

1. The portions of the ribs selected should be those between their angles and their sternal attachments. Posterior to this, they are less movable and are so close together that the difficulties of the operation are greatly increased.

2. Those ribs between the third and tenth should be selected which most accurately overlie the cavity.

3. The number of ribs operated upon should be proportionate to the extent of the cavity.

4. The length of the pieces excised should be proportionate to the depth of the cavity.*

*See paper by Dr. A. Homen. *Langenbeck's Archiv für Klin. Chir.*, Band xxvi., Heft. 1, p. 151.

5. The operation should be done aseptically and subperiosteally, and when so performed is almost without danger; and even in cases where large portions of ribs are removed, is followed by no permanent loss of function in the external respiratory muscles of that side.

In the case of a patient from the medical wards of Blockley Hospital, suffering from a large empyema, involving the whole pleural cavity of the left side, we performed this operation in the presence of several of our colleagues, of Dr. D. Hayes Agnew, and of the medical class.

It having been decided to remove portions of the fifth, sixth, and seventh ribs on the left side, a curved incision, ten inches in length, was carried through the overlying tissues, beginning about an inch above and within the nipple, and terminating on the axillary line at about the ninth interspace. A large horse-shoe flap, consisting of skin, subcutaneous tissue, and pectoral muscle, was reflected upwards, and the ribs exposed. A few small vessels were tied, and then the periosteum was reached from the ribs with an ordinary elevator; an eyed probe, with an abrupt curve and carrying a chain-saw attached, was passed around each rib separately at two places, and the requisite portion removed. By exercising great care in denuding the under surfaces of the ribs, employing for that purpose a gouge curved on the flat, the intercostal arteries were pushed inward with the periosteum, and it was not necessary to tie a single one of those vessels.

Two inches were removed from the fifth rib, two and a half from the sixth rib, and three from the seventh rib.

A large drainage-tube was inserted into the cavity, the external wound bandaged together by wire sutures, and an aseptic dressing and compress applied. There was absolutely no unfavorable symptoms after the operation. The greatly-improved drainage (which is one of the conspicuous benefits resulting from this operation, and is almost of itself a sufficient indication for its performance), caused an immediate improvement in the character of the discharge. The external wound united by first intention. The general

health and strength of the patient improved greatly, and the cavity notably diminished in size.

The patient died two and a half years later of an acute bowel trouble, having outlived the average period of such cases at Blockley, and being then apparently on the road to complete recovery.

This case and the method of operation may be taken as typical, and the result is even less favorable than may be anticipated in the large majority of cases.

Our conclusions, then, may be formulated as follows:

1. Those cases of pleural effusion which are most likely to become purulent, and therefore to need operative treatment, are those occurring in persons of lowered vitality, scrofulous diathesis, or who suffer from intercurrent disease.

2. The diagnosis of empyema can only be made with absolute certainty by puncture and inspection of the fluid. This method of examination need not be delayed for fear of favoring the purulent transformation of a serous fluid, if proper aseptic precautions are observed.

3. In young children, one or two aspirations will often suffice for a cure. If these fail, simple incision of the chest without the introduction of a drainage-tube is often all that is requisite.

4. In older children, and in adults, it is proper to aspirate once; but recovery not resulting promptly, a large drainage-tube should be inserted at the most dependent point.

5. If after this drainage is still imperfect, as shown by the fetid character of the discharge, a second opening should be made, and a tube carried directly across the base of the cavity.

6. If after a suitable delay (from two to four months) there is no disposition to permanent closure of the suppurating cavity, but if the lung has expanded sufficiently to indicate that it is capable of further descent, it would then be proper to facilitate its expansion and the obliteration of the cavity by removing certain portions of the ribs of the affected side.

7. If thorough drainage is accomplished, the use of disinfectants by intra-thoracic injections is rendered unnecessary, unless a stimulant to the granulating surface is required.

8. In cases in which the lung is at the bottom of the chest and bound fast to the diaphragm, or in which it has been so atrophied prior to aspiration that there is no possibility of reinflation, or in which it is occupied by a tuberculous or an inflammatory infiltration, this operation is contra-indicated.

A MODIFICATION OF THE SPHYGMOGRAPH, BEING A CHANGE IN THE BASE OF THE INSTRUMENT OF POND.*

BY J. H. MUSSER, M. D.,
Of Philadelphia,

Chief of the Medical Dispensary of the Hospital of the
University of Pennsylvania, Pathologist to the
Presbyterian Hospital, etc.

The object of this paper is to introduce to the members of this society for their consideration a modification of the sphygmograph which is in common use in this country—the instrument of Pond—whereby it may be rendered still more practical, and hence more frequently resorted to by the profession. This is neither the time nor place to dwell upon the merits of the various instruments that have been devised, nor to discuss the mechanical and physiological questions which involve a correct appreciation of the action of the sphygmograph. A knowledge on your part of these questions will be taken for granted by the writer. In addition to asking your attention to the advantages of the modified base, a few moments will be taken up with discussing questions appertaining to the practical application of the instrument.

The sphygmograph, it will be admitted, has not become one of the indispensable articles of a physician's armamentarium, as its promoters and admirers had hoped for. This is readily understood, and depends upon many causes. But the chief of these causes is undoubtedly the length of time required to secure a proper tracing. Again, various instruments record various tracings, and hence there is a lack of uniformity, making comparative study of your own with the work of others almost impossible. The lax rules about regulating pressure have been so confusing that the operator would scarcely be able to select the proper one from the many that could be secured by varying degrees of pressure. Had we an instrument by the use of which these obstacles would be reduced to a minimum, undoubtedly sphygmography would grow in favor, and assume its proper relation in the diagnosis and prognosis of disease. It is confidently believed that the element of time at least will be reduced to the position of a negative opponent, by the proposed change in the instrument, while for accuracy its value will be enhanced.

The sphygmograph of Pond is generally conceded, in this country, to be the most readily applied. Simple in construction and mechanism,

*Read before the Medical Society of the State of Pennsylvania at its meeting in Philadelphia, 1884.

tracings can be secured by it more rapidly and with less discomfort to the patient, than with any instrument familiar to the writer. He has used the unmodified instrument several years, but often found bitter disappointment attend its use. The writer suggested to his former student and friend, Dr. H. N. Mateer, now of Wooster, Ohio, to pursue investigations with this instrument, for the purpose of incorporation in a thesis presented for the degree of M. D.* He, too, was often chagrined at meeting defeat in his designs. By careful study and great patience, he devised the changes which are presented to you to-day. To his genius are we indebted for the improvement, and to his generosity the writer is indebted for the pleasure of introducing it to you, for which he makes grateful acknowledgments.

The essential portion of a sphygmograph, in considering its merits, is that which is applied to the vessel, viz.: the base. It should be so made as to closely hug the artery, without exercising such undue pressure as would modify its calibre, in order that the arterial and blood wave should be properly transmitted to the indicator. A study of the anatomical relations of the radial artery, at its most accessible point, will show at once the character of base required. This point is where the artery rests on the bone, between the styloid process of the radius and the radial flexors of the carpus. The distance from the process to the flexor is one-fourth to three-eighths of an inch, in many cases even less. As the artery is on a lower plane than the upper level of these firm structures, it will be seen, and so Dr. Mateer reasoned, that the base or portion to be adjusted to the artery must be three-eighths of an inch, or even less, in width. The base of the Pond instrument is five-eighths inches wide, and it is, therefore, both in theory and in practice impossible to take tracings in very many instances with it.

It is true that in those cases in which the artery is superficial or the tissues are relaxed, admirable tracings can be secured with the old base—true, too, that tracings can be secured from any wrist; but it is held that they are secured with such high pressure that accuracy is sacrificed, or they are not intelligible. The base of the Pond machine was made for general work—to write tracings of the larger vessels, the heart, and aneurisms, etc.—but in so doing, the special work of writing tracings of the radial was sacrificed.

The wood cuts illustrate the differences in the bases, No. 1 representing the old, No. 2 the new

FIG. 1.

base. A further description is necessary. It is made of metal-brass, and is firmly attached to the cylin-

FIG. 2.

der of the instrument, yet it is readily removed

*For this thesis a prize of \$50 was secured by Dr. M. from the University of Pennsylvania.

It is longer than the old base, and tapers towards the distal end. This end is round, $\frac{3}{8}$ in. in diameter, grooved to the depth of $\frac{1}{8}$ inch. This groove was made by Dr. Mateer, so that it could be more closely applied to the vessel, with the least possible pressure. The advantage of fixation of the vessel by the groove is also gained, so that the tracing is made more regular. The increase in length of the base necessitated a corresponding increase in the length of the central transmitting rod, while the diminution of its size rendered a proportionate lessening of the diameter of the flat disk attached to the distal end of the rod. Instead of the usual rubber cap, a small rubber band is made to stretch across the aperture of the base parallel to the groove. As noted above, the base can be removed at will, and the old base reapplied, for the purpose of taking those tracings for which it is fitted.

It is claimed for the modification, greater ease and rapidity of application of the instrument, and greater uniformity and clearness in the tracings. In order to more fully substantiate these claims the following illustrations of tracings, both by the old and the modified instruments, are presented:

Tracings 1 and 2, 3 and 4, 5 and 6, 18 and 23, were taken from the same individuals respectively. The persons from whom the tracings were secured were all under medical care, with symptoms of deranged circulation, save in the instance of Nos. 18 and 23. In order to correctly appre-

ciate the tracings, one should have a distinct idea of a true tracing. By a true tracing is meant one that graphically represents the action of vessel and contents, whether it (the tracing) be normal or abnormal.

The writer can substantiate the statement of Dr. Mateer, who says a normal tracing, as taken by the Pond instrument, should consist of an up-stroke, departing 10° to 15° from a perpendicular, an acute apex, and a descent at an angle of about 45° ; the descent is marked by two secondary waves of almost equal size, and the general trend of the descent is a slightly curved line, with its convexity downwards. Comparing the tracing so delineated (No. 23) with tracings by a Marey sphygmograph, one sees as much contrast as in a comparison between the "old and new base" tracings. This difference is worthy of explanation just here, in order to facilitate comparative study of tracings taken in similar forms of disease. The two forms of sphygmograph above mentioned represented two classes of instruments, and their work may therefore be compared. The lever, which is moved by the pulse, is restrained by a spring, and follows closely the movements of the vessel. The intervening rubber membrane follows the subsiding vessel in the "Pond," leaving the recording needle free to the influence of inertia. On account of this inertia, a greater height is given to the tracing, and the secondary waves are more distinctly brought out. As shown by Mateer, this same inertia causes the acute apex in the "Pond" tracing, the obtuse in the "Marey." Any one comparing tracings of these instruments, will see the uniformity of tracing and the distinctness of outline of the former as compared with those of the latter. It is, indeed, rather marvellous to be able to read correctly the ill-defined and irregular tracing of the Marey machine.

In conclusion, it seems not unbecoming to speak of the methods of ready use of the sphygmograph, and first regarding the wrist rest. Office work often will not permit one to delay long in arranging position, etc., and the writer has found that as good tracings can be secured without resort to this delay, and especially the discomfort of the patient, without the special rest as with it. As to pressure, its importance seems to be exaggerated. With Mateer, the writer studied it carefully, and we found the following formula a safe guide, one much more arbitrary than is generally given. Always apply that amount of pressure which yields the greatest amplitude to the tracing. The gauge adjusted to Pond's instrument is absurd

for it measures the pressure of the entire instrument on the wrist, enormous often with the old base. The gauge should be adjusted to the central part, which is raised by the artery. Even then its utility is doubtful. Graduated pressure is used to secure the same amplitude to a tracing—say one-half inch. The difference in pressure necessary to accomplish this in a hard and soft pulse would be equalled or surpassed by the varying resistance of the tissues surrounding the vessel.

The rate of speed of this slide is of practical moment. It should be such that the length of the tracing, horizontally, will be equal to its height, thus permitting the fullest development of all its elements. A tracing taken with the proper care, indicated by this instrument, is very legible and easy of interpretation.

A word may be said as to the value of sphygmography. As clinical studies are not within the province of this paper, they will not be detailed; the conclusions that can be drawn from considerable experience will not be out of place, however. Briefly, they are to the effect that in the diagnosis and especially the prognosis of various diseases, it is of extreme value. Especially is this true in the settlement of mooted questions connected with high tension, and the high tension diathesis, and with heart disease in its various forms, particularly in the estimation of cardiac power. In the prognosis of fevers, the sphygmograph is also of value. But withal, this only can be said that its value is great to the individual operator alone. In securing tracings, which can only be done properly after long practice, the personal equation is a most important factor. One can learn his power and know of what value his own control of the instrument is to the result of a proper treatment, which he can utilize in his judgment of the meaning of it. To another this is unknown, hence they can not interpret tracings taken by others. Therefore, the writer believes that to the operator who forms judgments of a case, its power is invaluable and increases with his experience; while, save in the conclusions, the general profession can profit but little.

In conclusion, the writer ventures to express the conviction that the modification of Dr. Mater will be of inestimable service in popularizing this valuable instrument. He feels that the judgment of the profession will be that the claims which have been presented for it are not too extravagant, and that sphygmography is materially promoted by the addition.

3705 Powelton Avenue.

WORK OF WOMEN PHYSICIANS IN ASIA.

BY MARY H. STINSON, M. D.,
Of Norristown, Pa.

(Continued from page 617.)

Medical missions are auxiliaries, whose primary object is the salvation of souls. By their reputation for medical and surgical skill, they draw the populace after them, gain their confidence and lead them to say one to another, "You need not be afraid of these missionaries. They are your friends, and have come to do you good." Rev. Mr. Corbell said, "Every attempt to get hold of a new city failed until our medical missionaries first won the confidence of the people by healing or relieving them in cases where the skill of the native physician would not avail." Rev. E. A. Moule attributed his success largely to the hospital work under the care of his associate, Dr. Galt.

Women medical missionaries are sent to break down the hitherto impenetrable barrier of caste. The late Dr. Duff, than whom none better knew the peculiar condition of Hindoo women of the upper classes, when speaking of females having a knowledge of the science and practice of medicine, said, "Would to God we had such an agency ready for work! Soon would India be moved to its inmost recesses."

There are two distinct systems of medicine in India. The Yonani or Greek is practiced by all the Hindoo doctors, called baidis, which means medical science or philosophy. They are disciples of the school of Hippocrates, who taught the Greeks their system long before the Christian era. The Yonani has been modified by the older Aryan and the newer Arabic, introduced about 700 years ago by the Mohammedan conquest. These Mohammedan doctors are called "hakoom." "These old systems, full of error and superstition, live and thrive; they are fully believed and wrought into the domestic life of the people."

Women medical missionaries have to contend with both systems, and must have the utmost confidence in their own, and a supreme courage to practice it in the face of much opposition. All confess that the English doctor has marvelous skill in surgery. It is in this that the lady physician will find her widest field of usefulness, and become the greatest blessing to humanity.

During all the past years of missions, the ordained missionaries carried certain medicines when on their circuits, preaching in the villages and out-stations, and by the distribution of which they greatly increased their audiences. Their wives had miniature apothecary shops, and were

obliged not only to medicate their own family, the children of the schools or plantations, but to give medicine to all the sick who applied for it. Thus these mission wives learned the wants of the women and children by whom they were surrounded; also, that these ministrations secured them admission where even their teachers could not gain an entrance. Consequently, they were the first to feel that women physicians were a necessity for the completion of the missionary corps.

Native Christians, English-speaking government officers, merchants, and bankers, had grown somewhat into sympathy with mission projects, as evidenced when there was an effort made to provide a way to educate native women in medicine, by one of these men saying, "It would open the doors of the zenanas as nothing else could. Besides this, you would save thousands of lives that are now sacrificed through the ignorant and bad practice of native doctors."

Another offered to bear half the expenses of educating a class of women in midwifery and medicine, if the government would grant the other half. Application was made. The government officer was in favor of granting the funds, but "there was so much opposition by medical men," and so much inevitable delay, that the gentleman who made the application withdrew the papers, and became responsible himself for the requisite amount. A class of nine women (there were men also) was opened May 1, 1869, under the supervision of Rev. J. S. Humphrey, M. D., in Nynsee Tal. After a two years' course of study, four of this class passed a creditable examination, and received certificates of fitness to practice "ordinary surgery and medicine." Early in the same year, the Macedonian cry, "Come over and help us," was heard, in an urgent appeal to the Philadelphia branch of the "Woman's Missionary Society," to send "a full-fledged woman doctor" to the mission in Bareilly, India. Here some girls had been carefully taught, hoping that they might have a chance to study medicine. They had already acquired a fair knowledge of the English language, which was necessary, as there are no words in their vernacular corresponding to technical medical terms.

Miss Clara Swain, M. D., who graduated in March, 1869, in "The Woman's Medical College in Philadelphia," was recommended to and adopted by the "Woman's Union Foreign Missionary Society." But she being a member of the Methodist Episcopal church, and "The Woman's Missionary Society" of that church having just

been organized, Dr. Swain was transferred to its care, under which she sailed November 3, 1869, and arrived in Bareilly, India, on January 20, 1870. She was received with much joy by the mission, as a direct answer to their prayers of faith. Prominent intelligent gentlemen of the neighborhood called to welcome her. One, a native who spoke English very well, said, "We need lady physicians in India very much, and I have often spoken of it to my friends, but we did not know where to look for them; as our women are uneducated, they could not study medicine. But it seems the people of the West have thought of us, and helped to meet our necessity by sending you. Light has again dawned from America." Ah! how much that word America signifies to the oppressed.

Dr. Swain was called immediately to visit women and children of all classes in the community, having had in the first six weeks after her arrival 108 patients. She was at once connected with the orphanage, and on March 1, 1870, commenced teaching medicine to a class of sixteen girls and three married women. They studied well, and thirteen of this class, on April 10, 1873, received from an examining board, two of whom were civil surgeons, "certificates of practice in all ordinary diseases."

In Dr. Swain's first annual report, we find she prescribed at the mission house for 1,225 patients. In the houses of the patients, for 250. And she said, "The way continues to open to our work. We have been called to sixteen different zenanas."

Dispensary and hospital conveniences had become an absolute necessity. But where could suitable grounds be bought, and could the society at home furnish the necessary means? were questions that caused much anxiety. A Mohammedan, Prince of Rampore, forty miles distant, owned an estate of 42 acres, well adapted for hospital purposes, adjoining the mission property. But as he had been decidedly opposed to Christianity, they had no hopes that it could be purchased for any price. However, the Commissioner advised the missionaries to ask his highness upon what terms the property could be bought for a hospital for women and children. This they did in October, 1871. To their astonishment and joy, the Nawab said, "Take it, take it. I give it to you with pleasure for that purpose." This gift was worth at least \$15,000. A dispensary building was ready for use by May 10, 1873, and the hospital completed on January 1, 1874, at a cost of \$10,350, all of which was furnished by "The Woman's Foreign Missionary Society of the Meth-

odist Episcopal Church" except \$350, collected in India.

Dr. Swain was assisted in her medical work by some of those who had received the "certificates," and by native medical students. The dispensary cards were printed in Hindoo, Persian, and Roman Urdu characters. From the 10th of May, 1873, to the 31st of December the same year, 1,600 patients were treated in the new dispensary.

Dr. Swain, when speaking of the sick in the zenanas, said, "My heart is often encouraged by their eagerness to hear and to be taught. They beg for our books, and ask us to come every day." Morning prayer to their false gods and idols is the national custom of both the Hindoo and the Mohammedan.

During 1874, fifty new families called for professional services, and all desired to have a teacher. The number of dispensary patients exceeded 3,000, with 150 outdoor patients.

Dr. Swain's reports of her work read like medical fairy tales. A friend at the mission wrote: "The Lord has had the matter of women medical missions in his own hands from the beginning. Dr. Swain is a grand success."

This minutia of the first four years' work of a woman medical missionary, without any interest of incidents, must serve for the work of all following women medical missionaries in India. All had similar trials and successes, but not to the same extent. No other woman physician in India but Dr. Swain, has taught native women students in medicine.

If time permitted, I should like to tell you of the discussions in the conferences of the missionaries from year to year, so that you might realize how slowly even some of these men grew to know the importance of female education and women's medical missions.

Not until 1872 do we find women in these conferences with papers. But in the conference in Allahabad of that year, Mrs. Winters, the wife of a missionary in Delhi, read a paper on "Female Education," and Miss Brittan one on "Zenana Missions." In the course of her article, Mrs. Winters said: "I would venture to urge the conference not to discuss the question of missions to women, but to spend the time thus saved in silent prayer to God for money, women, and, above all, love."—"I beg the conference with one voice to appeal to America, Germany, and England for aid."—"We ask for the flower of the ladies' colleges, the best nurses from the hospitals, the most devout sisters of mercy from the penitentiaries."—"We ask not an army of zenana teachers; the

best missionaries I have known have been Eurasians (Anglo-Indians) and natives. Why should we despise the workers God has put ready to our hands? We want from home a few picked women who will take the higher subjects, and train these nurses, and deepen their spiritual life."—"I left Bengal, after a four years' work, with an intense love for the Bengali women, and with the conviction that with Christianity they would become equal to the best cultivated women in the world."

Miss Brittan, in closing her address, said: "I believe the work among the women in India to be the most important mission work in India. The men had to be educated up to a certain point before they would permit their women to be taught; but now since that has been done, they are anxious to bring their women up to themselves. Depressed, debauched, and degraded as woman is here, she is an almighty power for evil. The influence of the wife is little; that of the mother, unbounded; and as long as that is only for evil, what hope can there be for the youth of India?"

At the same conference, in 1872, there were read two papers on medical missions by Rev. J. S. Humphreys, M. D., and Colin Valentine, Esq., M. D. Female doctors were discussed for the first time in conference in India. In answer to supposed impossibilities, Dr. Humphrey said: "It has been demonstrated beyond a doubt that we can educate the women even, and when educated, they may become useful and efficient practitioners."—"We need something like what is required at home, to make physicians and surgeons"—"in case of both men and women."

Dr. Valentine said: "When I first drew up this scheme for a medical missionary training institution a few years ago, there was not a single female medical missionary in India."—"No provision was made for female students. Now, however, there are female medical missionaries in the country, with a prospect of a large accession to their numbers. I would propose to the conference that the opening of female classes form part of our scheme."

Eleven years after this proposition of Dr. Valentine, we find in a Calcutta newspaper, the *Indian Witness*, of October 27, 1883, the following communication: "As there is a demand for medical Zenana workers in Northern India, it may prove an item of interest to some that the government has opened the Agra Medical School to women. A small class of native women are now in attendance. These are supplied with scholarships from the government; and under certain conditions, private female students may have ac-

cess to all the lectures, and after a course of three years, may be graduated. It should also be known that the Agra Medical Missionary Training Institution, organized through the efforts of Rev. Dr. Colin Valentine, proposes to provide scholarships for native students, male and female, who may wish to pursue a medical course in Agra. Further, the Rev. J. M. Reed, D. D., Secretary to the Missionary Society of the M. E. Church, U. S. A., proposes to be come responsible, as far as necessary, for Methodist native students, and these of either sex, who have been properly recommended may, in connection with this institution, come to Agra to attend the Medical School. We have to thank Mr. H. Dear, of Monghyr, and other gentlemen, for scholarships supporting several lads in attendance at the Medical School. But we urgently need additional funds to be used as scholarships for native Christian students of either sex who may wish to gain a medical education, and for whose maintenance no provision has been made. The new year in the Agra Medical School begins on the 1st of June, 1884."—"It is thought that scholarships for girls should be ten rupees per month, which would pay, not only for their books, clothes, and food, but also for a matron to accompany them to and from the lectures. Scholarships for the boys should be eight rupees monthly."

Rev. Dr. Scudder, M. D., in the conference of 1872, said: "I wish to add my testimony to the great value of medical missions as an evangelizing agency. I come from a medical stock, and therefore feel as if I had a right to speak in the matter. My father labored as missionary physician in India for thirty-five years, and bore testimony to the value of the medical work, regarding it as one of the best means of reaching the people. My own experience, too, extending over a period of seventeen years, is to the same effect."—"I should like to say just a word about this new movement, the introduction of medical ladies into missionary work. I am very glad to see it, and at the same time sorry to refer to the manner in which the medical students in the University of Pennsylvania and in Edinburgh disgraced themselves by their opposition to lady students. It is gratifying to know that this has been overthrown, and that the ladies are taking the place they deserve to occupy."—"They can enter into families where male physicians are forbidden access. I do not mean to say that the latter are entirely excluded; but, on the other hand, there are many cases in which native women would rather die than admit a male physician."

MEDICAL SOCIETIES.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

(Continued from page 622.)

In the cases of *chronic meningeal syphilis* which have come under my observation, most usually after a greater or less continuance of prodromes, such as have been mentioned, epileptic attacks have occurred with a hemiplegia, or a monoplegia, which is almost invariably incomplete, and usually progressive; very frequently diplopia is manifested before the epilepsy, and on careful examination is found to be due to weakness of some of the ocular muscles. Not rarely oculo-motor palsy is an early and pronounced symptom, and a marked paralytic squint is very common. Along with the development of these symptoms, there is almost always distinct failure of the general health, and progressive intellectual deterioration, as shown by loss of memory, failure of the power to fix the attention, mental bewilderment, and, perhaps, aphasia. If the case convalesce under treatment, the amelioration is gradual, the patient traveling slowly up the road he has come down. If the case end fatally, it is usually by a gradual sinking into complete nerve paralysis, or the patient is carried off by an acute inflammatory exacerbation, or, as I saw in one case, amelioration may be rapidly occurring, and a very violent epileptic fit produce a sudden asphyxia. In this form of cerebral syphilis, death from brain-softening around the tumor is not infrequent; but a fatal apoplectic hemorrhage is rare.

The clinical varieties of cerebral meningeal syphilis are so polymorphic and kaleidoscopic, that it is almost impossible to reduce them to order for descriptive purposes. Prof. Fournier separates them into the cephalic, congestive, epileptic, aphasic, mental, and paralytic, but scarcely facilitates description by so doing. Heubner makes the following types:

"1. Psychical disturbances, with epilepsy, incomplete paralysis (seldom of the cranial nerves), and a final comatose condition, usually of short duration.

"2. Genuine apoplectic attacks with succeeding hemiplegia, in connection with peculiar somnolent conditions, occurring in often-repeated episodes; frequently phenomena of unilateral irritation, and generally at the same time paralyzes of the cerebral nerves.

"3. Course of the cerebral disease similar to paralytica dementia."

In regard to these types, the latter seems to me clear and well-defined, but contains those cases which I shall discuss under the head of cortical disease.

Meningeal syphilis as seen in this country does not conform rigidly with the other asserted types, although there is this much of agreement, that when the epilepsy is pronounced, the basal cranial nerves are not usually paralyzed; the reason of this being that epilepsy is especially produced when the gummatous change is in the ventricles or on the upper cortex. In basal affections, the epileptoid spells, if they occur at all, are usually

of the form of petit mal; but this rule is general, not absolute. The apoplectic somnolent form of cerebral syphilis, for some reason, is rare in this city; and it seems necessary to add to those of Prof. Heubner's, a fourth type to which a large proportion of our cases conform. This type I would characterize as follows:

4. Psychological disturbance without complete epileptic convulsions, associated with palsy of the basal nerves, and often with partial hemiplegia.

The most satisfactory way of approaching this subject is, however, to study the important symptoms in severally, rather than to attempt to group them so as to make typical, recognizable varieties of the disease; and this method I shall here adopt.

Headache is the most constant and usually the earliest symptom of meningeal syphilis; but it may be absent, especially when the lesion is located in the reflexions of the meninges which dip into the ventricles, or when the basal ganglia is small and not surrounded with much inflammation. The length of time it may continue without the development of other distinct symptoms is remarkable. In one case (Book Y, p. 88, 1879), at the University Dispensary, the patient affirmed that he had had it for four years before other causes of complaint appeared. It sometimes disappears when other manifestations develop. It varies almost indefinitely in its type, but is, except in very rare cases, at least so far paroxysmal as to be subject to pronounced exacerbations. In most instances it is entirely paroxysmal; and a curious circumstance is, that very often these paroxysms may occur only at long intervals; such distant paroxysms are usually very severe, and are often accompanied by dizziness, sick stomach, partial unconsciousness, or even by more marked congestive symptoms. The pain may seem to fill the whole cranium, may be located in a cerebral region, or fixed in a very limited spot. Heubner asserts that when this headache can be localized, it is generally made distinctly worse by pressure at certain points, but my own experience is hardly in accord with this. Any such soreness plainly cannot directly depend upon the cerebral lesion, but must be a reflex phenomenon, or due to a neuritis. According to my own experience, localized soreness indicates an affection of the bone or of its periosteum. In many cases, especially when the headache is persistent, there are distinct nocturnal exacerbations.

It will be seen that there is nothing absolutely characteristic in the headache of cerebral syphilis; but excessive persistency, apparent causelessness, and a tendency to nocturnal exacerbation, should in any cephalalgia excite suspicion of a specific origin; a suspicion which is always to be increased by the occurrence of slight spells of giddiness, or by delirious mental wandering accompanying the paroxysms of pain. When an acute inflammatory attack supervenes upon a specific meningeal disease, it is usually ushered in by a headache of intolerable severity.

When the headache in any case is habitually very constant and severe, the disease is probably in the dura mater or periosteum; and this probability is much increased if the pain be local and augmented by firm, hard pressure upon the skull over the seat of the pain.

Disorders of Sleep.—There are two antagonistic

disorders of sleep, either of which may occur in cerebral syphilis, but which have only been present in a small proportion of the cases that I have seen. Insomnia is more apt to be troublesome in the prodromic than in the later stages, and is only of significance when combined with other more characteristic symptoms. A peculiar somnolence is of much more determinate import. This may occur in non-specific lepto-meningitis, and in states of altered brain nutrition from senile or other degenerations of the walls of the cerebral vessels, and is, therefore, not pathognomonic of cerebral syphilis, yet of all the single phenomena of the latter disease it is the most characteristic. Its absence is of no import in the theory of an individual case.

As I have seen it, it occurs in two forms: In the one variety the patient sits all day long or lies in bed in a state of semi-stupor, indifferent to everything, but capable of being aroused, answering questions slowly, imperfectly, and without complaint, but in an instant dropping off again into his quietude. In the other variety, the sufferer may still be able to work, but often falls asleep while at his tasks, and especially towards evening has an irresistible desire to slumber, which leads him to pass, it may be, half of his time in sleep. This state of partial sleep may precede that of the more continuous stupor, or may pass off when an attack of hemiplegia seems to divert the symptoms. The mental phenomena in the more severe cases of somnolency are peculiar. The patient can be aroused, indeed in many instances he exists in a state of torpor rather than of sleep; when stirred up he thinks with extreme slowness, and may appear to have a form of aphasia; yet, at intervals he may be endowed with a peculiar automatic activity, especially at night. Getting out of bed; wandering aimlessly and seemingly without knowledge of where he is, and unable to find his own bed; passing his excretions in a corner of the room, or in other similar place, not because he is unable to control his bladder and bowels, but because he believes that he is in a proper place for such act—he seems a restless automaton, rather than a man.

Apathy and indifference are the characteristics of this state, and yet the patient will sometimes show excessive irritability when aroused, and will at other periods complain bitterly of pain in his head, or will groan as though suffering severely in the midst of his stupor, at a time, too, when he is not able to recognize the seat of the pain. I have seen a man with a vacant apathetic face, almost complete aphasia, persistent heaviness and stupor, arouse himself when the stir in the ward told him that the attending physician was present, and come forward in a dazed, highly pathetic manner, by signs and broken utterance begging for something to relieve his head. Heubner speaks of cases in which the irritability was such that the patient fought vigorously when aroused; this I have not seen.

This somnolent condition may last many weeks. Dr. T. Buzzard (*Clinical Lectures on Dis. Nerv. Syst.*, London, 1882,) details the case of a man who, after a specific hemiplegia, lay silent and somnolent for a month, and yet finally recovered so completely as to win a rowing match on the Thames.

In its excessive development, syphilitic stupor puts on the symptoms of advanced brain softening, to which it is indeed often due. Of the two cases with fatal result of which I have notes, one at the autopsy was found to have symmetrical purulent breaking-down of the anterior cerebral lobes; the other, softening of the right frontal and temporal lobes due to the pressure of a gummatous tumor, and ending in a fatal apoplexy.

This close connection with cerebral softening explains the clinical fact that apoplectic hemorrhage is very apt to end the life in these cases of somnolent syphilis. Dr. Buzzard's case given above, and others which might be cited, prove, however, that a prolonged deep stupor in persons suffering from cerebral syphilis does not prove the existence of extensive brain softening, and is not incompatible with subsequent complete recovery. As an element of prognosis, it is of serious but not of fatal import.

Paralysis.—When it is remembered that a syphilitic exudation may appear at almost any position in the brain, that spots of encephalic softening are not a rare result of the infection, that syphilitic disease is a common cause of cerebral hemorrhage—it is plain that a specific palsy may be of any conceivable variety, and affect either the sensory, motor, or intellectual sphere. The mode of onset is as various as the character of the palsy. The attack may be instantaneous, sudden, or gradual. The gradual development of the syphilitic gumma would lead us, *à priori*, to expect an equally gradual development of the palsy; but experience shows that in a large proportion of the cases the palsy develops suddenly, with or without the occurrence of an apoplectic or epileptic fit. Under these circumstances it will be usually noted that the resulting palsy is incomplete; in rare instances it may be at its worst when the patient awakes from the apoplectic seizure, but mostly it progressively increases for a few hours, and then becomes stationary. These sudden partial palsies probably result from an intense congestion around the seat of disease, or from stoppage of the circulation in the same locality; but whatever their mechanism may be, it is important to distinguish them from palsies which are due to hemorrhage. I believe this can usually be done by noting the degree of paralysis.

A suddenly developed, *complete* hemiplegia, or other paralysis, may be considered as in all probability either hemorrhagic or produced by a thrombosis so large that the results will be disorganization of the brain substance, and a future no more hopeful than that of a clot. On the other hand, an *incomplete* palsy may be rationally believed to be due to pressure or other removable cause, and this belief is much strengthened by a gradual development. The bearing of these facts upon prognosis it is scarcely necessary to point out.

Although the gumme may develop at almost any point, they especially affect the base of the brain, and are prone to involve the nerves which issue from it. Morbid exudations, not tubercular nor syphilitic, are very rare in this region. Hence a rapidly but not abruptly appearing strabismus, ptosis, dilated pupil, or any paralytic eye symptom in the adult, is usually of syphilitic nature. Syphilitic facial palsy is not so frequent, whilst

paralyses of the nerve from rheumatic and other inflammation within its bony canal are very common. Paralysis of the facial may therefore be specific, but it is of no diagnostic value. Since syphilitic palsies about the head are in most instances due to pressure upon the nerve trunks, the electrical reactions of degeneration are present in the affected muscles.

There is one peculiarity about specific palsies which has already been alluded to as frequently present—namely, a temporary, transient, fugitive, varying character and seat. Thus an arm may be weak to-day, strong to-morrow, and the next day feeble again; or the recovered arm may retain its power, and a leg fail in its stead. These transient palsies are much more apt to involve large than small brain territories. The explanation of their largeness, fugitiveness, and incompleteness, is that they are not directly due to clots or other structural changes, but to congestions of the brain tissues in the neighborhood of gummatous exudations. It is easily seen why a squint will remain when the accompanying monoplegia disappears.

Motor palsies are more frequent than sensory affections in syphilis, but hemianæsthesia, localized anæsthetic tracts, indeed any form of sensory paralysis, may occur. Numbness, formications, all varieties of paræsthesia are frequently felt in the face, body, or extremities. Violent peripheral neuralgic pains are rare, and generally when present denote neuritis. Prof. Huguenin, however, reports (*Schwiez. Corr. Blat.*, 1875,) a case in which a severe trigeminal anæsthesia dolorosa had existed during life, as the only cerebral symptom, and death occurring from lung disease, a small gumma was found on the sella turcica pressing upon the Gasserian ganglion.

The special senses are liable to suffer from the invasion of their territories by cerebral syphilis, and the resulting palsies follow courses and have clinical histories parallel to those of the motor sphere. The onset may be sudden or gradual, the result temporary or permanent. Dr. Chas. Mauriac (*loc. cit.*, p. 31) reports a case in which the patient was frequently seized with sudden attacks of severe frontal pain and complete blindness, lasting from a quarter to half an hour; at other times the same patient had spells of aphasia lasting only for one or two minutes. In a case still under my care with unmistakable signs of cerebral syphilis, the man was suddenly and unaccountably seized with complete deafness, which after some days disappeared in the course of a few hours. Like other syphilitic palsies, therefore, paralyses of special senses may come on suddenly or gradually, and may occur paroxysmally.

Among the palsies of cerebral syphilis must be ranked aphasia. An examination of recorded cases shows that it is subject to vagaries and laws similar to those connected with other specific cerebral palsies. It is usually a symptom of advanced disease, but may certainly develop as one of the first evidences of cerebral syphilis.

Coming on after an apoplectic or epileptic fit, it may be complete or incomplete: owing to the smallness of the centre involved, and the ease with which its function is held in abeyance, a total loss of word thought is not so decisive as to the existence of cerebral hemorrhage as is a total

motor palsy. Like hemiplegia or monoplegia, specific aphasia is sometimes transitory and paroxysmal. Dr. Buzzard (*loc. cit.*, p. 81) records several such cases. Dr. Charles Mauriac (*Aphasie et Hémiplegie droite Syphilit.*, Paris, 1877,) details a very curious case in which a patient after long suffering from headache was seized by a sudden loss of power in the right hand and fingers, lasting about ten minutes only, but recurring many times a day. After this had continued for some alytic and were accompanied by loss of power of finding words, the height of the crises in the palsy and aphasia being simultaneously reached. For a whole month these attacks occurred five or six times a day, without other symptoms except headache, and then the patient became persistently paralytic and aphasic, but finally recovered.

To describe the different forms of specific aphasia and their mechanism of production, would be to enter upon a discussion of aphasia itself, a discussion out of place here. Suffice to say that every conceivable form of the disorder may be induced by syphilis.

Owing to the centres of speech being situated in the cortical portion of the brain, aphasia in cerebral syphilis is very frequently associated with epilepsy. Of course, right-sided palsy and aphasia are united in syphilitic as in other disorders. If, however, the statistics given by M. Tanowsky (*L'Aphasie Syphilitique*) be reliable, syphilitic aphasia is associated with left-sided hemiplegia in a most extraordinarily large proportion. Thus in 53 cases collected by Mr. Tanowsky, 18 times was there right-sided hemiplegia, and 14 times left-sided hemiplegia, the other cases being not at all hemiplegic. Judging from the autopsy on a case reported in Mauriac's brochure, this concurrence of left-sided paralysis and aphasia depends partly upon the great frequency of multiple brain lesions in syphilis, and partly upon the habitual involvement of large territories of the gray matter secondarily to diseased membrane. An important practical deduction is that the conjoint existence of left hemiplegia, and aphasia is almost diagnostic of cerebral syphilis.

EDITORIAL DEPARTMENT.

PERISCOPE.

An Operation for Hallux Valgus.

Dr. Arthur E. Barker thus writes in the *Lancet*, April 12, 1884:

The deformity hallux valgus is one for which it will probably be admitted a cutting operation is rarely demanded. In the first place, the condition being one due in almost every case to ill-fitting boots, which force the great toe out of the line of its metatarsal bone into strong abduction, it is possible by proper attention to the shoeing of the patient, by methodical manipulation of the faulty toe, and by placing pads between the latter and its neighbors, to bring it in most cases into a fairly comfortable position once more. Still every surgeon must meet from time to time with cases of this deformity which baffle all ordinary endeavors to bring about even a tolerable state of things, and where the great toe lying crosswise, either under or over its fellow, gives rise to such inconvenience, if not actual suffering, as practically to cripple the individual so affected. Under these circumstances patients are willing to undergo any treatment in order to be relieved, and will even urge the surgeon to amputate the offending member, which is interfering with all comfort in progression.

The following case will illustrate remarkably well the evils of this condition, and will serve also for the demonstration of a simple operation which was practiced with perfect success for its cure.

X—, aged nineteen, was brought to me as an out-patient in November, 1882. He complained much of being crippled by the deformity of his toes. I found both feet to present the deformity in question acutely, but most marked on the right

side, where the nail of the great toe lay under its fellow, its matrix being in a state of suppuration from the pressure and irritation, and the parts exquisitely tender. Various measures had been tried before I saw the patient to relieve him, attention being particularly directed to the inflamed matrix and ingrown nail. I did not anticipate much difficulty in relieving the patient, and treated him by cutting out the imbedded portion of nail and dressing the ulcerating surfaces with antiseptic materials placed thickly between the toes. This, however, proved of no permanent benefit to the patient, for on trying to walk the great toe always reassumed its vicious position under that next it, and the ulceration commenced as before. Finally, after a long treatment, the patient's father and a friend came to me and urged me to take stronger measures, and if necessary remove the toe, as the youth had been thrown out of work and was unable to take any exercise for a long time. I was of course averse to amputation of the member, though it was only an encumbrance, and began to review for the students present all the measures which have from time to time been resorted to for improving the deformity. In doing so I was dwelling on the question of excision of the metatarsal phalangeal joint recommended by some, when one of our students, Mr. C. Hoar, asked me if the condition was ever relieved by osteotomy of the metatarsal bone, and straightening of the toe thus without interfering with the joint at all, as he had often seen me operate for genu valgum. I told him that I did not think it had been done hitherto, but that the idea seemed such a good one that we should put it in practice in this case at once. The patient and his father accepting the proposal to do so with great readiness, I performed the following simple operation with the strictest Listerian antiseptic

precautions. Having first made an incision through the soft parts about an inch long, on the inner aspect of the metatarsal bone, above its head, I cut out with a chisel a small wedge-shaped piece of bone from the shaft just above the head, the base of the wedge being on the inner surface of the bone, and the apex at a point nearly through to the other side. Then, by forcibly abducting the great toe, I snapped the uncut remainder of the metatarsal bone, and brought the whole member into a straight line. In this position it was easily retained by a narrow splint along the inner border of the foot. The wound was dressed antiseptically, and the patient was allowed to go home at once. But little remains to be said about the case. The wound was left undisturbed for ten days, and was then found practically healed and without suppuration. The splint was, however, left on for a few days longer, after which, as the bone had united in its straight position, the patient was allowed to return to work, which he was soon engaged in as actively as ever. I have seen him several times since at intervals (yesterday, Feb. 18th, 1884, for the last time, *i. e.*, over two years after operation), and the toe is almost quite straight, although a little bent by a bad-fitting boot since worn. He is quite relieved of all the troubles incidental to this deformity.

It will be observed from the above short description, that this simple operation is almost the same as that we are in the habit of performing for genu valgum. Here, however, I thought it better to remove a small wedge of bone, instead of simply dividing the part transversely, as in the case of the knee. I imagined there might otherwise be some difficulty in bringing the parts into position, remembering the short leverage of the toe as compared with that of the tibia. The course of the healing process was as completely satisfactory as those osteotomies usually are under the antiseptic treatment of wounds. It was without suppuration, pain, or fever. The toe has been a little stiff since, as might be expected; but the patient does not wish any forcible flexion of it, as the stiffness gives him no inconvenience.

I have purposely avoided going into minute details of this operation. Its principles and practice must be perfectly clear to any one familiar with osteotomy for genu valgum, now so commonly practiced. It is quite simple and free from risk, if performed with strict antiseptic precautions: and though not often called for, still I cannot help thinking that there is a useful place for it in surgery.

This little operation may have been done before, but I cannot find any record of such a procedure. If it be original in this case, the merit of the suggestion lies with one of our students at University College Hospital.

The German Cholera Commission.

The *Brit. Med. Jour.*, April 12, 1884, furnishes us the following in reference to Dr. Koch's latest report:

The "Seventh Report of the German Cholera Commission," dated Calcutta, March 4, recently published in Berlin, is a document of no small importance, as it supplies evidence on the ques-

tion of the mode of origin of epidemics, and the method of propagation.

The evidence distinctly supports the theory that cholera is spread by a water-borne contagion. The report deals chiefly with the occurrence of small local epidemics of cholera in the neighborhood of "tanks." These "tanks," which are scattered over the whole country in vast numbers, are, in reality, small ponds, often in marshy ground, surrounded by a few huts. The inhabitants use the water of the tank for every purpose, washing, bathing, and drinking, and latrines of a very primitive design are frequently erected on the banks and drain into the "tank." The water of these tanks is, of course, under these circumstances, highly charged with foul organic matter; and it is said to be within the experience of all who have seen much of cholera, that local epidemics occur with considerable frequency in the neighborhood of these tanks. The Sanitary Commissioner of the government, having been applied to by Dr. Koch, was able in the end of February to direct his attention to Saheb Bagan, a suburb of Calcutta, where such a local epidemic was in progress; it was entirely limited to the inhabitants, about one hundred in number, of huts built around the pond. Seventeen deaths from cholera occurred among these hundred persons, though during the same period, in the other parts of the police district in which the tank is situated, no cases of cholera were reported. It was ascertained that the water of the "tank" had served the inhabitants for purposes of bathing, washing, and drinking, and that the linen of the first fatal case of cholera, smirched with the dejections, was washed in this "tank." Samples of water were taken from different parts of the pond and examined by the method of cultivation on gelatine. It was found that the first samples were rather rich in the cholera-bacillus, whereas of those obtained at a later period, and near the termination of the epidemic, the characteristic bacillus was only found, in very small numbers, in one sample taken from a very dirty part of the pond. This was the only instance which could be examined, but Dr. Koch contends that it affords strong evidence of one of the ways by which the poison of cholera finds its way into the human body.

The examination of cholera-dejections, and of the bodies of persons who had died of cholera, had been continued by the Commission; and the results obtained had confirmed, without extending or otherwise modifying, those previously published.

Experiments have been made by the Commission to ascertain the influence of disinfectants, such as corrosive sublimate and carbolic acid, on the growth of the bacillus in culture fluids, and also the results of cultivation in an atmosphere of carbonic acid gas, and in a closed chamber.

No definite results have as yet been obtained with regard to the question of the conditions under which the bacillus can retain its vitality. It does not seem to be able to preserve its vitality when dried, but if kept moist it can be preserved for a long time. In liquids it can maintain its vitality for several weeks, and Dr. Koch thinks that all the evidence tends to show that the infection can only be introduced into the human body in a moist state.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

AN OBSTETRIC CASE

(Price, \$15.00),

OR

AN ELECTRIC BATTERY

(Price, \$25.00),

AS PREMIUMS.

Any subscriber to the REPORTER who will send us before the 1st of July the names of *three* new subscribers with their yearly subscriptions (\$15) or *five* new subscribers with \$25.00, will receive, for the three, an Obstetric Case complete, and for the five, an Electric Medical Battery complete. They are new, of the best make, and of guaranteed excellence. The new subscribers will receive the REPORTER *free* from the date of the remittance until July 1st next.

Address DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA, PA.

THE NEW FEBRIFUGE—KAIRIN.

The reports of the remarkable antipyretic effect of kairin continue to augment. Most observers seem to agree that it is best to begin in adults with a dose of about $12\frac{1}{2}$ grains, to repeat this two hours later, then to administer 9 grains every two to three hours, until the desired effect—decrease of temperature—has been obtained, when a smaller dose, about 5 grains, employed every three hours, usually suffices to keep down the temperature. But at the least indication of the temperature falling below normal, the remedy must either be omitted or given in small doses and at very long intervals, say 3 grains every twelve hours. Should, however, the temperature nevertheless again ascend, the same course as described must be gone through anew.

At a recent meeting of the society for gynecology in Leipsic (*Allgen. Med. Centr. Zeit.*, 1884, 1), Dr. Hennig reported on the effect of kairin in parturient women and in children. He had employed the new drug in three cases of women in childbirth, dangerously ill. Patient had been confined to bed for six weeks. She suffered, aside from the puerperal fever, from a bed-sore of the size of a child's hand, and penetrating to the periosteum of the sacrum. The second patient became attacked in the second week of childbed by peri- and para-metritis dextra, perforating later into the rectum; chronic pneumonia also became added; there was inclination to tetanus; and frequent vomiting, besides anæmia in a high degree, were other complicating phenomena. The third evinced typhoid symptoms and diarrhœa lasting three days. The children were suffering, one from scarlatina; one from diphtheria, with high fever; and one with laryngeal stenosis, necessitating tracheotomy.

In all these five cases the kairin was administered after all the well-known and usually considered effective febrifuges (quinine, salicylate of sodium, application of cold, and especially baths), had proven themselves incapable of reducing the fever from its height (41.6° to 42.4° C.). The decrease of temperature promptly took place in all five cases, and amounted in the adults to 2°

C., and in the children (æ. 2 to 3) 1° to 1.8° C.

The antipyretic effect of kairin has been demonstrated not only to come up to the expectations of its discoverer, but also to surpass them; for all these five persons, in whom the prognoses had been so grave as to induce the physicians attending them, ere Hennig saw them, to consider them beyond all hope, and still they were free from fever, the operated boy after recovering from a grave form of bronchitis. Intense (black-green) discoloration of the kairin urine was observed only in two of the women; the third reported as the next visible effect of the kairin, cessation of all pains.

NEWS AND MISCELLANY.

Pennsylvania State Medical Society.

(Concluded from page 639.)

Then followed the Address in Obstetrics, by Dr. Jacob Price, of West Chester, which began with a reference to the remarkable rapidity with which the present advanced condition of obstetrics has been reached. "A hundred years ago it was not recognized in the curriculum of the medical college. The first medical school in this country, established in Philadelphia in 1765, contained no provision for the study of obstetrics. After some time it was attached to the chair of anatomy, and thereby fortunately came into the hands of Dr. Wm. Shippen, who by his previous careful training under Smellie and Wm. Hunter, was peculiarly fitted to teach this new branch of medical science and extend its interest. Aided by Drs. Bond, Duffield, and James, Dr. Shippen succeeded in establishing a lying-in hospital, with clinical lectures upon midwifery in connection with it."

"It was not, however, until 1810 that the chair of obstetrics in the University of Pennsylvania was separated from that of anatomy; and even at this date the ban of the profession rested so heavily upon it that not until 1813 was attendance upon the obstetrical course made a requisite for graduation."

Reference is made to the advanced condition of obstetrics and gynecology, as shown by the translators of the works of Oribasius and Cælius, presented by Prof. Maughs, of St. Louis, at the meeting of the American Medical Association in 1883. The pernicious vomiting of pregnancy is a trouble to which Dr. Price seems to have given special attention; and as his points are somewhat new, and the results in treatment most satisfactory, we give his discussion of it in full.

Perhaps the first trouble for which the pregnant female seeks the counsel of her medical adviser is the sick stomach that usually attends the early months of utero-gestation. This, by the laity and by too many physicians, is looked upon as a trifling affair, and receives but little attention. Fortunately in the vast majority of cases it is not

serious, and yields to remedies addressed to the stomach itself. But sometimes all such treatment fails to give relief—the symptoms grow steadily worse. It is no longer a morning sickness. Nearly all food is rejected—emaciation and loss of strength steadily progress. The nervous symptoms deepen—evidences of inanition become pressing. The routine practice of the books fails to stem the downward tendency. The induction of premature labor, with all its dangers, is taught and accepted as a necessity to avert death from inanition. Early in my practice two such cases came under my notice, one of them in my own practice. Both proved fatal—my own case after the induction of abortion. The study of the subject induced by these unfortunate cases, established the fact that not one of the systematic works upon obstetrics to which I could gain access, gave any well-defined views as to the pathology of this most serious malady, or any treatment except palliative medication, evidently of a routine character, all of which, in these grave and protracted cases, experience proved totally unreliable. Step by step I reached the conclusion that in these unmanageable cases of vomiting during pregnancy—"pernicious vomiting," as it has recently been designated—there was present congestion or inflammation of the uterine cervix. In no case did examination fail to disclose the presence of local disease of this character, and treatment based upon this view proved eminently satisfactory.

In a paper upon the subject which I had the honor to read at the meeting of this society in Lancaster, in May, 1881, I embodied these conclusions in regard to the pathological condition present in this disease—detailed the steps of treatment I had found prompt in affording relief, and reported several illustrative cases. My paper was severely attacked, upon theoretical grounds alone, but I had the satisfaction of finding it warmly defended and thoroughly sustained by the practical men present, those whose daily work led them to the bedside of the sick and suffering.

Since 1881 five cases of "pernicious vomiting" have come under my own notice, and several more under the care of physicians with whom I have corresponded, and in no one has treatment, local and general, based upon the foregoing pathological views, failed to afford relief. I will give briefly three cases of my own, and four in the practice of other physicians.

The first was in one of the patients named in my former paper. A subsequent pregnancy was attended by the same extreme symptoms. Remembering the relief in her former trouble, she sought treatment before the emaciation and nervous prostration had made much progress. She soon recovered. I will here state the points of treatment: Relief of constipation, if present, by effervescing saline; rest in bed; emollient vaginal injections, and applications at intervals of three days of a solution of iodine, crystalized carbolic acid and tannin, each two drachms, dissolved by heat in an ounce of pure glycerine: in some cases I add morphia and atropia; a vaginal tampon of absorbent cotton saturated with pure glycerine, and followed by a dry one, is placed at each treatment. Usually not more than three or four of these applications are required.

The second case was the wife of a prominent physician of this city. I will let her husband give the case in his own words:

"My wife was operated upon for lacerated cervix, by Dr. A. H. Smith, in April, 1883. Her second pregnancy began in June following. In July extreme and incessant vomiting came on. All ordinary, in fact all known remedies, were tried, but nothing proved of any avail. Toward the latter part of August you took charge of the case, at which time I considered her condition very critical, and had grave doubts of the possibility of carrying her through the gestation safely. The speculum revealed a generally congested and livid appearance of the whole uterine neck, with leucorrhœal discharge, coming evidently from the cavity of the cervix. A careful application of your modified Battey's solution was made to the os and neck of the uterus. Within twelve hours decided relief was manifested. These applications were repeated three times a week for three weeks, by which time her condition was so much improved that they were discontinued, except at intervals of some weeks, when there was slight return of sickness. Labor set in March 23. The first stage slow; second very rapid; recovery satisfactory; but recent examination discloses at least a partial reproduction of the laceration."

In commenting upon this case, I may say that the partial return of sickness was no doubt due to the too early discontinuance of the regular twice-weekly application. A private letter from the patient expressed in most grateful terms the prompt and complete relief she derived from the treatment.

My third case was also the wife of a physician. He wrote me that his wife, then in the fourth month of gestation, was extremely ill from uncontrollable vomiting. That in three former pregnancies she had suffered from sickness that resisted the usual remedies, but she was so much more ill now, that with his former experience of the inefficiency of medication he feared for her life, and was disposed to think abortion would soon be an absolute necessity. I suggested the treatment already described.

In three weeks he informed me that his wife had been entirely relieved by the rest and injections alone, and that she was attending to her household duties with entire comfort. I saw her three months later, quite well, and enthusiastic over the relief she had received from the simple yet most efficient treatment.

Dr. P. informed me that some weeks before writing me, in view of the necessity for removing the contents of the uterus, he had consulted a prominent teacher in obstetrics, and had received no suggestions beyond the routine medication of the books, all of which he had tried in this and her previous pregnancies without any good result. I mention this to illustrate how little thought and study this most serious and at times dangerous malady has received at the hands of those to whom we look as authority in all that pertains to obstetrics.

My neighbor, Dr. C. E. Woodward, has given me the notes of two cases, one aged 30—the fourth pregnancy in five years. He saw her first April 14, 1883, two months pregnant. There was constant nausea and vomiting, great anemia, and nervous depression amounting to melancholia.

She had profuse leucorrhœa and painful micturition. A vaginal examination disclosed a lacerated cervix. The os uteri was swollen, red, and sensitive to the touch, and with a profuse acrid discharge. I painted the os and cervix freely with a mixture of tr. of iodine, glycerine, and carbolic acid, morphia and atropia, and left a vaginal pad of cotton saturated with glycerine. These applications were made at intervals of four days for about a month, by which time the discharge had ceased, the evidence of congestion and inflammation of the os and cervix had passed away, and the sick stomach was entirely relieved. Two months later the complaint returned, and with it the evidence of local disease. A few applications removed the latter, and again the vomiting and other distressing symptoms disappeared.

Dr. Woodward's second case, a primipara. The vomiting came on early and resisted all medication. By the third month she was very much emaciated, and the prostration extreme. A vaginal examination disclosed a swollen and congested cervix, tender to the touch, which seemed immediately to increase the nausea. Applications were made as in the former case. A favorable impression was apparent after the first application, and by the fifth the relief was complete. There was no medication after the local treatment was begun.

Dr. Massey, also of West Chester, reports a case in which, after three months of sick stomach, resisting usual remedies, the use of warm vaginal injections, painting the cervix with comp. tr. of iodine and glycerine, and the vaginal pledget of cotton, saturated with pure glycerine, was followed by complete relief. In this case there was retroflexion, which was corrected by one of Smith's pessaries, the use of which was continued until the seventh month of gestation.

Dr. Boardman Reed, of Atlantic City, N. J., has kindly sent me the following case, which I give in his own words: "A lady pregnant for the third time complained of almost unremitting nausea and vomiting. She said that in her previous pregnancies she had suffered for months in a similar manner, and that medicines did her no good. I tried various remedies for her without avail, until about the end of the second month, when her sufferings were so great that she threatened to have an abortion produced. Emboldened by the experience of Dr. Price, as recorded in his paper on this subject read before the Medical Society of the State of Pennsylvania in 1881, I applied the comp. tr. iodine freely to the os and cervix uteri, which upon examination was found to be congested and tender. The relief from this distressing sickness was immediate and decided. A second application, made a week later, so far cured the trouble that the patient made very little complaint thereafter. No pain or bleeding followed the application."

Gentlemen, my apology for referring so much in detail to this subject, "the pernicious vomiting of pregnancy," is to be found in the conviction that has been forced upon me after long and careful study of it—that no disease so important in its bearing upon the comfort and safety of the patient has been so little studied, is so unsettled in its pathology, and the treatment of which has been so unsatisfactory. That it is often serious all must

admit. Guéniot (as quoted by Playfair) collected 118 cases of the graver form of the disease, out of which 46 died, and out of 72 that recovered, in 42 the symptoms ceased only when abortion either spontaneous or induced had occurred. That it has not received from systematic writers on obstetrics the study its importance demands, is very evident. A few paragraphs, reproducing a routine treatment, that repeated experience has shown inefficient, is all the space devoted to it by some claiming to be comprehensive.

Playfair alone, of all I have been able to consult, recognizes fully the gravity of the class of cases I have been discussing, and admits the unsatisfactory character of our knowledge, both of its pathology and treatment. He, as well as Leishman and Lusk, speaks of inflammation as a possible cause in some cases, but lays no stress whatever upon this view. I. Henry Bennett is the only author I have found who distinctly refers to "inflammatory ulceration of the cervix uteri" as a possible cause of obstinate vomiting in pregnancy.

A recent French writer, Dr. Suturgin, in "*Archives de Tocologie*," after elaborate study, draws the following conclusions: "That the symptoms are very analogous to those of inanition, which explains the decreased urinary secretion, and the presence of albumen and cylinders in the urine. That death takes place, either from exhaustion or from intercurrent puerperal disease or from diseases that have no direct relation to pregnancy, that the nature of the affection is still unknown, and finally, if therapeutic means fail (and none are pointed out) premature delivery must be resorted to."

Dr. Grailly Hewitt advanced the theory that the disease in question depends upon flexion of the uterus, producing irritation of the nerves at the seat of flexion and consequent sympathetic vomiting, but it received little favor when discussed by the London Obstetrical Society. My own observation disproves it entirely. I have met with several cases of flexion of uterus during the early months of pregnancy without serious sickness, and in no case of "pernicious vomiting" have I found it present. The generally received explanation is that the vomiting is due to the stretching and consequent irritation of the uterine nerves by the growing ovum. This is probably true so far as the slight morning sickness is concerned, but is totally inadequate to explain the grave form of the disease.

Horwitz, of St. Petersburg, has given, very recently, an elaborate paper upon the uncontrollable vomiting of pregnancy. In common with Guéniot, who adopts the term, "*Vomitus Gravidorum Perniciosus*," he draws the distinction sharply between this form of disease and the morning sickness of the early weeks of pregnancy. The former begins most frequently between the tenth and eleventh weeks. He discusses the various explanatory theories that have been proposed, but declares that none are satisfactory. The prognosis, he thinks, depends much upon the epoch of pregnancy in which the trouble appears. The nearer to the beginning the worse the prognosis, especially in the case of primiparæ. He quotes Joulin as giving the mortality at 44 per cent. As to treatment, he offers nothing new. In danger-

ous cases, in which life is threatened, artificial abortion becomes a necessity.

In concluding this subject, I am glad not to leave you with the unsettled and discouraging views which these distinguished writers have reached, but to state distinctly as the result of careful study of the disease, now extending over a period of many years, that the "pernicious vomiting of pregnancy" is dependent in a vast majority of cases upon congestion and inflammation of the lower segment of the uterus; and I here wish to assert so emphatically as to arrest the attention of every physician now present, that I know of no disease of equal gravity that so surely yields to established rules of treatment as this one does to treatment based upon the view of a congestive or inflammatory causation, viz., rest in bed, emollient and mildly astringent vaginal injections, the tepid sitz bath, and especially, in extreme cases, the topical application of Battey's or a similar sedative lotion to the uterine cervix. I am sure that no one who carefully and intelligently carries out this plan of treatment will fail to bring relief in the most obstinate case.

In discussing the treatment of cases of abortion, the address takes strong ground against immediate instrumental interference to remove the secundines, and reprobates the practice of some of the younger writers, who would make every miscarriage an excuse for scooping out the cavity of the uterus. "Such active interference is uncalled for and mischievous in a vast majority of these cases." The use of vaginal or cervical tampon (disinfected) will in most cases be followed by the almost painless and usually safe expulsion of all the contents of the uterus, and thus the dangerous element of traumaticism avoided. "Yet when operative means really become necessary," Dr. Price says, "there is no question that the smooth wire curette of Thomas, or the larger one described by Mundé, is the safest instrument that can be used. It is far less painful than the finger, more efficient, and if used carefully is less liable to produce injury."

The potency of uterine flexion in causing abortion in the third month is referred to, and in the writer's opinion is so frequent in its operation, that a vaginal examination during the second month of the gestation is advisable.

The address severely reprobates any manipulation of the os uteri during the first stage of labor, and especially any attempt at its rapid and forcible dilation. "More especially is this meddlesome and mischievous manipulation of the cervix in this stage of labor to be deprecated, when we have in the use of morphia, hydrate of chloral, and other anæsthetics, such safe and efficient means of overcoming the painful delay that so frequently attends it."

To the care of the perineum, during its extreme distention as the head descends, so as to prevent laceration at the moment of delivery, the address devotes considerable attention. The danger of leaving it entirely alone, as taught by some, is pointed out. The plans proposed by Playfair and Goodell, to relax the perineal tissues, while approved as accessory measures, are claimed to be insufficient. The point enforced in the address is that the descent of the head must be prevented by firm pressure directly upon it, until the peri-

neal tissues have had time to yield slowly, yet sufficiently, to allow the head to pass safely. To carry out the points made by Professors Playfair and Goodell, viz: "to relax the tissues of the perineum," and at the same time to assist in restraining the too rapid descent of the head, Dr. Price has recently used a towel four feet long, folded lengthwise to a width of six inches, passed in front of the pubes and over the trochanters, the free end secured by two strong safety pins, over a firm pad resting against the os-coccygis and the anal orifice. The effect of this is to crowd the surrounding tissues in the direction of the vulvar outlet, securing all the relaxation that is possible, at the same time keeping the head pressed towards the pubic arch.

The action of this pad and band is pleasant to the patient and effectually protects the coccyx from injury, which, as is well known, is often the cause of that most serious malady, coccydynia. At the moment of greatest distention, the action of the band should be aided with the left hand of the accoucheur, while the other resists the too rapid advance of the head by direct and firm pressure.

In every case the perineum should be inspected, and if any rupture of its proper tissues has occurred, the surface should be dusted with iodoform and closed by the proper suture.

The danger attending post-partum hemorrhage and recent teaching as to the best means of meeting it, are discussed at some length. "The chief point to be kept in view is to secure a firm tonic contraction of an empty uterus." The administration of a full dose of ergot just at the completion of the second stage of labor, is a matter of routine by many of our best obstetricians. The placenta should be immediately expelled by the Credé method—*using both hands*. The compression is to be continued until the action of the ergot is well established. If this is done no coagula form, there is little subsequent hemorrhage. The impression of the ergot should be kept up for twelve hours, and if a tendency to relaxation exists, for a longer period. The involution of the uterus is, by this treatment, advanced, and the risk of the septicæmia greatly reduced. * * * *

"Occasionally, however, in spite of every precaution, we fail to get contraction, and blood pours out in torrents. The uterus remains a limp, flabby bag. These cases are fraught with the greatest peril, and unless met with skill and promptitude will surely be lost." * * * * The one great point to be accomplished, viz., uterine contraction, must be kept distinctly in view; mere styptics will be unavailing. Profs. Wallace and Penrose, of this city, rely with confidence upon a sponge or soft cloth soaked in vinegar. The former says the effect of the vinegar is magical. The flabby uterine muscle instantly responds. The organ assumes a gizzard-like feel, shrinking down upon and compressing the hand. In the vast majority of cases the hemorrhage ceases instantly.

Dr. Albert H. Smith, in common with a large number of practitioners, relies upon injection into the uterus of a stream of water at a temperature of about 115° F. Dr. E. Wilson's preference is for a lump of ice passed quickly into the uterus, and upon this I have for many years relied, without failure in any case. * * * * Dr. Barnes

introduced and extolled in the most decided manner, the intra-uterine injection of solution of persulphate of iron in the proportion of one to three of water; but in the prolonged and very able discussion of his paper in the London Obstetrical Society, the dangers that attend this practice were fully established, and its use is not now supported. Swabbing the uterine surface with the iron is enthusiastically recommended by Engelman and others.

Placenta-prævia claims considerable attention in the address. "Shall the pregnancy be allowed to continue?" is a question that in every case has to be met at the onset. In the discussion in the Obstetrical Society of London, of a very able paper by Dr. Greenhalgh, advising the immediate induction of labor in all cases of placenta prævia, all the eminent gentlemen that participated, although differing upon details, agreed as to the inadvisability of allowing the gestation to go on after the diagnosis had been positively made.

The plan of management so ably advocated by Dr. Davis, of Wilkesbarre, in the address on Obstetrics for 1876, is approved, but is not successful in all cases. "Sometimes there is failure to get the forceps applied, the bleeding goes on, and version must be resorted to at once, or the bleeding is profuse and obstinate before dilatation allows of the procedures of Dr. Davis. Our old friend, the tampon, must be called in, or better, the colpeurenteur of Braun, filled with water tightly enough to distend the vagina and stop the flow, or better still, the carbolized sponge tent of large size passed well up the cervix. Dr. Jungbluth, of Aix la Chapelle, at Friedburg meeting of the German Gynecological Society, strongly advocates this treatment, and gives minute directions for the preparation of these tents, and the manner of using them. He reports six cases; all the mothers were saved, and only one child lost. Hofmeier and Behm, of Berlin, condemn the use of the tampon in all cases, and strongly urge premature combined version and slow extraction, with certainly brilliant results so far as the mother is concerned—one death in eighty-two cases—but their mortality with the children is frightful, being over 70 per cent.

After careful study of the whole subject of placenta prævia one cannot avoid the conclusion so well stated by Lusk, "that the result depends in a large measure upon the personal qualities of the physician in charge. A self-possessed man, cool, resolute, and with clear ideas of the anatomical conditions to be dealt with, will, if summoned in season, deprive even placenta prævia of a good share of its terrors."

The pathology and treatment of puerperal convulsions receives careful attention in the address, and the diversity of opinion that exists is deplored. Though usually associated with albuminuria, the fact is well established that the condition is not always present. "The generally received explanation is that these attacks arise from overstimulation, reflex in its origin, of the vaso-motor and convulsive centres, and this may occur independently of uræmia, although this condition vastly increases its liability." In treatment the deleterious influence of mental excitement, exposure to cold, and indigestion, are to be kept in mind. When an attack threatens, full doses of

bromides, of hydrate of chloral, and morphia (the latter hypodermically), are indicated when the action of the kidneys is deficient; the muriate of pilocarpine (hypodermically), aided by hot foot-baths to bring on diaphoresis, are very beneficial. But perhaps the most efficient of all remedies, at this stage, is the free abstraction of blood. No other means can be so safely relied upon to lower arterial tension, diminish irritation of the vasomotor and convulsive centres, and restore to the kidneys their normal functions. Spiegelburg claims that these three indications are most completely filled by venesection.

Dr. Price traces the causes that brought this fine "therapeutic measure" into disrepute, and earnestly pleads for its proper use.

Puerperal fever is the last subject discussed, and from its great extent* this discussion is necessarily limited. The difference in views of Profs. Thomas and Barker, as brought out in a recent discussion in the New York Academy of Medicine, is referred to. The writer concludes the subject by a brief statement of the pathology, etiology, prophylaxis and treatment from the Vienna standpoint, as recently given by Prof. W. M. Jaggard, of Chicago, in the *Medical News*, of this city.

Dr. Price in conclusion said, "I wish to congratulate you upon the progress that marks the history of Modern Obstetrics. The greatly increased skill in action and precision in results is most encouraging. Time will not permit of details, but I will name the use of anæsthetics, the better appreciation of the action of opium, ergot, chloral, pilocarpine, and of hot and cold applications, and consequently their more judicious and efficient use in practice. And lastly the general use of antiseptics, by which the results in operations have been vastly improved and the most formidable disease of the parturient condition shorn of much of its danger. To the younger members let me say that no branch of our science is more worthy of or requires higher culture than this.

"The difficulties and dangers to be met are not only equal to those in any other part of surgery or practice—but they are likely to be sprung upon you without time for special preparation. In most of the formidable operations of surgery you can look about you and prepare carefully for the work—but in obstetrics, a convulsion, a frightful post-partum hemorrhage, or a ruptured uterus, may confront you most unexpectedly.

"To the young men in our ranks I earnestly appeal, to make yourselves, in every way, worthy of the confidence of the other sex—for it is the highest tribute that can be paid to your professional culture and purity of character, for an intelligent and pure-minded woman, to seek your care in the perils of child-birth or in the diseases peculiar to her sex.

"In making this appeal to you, specially, I intend no discourtesy to those excellent women who, despite all obstacles, have trained themselves for good work in the profession, and whom we have, at last, been sufficiently just to admit to full membership. I make it simply because of

my conviction that in all the future, as it has been in the past, the chief burden of professional work must come upon our sex. The place of women in medicine, as in all public life, is exceptional, and must ever be limited. And in speaking thus I have no wish to open up the much abused and perhaps silly question of woman's rights. She is as ourselves, a human being, having the same impulses, equal talents, and confessedly greater quickness of discernment, and she should certainly have the same *right* as ourselves, to do anything that is respectable and proper. And it is mean and tyrannical in man, the stronger, to place obstacles in the way of any individual woman, who—impelled by God-given talents, or perhaps by necessity put upon her by the indolence or incapacity of a father, or husband, or brothers—seeks the honors and emoluments of public life. Yet such must ever be exceptional. God has not left it for man, or woman either, to arrange the respective duties of the sexes. He has stamped upon woman, functions which involve duties that will always limit her public life. Exceptional women may be successful merchants, doctors, lawyers, or even captains, but through all time the mass will continue to be wives, and mothers, and sisters, and find their highest duty, as well as purest happiness, in keeping up in all its sacredness and purity, the true home—that institution upon which, more than upon churches, and constitutions, and armies, depends the perpetuity of virtue, of liberty, and of independence."

"OBSTETRICAL FORCEPS JOINED AT THE JUNCTION OF THE BLADES AND SHANKS,"

was the title of a paper by Dr. J. A. McFerran, of Philadelphia, who said:

The much ado about individual skill in the use of the obstetrical forceps, the confusing descriptions of complicated manœuvres necessary to their proper handling, the solemn warnings of celebrated teachers to the young and inexperienced, are reflections upon the intelligence of the majority of the profession, or a confession that it is an instrument which should be banished from use.

Of necessity, there can be but few experts; every practitioner should, therefore, be qualified to use the instrument. To me, it seems an incomprehensible thing that any one taught as they must be in our colleges, could be incompetent to use the forceps properly, and yet be qualified to practice safely the more recondite duties of their calling.

In no branch of our profession is prompt, decisive, and intelligent interference called for oftener than at the bedside of a woman in labor; and there is no instrument at the bedside so efficient as the forceps, and none in the whole domain of surgery should be better understood.

After recounting what he considered to be the chief objections to all the forceps in ordinary use, the speaker said: "I designed a pair of forceps in the fall of 1877, joined at the junction of the blades and shanks, upon which I read a paper before the Philadelphia County Medical Society, that was published in the *MEDICAL AND SURGICAL*

* Dr. Price, in speaking of vaginal irrigation in cases of puerperal fever referred to a bed pan devised by Dr. Hanks, of N. Y., as greatly facilitating the operation. It is well made, at a very moderate price, by George Marston, 406 East 20th street, New York.

REPORTER of December 1 and 8 of the same year. These forceps I bring before the Society after having fully tested them on several occasions after the failure to deliver with other forceps, and always with perfect and quick success; and I can now, with a confidence such as experience alone can give, urge upon the profession a trial of this instrument. Once the forceps applied to the head, it is left free to deflect, flex, or extend. The line of traction is transferred from the junction of the head and neck to the joint of the instrument. By making the handles a lever, and one hand the fulcrum, placed close to the vulva, the head can be flexed and swept down in the axis of the pelvis. Even when traction is made from the extremity of the handles, the joint leaves the head free to deflect and pass an obstruction with the greatest possible ease. A chain will pass through a long and tortuous tube, when the length of the links does not exceed the distance between the curves, and it is upon this principle that the instrument acts when traction is made. Positions may be corrected, doing away with the use of the lever and a formidable array of instruments, avoiding dangerous delays and long-continued pressure. To illustrate, I have selected the sacro-pubic position. The head is somewhat extended and caught at the superior strait, the forehead resting on the promontory of the sacrum and the occiput on the pubic bone. Of course, the proper thing to do would be, if we could, to turn the forehead to the right and convert the third into a first position. But, if we suppose the head forced down between the two points, we may not be able to do so; only experts, after much trouble, could do so. With the ordinary forceps, as generally used, the head would be forced more and more between the opposing points of the strait. But with the jointed instrument the difficulty could be easily overcome, by producing greater flexion. Operating through the joint upon the vertex, it would be tilted back towards the hollow of the sacrum, thus liberating the head and facilitating its descent. In other positions the diameters can almost be made to coincide, by operating through the joint. In all cases we should endeavor to keep the head flexed, in order that it may avoid obstructions and the more easily rotate or be rotated in the pelvis. The nearer the posterior fontanelle can be kept to the centre of the pelvis, the easier will the labor be; with the jointed instrument this can be done without the manifestation of any great amount of skill by the operator. I ask you to remember that the jointed instrument has all the advantages of the ordinary forceps, as a tractor, as a lever, and in the independent application of the blades, while the disadvantages are dropped by simply placing a joint so that the motions of the fetal head shall not be interfered with."

Then came Dr. Mary Stinson's paper on the "Work of Women Physicians in Asia," which we publish elsewhere, after which the Society adjourned for the day. In the evening receptions were held by Drs. Lawrence and C. S. Turnbull and by Dr. John V. Shoemaker.

The President, Dr. Henry H. Smith, delivered his address in Association Hall, when he said that the recurrence of the period when delegates from all our County Medical Societies assemble to

interchange professional opinions and renew or form the fraternal ties of a distinguished brotherhood, has again brought us together on this the thirty-fifth annual session of the Medical Society of the State of Pennsylvania.

This theme I would formulate as the

IMPORTANCE AND USEFULNESS OF SCIENTIFIC ORGANIZATIONS

to our profession and the public.

In order correctly to comprehend the objects obtainable by such organizations, it may be useful, 1st. To note their origin and elementary form, as described in history; 2d. Show in what manner our annual meetings are useful to the profession and the public; 3d. Allude to the reciprocal obligations of the public to the profession.

The Doctor then referred to the history of the first societies organized.

In the association of individuals that thus formed societies, it soon became apparent that some laws or rules of action applicable to each and every member must be adopted, in order to regulate intercourse and restrict irregular or individual opposition to the interest of society, and that in these laws, as in those of all communities, the most important portion would be "the penal or vindictory clause," it being useless to say, Do this or avoid that, unless the law also declared what would be the penalty or consequence of non-compliance. Ethics, or the law of manners, collected in a paper-book, termed Codex or Code, was thus adopted at an early period in the history of all associations; and the Code of Ethics of the American Medical Association is but another illustration that "history repeats itself."

The origin of our own State Society dates back only to the year 1848, when the pre-existing County Societies of Chester, Philadelphia, and Lancaster, elected delegates to a Medical State Convention that assembled in the city of Lancaster, to take the necessary steps to create a State Society such as was required to form a part of the American Medical Association.

A question that has been warmly discussed in connection with this Code is the right of members of the American Medical Association, or a county society, to consult at the bedside or office, in regard to the diagnosis and treatment of disease, with those who practice and believe in an exclusive dogma, and especially that one revived by Hahnemann, of *similia similibus curantur*, or that "like cures like."

It matters little, in the consideration of this question, to ask how or why it arose. The propriety of such consultations is positively settled by the Code, and hence its repeal is advocated by that comparatively small number, especially in New York, who, perhaps, anticipate benefit from the change. Any one who reads the clause in reference to consultations will readily see that the Code recognizes the fact that two physicians of different medical creeds cannot agree on any question of pathology and therapeutics, when each is conscientious in the correctness of his own professional opinion.

The influence exercised by these annual meetings of our Society is, however, by no means limited to medical ethics, but extends to the entire community through the scientific work thus accomplished.

In reviewing all that this Society has done in the last thirty-five years, our increased knowledge of the best means of preventing or alleviating disease is very apparent.

No Post-graduate course of medical instruction, now so much in vogue, "with doctrines fashioned to the varying hour," offers more valuable information to a medical man than that afforded by the papers and discussions presented in our sessions.

Since 1848 many advances in pathology as well as in practice have been made in this body, and been subsequently developed for the public good.

In the annual reports made by the able chairman of the Section on Hygiene, and especially by him who has also for years faithfully served the Society in the care of its funds, how many suggestions have tended to secure the comfort and sanitary safety of many of the towns and villages of this great Commonwealth!

The fear of "taking cold," and suffering from exposure to fresh air, is one constantly brought to the notice of every physician. Whilst apprehensive of "taking cold," the public seldom recognize the danger of being too hot, or of living in a temperature that often exceeds 75° Fahrenheit, in which every aperture for the entrance of the fresh air, that is so essential to the health of a respiratory creature like man, is carefully closed.

Not only is there with many an ancient and popular dread of fresh air, but the evil influence of fresh *night* air is yet widely noticeable. Many, who admit to some extent the beneficial influence of fresh air during the day, will hesitate about breathing the same air after sunset—a prejudice of ancient date.

Among the varied papers read in our meetings of marked public interest, and indirectly connected with the fresh-air question, was one "On the Influence of Growing Plants on Lung Diseases," which those present at our last session can readily recall.

The experiments there stated also render it probable that ozone is generated by *flowering* plants, thus rendering them an active disinfecting agent. From personal observation of florists and gardeners threatened with consumption, the author of the paper says, "he is convinced that their health was greatly benefited by the influence of plant life and the temperature and atmosphere of green-houses" (not hot-houses).

Popular sentiment has for a long period been entirely different from this, and many who are well read yet regard the presence of plants in a chamber as injurious to health, from the supposed amount of carbonic acid gas given off by them at night.

It may not be inappropriate in connection with the subject of State Medicine, also to call attention to the propriety of memorializing the legislature to modify the present mode of capital punishment, and make it correspond with the scientific progress of the age.

Without discussing the necessity of such punishment, we may justly urge that as its main object is the removal from society of those whose lives are detrimental to its best interests, this should be accomplished in the least painful manner; and it does seem as if death by means of electricity should at present receive due consideration.

I feel that I advance the cause of humanity

when I direct attention to this subject with a view of obtaining legislative sanction.

The great advances made in chemistry, and our increased knowledge of pathology, have also greatly changed the treatment of disease and the administration of medicine.

I know that the popular idea is, that the regular, scientific practice of medicine has been greatly benefited in this respect by the introduction of homeopathy; but this is not so.

Why are we so generally designated as allopaths that even a Congressional bill contains the name?

The answer usually given is, an allopath is one who treats disease by large and nauseous doses of medicine, whilst a homeopath gives little tasteless powders and sugared pellets.

Now, nothing is more erroneous as a definition than this statement. The dose of a medicine has nothing whatever to do with the name of allopath or homeopath. The distinction between these two schools of medicine is founded on a much more serious difference.

As our Code directs us to be ever vigilant of the welfare of the community, and to give counsel on matters specially pertaining to our profession, I have thus imperfectly alluded to a very common error, the result of which may be briefly summarized as having shortened life and lengthened suffering. I trust, however, that in referring to the unscientific character of homeopathy as a medical doctrine, I may not realize the correctness of the statement of Macdonald in one of his essays, "that many forms of error, perhaps most, are better let alone, to die of their own weakness, as the galvanic battery of criticism only helps to perpetuate their ghastly life."

I have, perhaps, detained you too long from pleasanter engagements in thus alluding to topics known to many of you; but in doing so, I have endeavored to illustrate "the importance and usefulness of scientific medical organizations to our profession and the public."

If I have failed in this, I trust you will recognize the difficulty of properly discussing the subject in the portion of time justly allotted me. I have, as you will notice, abstained from reference to the progress of medical science during the past year, though it might have proved more attractive, as this subject will be ably presented by other members of our Society.

Permit me before closing to acknowledge my appreciation of the attention accorded me on this occasion, and to express the hope that the present session of the Society will promote not only the hygienic interests of the Keystone State, but also that of other communities.

THIRD DAY.—MAY 16.

At the morning session, Drs. Leidy, Daly, and Trill Green spoke in favor of a resolution requesting the members of the profession to aid the Anatomical Board in carrying out the acts of assembly relative to the distribution of cadavers for dissection. The resolution was adopted.

"THE VALUE OF PUPILARY SYMPTOMS IN GENERAL DISEASE—AN ANALYSIS OF ONE THOUSAND CASES,"

was read by Dr. W. S. Little, of Philadelphia.

After the hospitals for chronic disease had admitted ophthalmic surgeons, trained in special hospitals, to their wards, ophthalmic medicine rapidly developed, and soon hospitals for acute disease claimed their services. The past twenty years has been the era for developing ocular symptoms in general disease. Medical education has felt the same impulse, and post-graduate instruction is the outgrowth of the success of instruction in ophthalmic hospitals abroad and at home. Special hospitals for the eye and ear now include in many of our large cities a department for throat, skin, and nervous diseases.

Medical ophthalmoscopy has been the principal factor in developing ophthalmic medicine, lesions in the eye-ground being found in Allbutt's cases in 89 per cent., in Noyes' cases that I have studied in 73 per cent., in Gower's cases in 100 per cent.

In my case studied at Elwyn, Pa., the institution for feeble-minded children, under the care of Dr. I. N. Kerlin, I found lesions in the eye-ground in 13 per cent. the age of the patients and varieties of disease exhibited there rendering the percentage necessarily less than the others referred to.

The study of the visual field for perception of light and color is another means of help in studying general disease.

Ophthalmoplegia externa and interna has received the greatest attention of late. Pupillary symptoms belong under the head of ophthalmoplegia interna.

The statistics of many observers vary largely as to their presence in disease, especially of a nervous type. I have believed the variation to be due to non-recognition of the symptoms being produced by intra-ocular and extra-ocular conditions, only the latter are of any value in general disease, and the former must be excluded, unless both conditions are recognized.

Castiglioni found seventy-five per cent. among insane; Nasse, sixty-four per cent; Wennecke, twenty-four per cent. The study of Allbutt and Gower's cases affords me their presence in twenty-three per cent. of their cases in acute disease. Allbutt and Noyes, Insanity—.05 per cent. in insanity.

The development of theories of pupillary movements from ancient to modern times has changed as anatomical knowledge of the cerebro-spinal system has been rendered clearer and anatomy of the eye worked out; the influence of reflexes upon the pupil are now quite well-defined, and the pupil can be studied with better knowledge than formerly. In acute disease among Allbutt's and Gower's cases it has a prognostic value, in sixty-seven per cent. of the cases fatal results occurring.

After giving the physiology of pupillary movements and describing how to study the normal and abnormal pupil, the results of a personal examination of three hundred and fifty cases at the Institution for Feeble-Minded Children at Elwyn, Pennsylvania, under the care of Dr. I. N. Kerlin, are stated. The examination here was thorough, and intra-ocular and extra-ocular conditions, as a factor, studied. Ophthalmoplegia externa existed in only two cases. Ophthalmoplegia interna from cerebral causes, or associated with the disease exhibited, was present in seventeen per cent. as follows: Males, 17.4 per cent.; females, 17.3 per cent.

Varieties of pupil :

Maximum	6.2 per cent.
Minimum	4.2 "
Unequal	6.5 "
Hippus	0.2 "

Varieties of Diseases :

Imbecility {	High grade	9.7 per cent.
	Middle grade	14 "
	Low grade	12 "
Ideo-imbecile		28 "
Idiocy		41 "
Juvenile insanity		20 "
Epilepsy		37 "

Intra-ocular causes excluded in 20.9 per cent.

At the Male Institution for the Insane, S. E. District Penna., Norristown, Pa. :

154 males, 43.5 per cent. with pupillary symp.	
154 females, 35.7 "	" "
308 total, 39.6 "	" "

Varieties of pupil :

Maximum	11 per cent.
Minimum	12 "
Unequal	14.6 "
Immobile	1 "

Varieties of Diseases :

Monomania	16 per cent.
Melancholia, Acute	25 "
Melancholia, chronic	35 "
General Paresis	100 "
Imbecility	20 "
Chronic Dementia	39 "
Mania, Acute	35 "
Mania, Chronic	55 "
Mania, Recurrent	50 "
Epilepsy	66 "

My work being done in institutions whose medical officers reputation in diagnosing the disease treated there, renders my statistics more valuable. For the facilities granted and enjoyment my thanks are due.

One thousand cases have thus been studied :

602 males, 22.4 per cent. pupillary symptoms.	
398 females, 24.8 "	" "
1000 total, 23.5 "	" "

"ALARMING AND DANGEROUS DOSES OF THE MYDRIATICS,"

was the title of a paper by Dr. Edward Jackson, of West Chester, who said that as it is important to understand the limits which are imposed upon the dose of atropia and other mydriatic alkaloids by danger of fatal poisoning, this paper has been prepared to remind practitioners that these limits are not really so narrow as many seem to think. Atropia being generally used in doses of one milligramme (one-sixtieth of a grain) or less, the impression grew that it would be dangerous to greatly exceed that amount; and this impression was strengthened by the fact that somewhat larger doses were apt to cause the common symptoms of atropia intoxication. But among two hundred and fifty-seven reported cases of poisoning by the various mydriatics, only seventeen had proved fatal—while the whole number of fatal cases of mydriatic poisoning to which even the slightest allusion had been found was, for belladonna and its preparations, eleven; datura, twenty-

ty-five; and hyoscyamus, two; and it was probable that some of those caused by datura were counted twice.

The paper contained quotations and abstracts of such of the above cases as bore directly on the subject under discussion, among them twelve cases in which the amount of atropia taken was known to exceed one half-grain, yet the patients recovered. Allusion was also made to the report of Dr. Fuller, of London, on the extreme tolerance of belladonna shown in choreic children, one taking as much as seventy grains of the official extract daily, and another taking thirty-seven grains of atropia in eighteen days. In the case of acute mania reported by Dr. Sydney Ringer, one-grain doses of the crystallized alkaloids, atropia, daturia, and hyoscyamia, were repeatedly given with benefit to the patient.

It was urged that, knowing these facts, practitioners should not hesitate to use this class of remedies more freely, whenever such use of them seemed indicated, special reference being made to the preservation of eyes from damage by iritic adhesions.

Then followed

"A FORM OF EPITHELIAL MYCOSIS,"

by Albert G. Heyl, M. D., of Philadelphia.

The disease described in this paper has long been known to ophthalmologists, and has been principally studied by them. In its graver forms the general symptoms are of far more importance than those observed in the eye, as the disease is frequently fatal. It is, therefore, opportune to give an account of some recent researches which have cleared away a great deal of obscurity which has invested the subject. This disease has been known under various names, *e. g.*, corneal gangrene, kerato-maleia, ophthalmia Braziliiana, etc. Graefe described it under the title of corneal ulcer of infantile encephalitis; his idea being that the corneal affection was of atrophic nature, the primary cause being an encephalitis. Gastrowitz has made this hypothesis untenable, by showing that these supposed encephalitic products are simply the remnants of foetal life. Leber, within a few months, has given a full description of a parasite found *intra vitam* in the conjunctival debris, and post mortem in the epithelium of the renal pelvis and in the small intestine. This parasite attacks the epithelial cell, inducing fatty degeneration of its structure. The dead cells accumulate in lamina, giving rise to a characteristic dry parchment-like appearance, the so-called conjunctival xerosis. The disease is usually ushered in by hemeralopia. This symptom, which is associated with the conjunctival xerosis, may last a month or two when corneal ulceration commences.

About this time general symptoms appear. There is rise in body temperature, frequency of pulse, a dry, harsh condition of the skin, the hair on the head becomes dry, lusterless. Along with this a peculiar state of apathy is developed. Persistent purging and vomiting occur, and finally broncho-pneumonia, to which the patient succumbs. All cases do not run precisely this course. Some do not proceed beyond the stage of of hemeralopia, in others the corneal ulceration appears after the inception of the general symptoms. In some the apathetic state is the most

striking symptom. In some constipation exists instead of the purging. The existence of a parasite in the conjunctiva in this disease was known before Leber's researches. But Leber has not only given a clear account of it, but also shown that it attacks the epithelial cell, and that it is found in other localities besides that of the conjunctiva. Probably the symptoms of the disease are traceable to this epithelial mycosis. Dr. Heyl gave adduced reasons for considering the epithelial cells as the receptive organ of centripetal nerves. Destroy these receptive organs in the conjunctiva and certain impressions of light will fail of being conveyed to the proper centre. A distinction was drawn between those impressions which, coming from the outer world, may issue into voluntary action and those which issue into involuntary action. Thus the sensation of light, and that impression of light which is followed by the reflex movement of the lids, are two different things. It is the latter which is absent in this disease by reason of the destruction of the terminal epithelial cells by which it is accomplished. The same rationale may be applied to the skin, which is a vital organ containing a principal part of the thermic apparatus. The epithelial cells may be looked upon as the receptive organs through which the sweat-glands are set in action. Destroy these, and the function will be abrogated. Thence the apathetic state and, possibly, the broncho-pneumonia are developed. The purging and vomiting seem to be due to the direct presence of the parasite. In the treatment, the careful administration of food is important, and as the application of moist heat to the eye has been found very serviceable, possibly it would also be if applied to the surface of the skin.

After which Dr. Carl Seiler of Philadelphia read a paper on

"AN ELECTRIC LARYNGOSCOPE,"

in which he described an apparatus for the illumination of the laryngeal, nasal, and other cavities of the body by means of an electric incandescent lamp. He first gave a short historical sketch of the experiments made by others in the same line of investigation, and described the instruments invented by Adams, Trouve, and others, and then gave a detailed description of his instrument, illustrated by a demonstration of its capabilities for practical use in examining the laryngeal and nasal cavities.

The instrument consists of the ordinary head reflector, attached to which is an arm of metal four inches in length, which carries on its end a small incandescent lamp, lighted by electricity by a current from a battery. The light of the lamp is reflected from the head mirror into the patient's mouth, and is then reflected downward by the ordinary laryngeal mirror. A shield of silvered mica is placed around the anterior portion of the lamp to prevent the light from falling directly into the patient's face, and also to utilize all the light given off from the incandescent carbon filament. The apparatus is light and easily carried on the forehead of the operator, and has the advantage over the head mirror without the lamp attachment, that when the reflector is once adjusted on the forehead, the light is always

thrown in the direction of the axes of the eyes. It has also the advantage over similar instruments that it can be used for the examination of the eye as well as of the ear, since the operator can bring his pupil before the central perforation of the reflector; and should the source of electricity give out unexpectedly, which will frequently happen when the operator is not sufficiently conversant with the tricks of batteries, the head mirror can still be used in the ordinary way by reflecting a stationary light.

Then followed a paper entitled,

"DOES A CHRONIC DISCHARGE FROM THE EAR MAKE LIFE INSURANCE HAZARDOUS?"

by Dr. Charles S. Turnbull, of Philadelphia, who calls attention to a point of vital interest to life insurance companies and their medical officers. He describes the too frequently hazardous condition of those persons making application for life insurance policies, holding that some of these, while passing a first-class physical examination, may at the same time be suffering from fatal discharge from the ear.

He maintains that whatsoever the plan may be, whether mutual, life, or endowment, the risk incurred and the liabilities assumed by life insurance companies, through their medical examiners, is in no small way compromised by the existence of a chronic ear disease of the applicant to be insured.

Deaf persons are not insured by the leading life insurance companies, at least not at ordinary rates, because of the self-evident fact of their being in imminent peril; hence, such are not considered, or are accepted as "extra hazardous."

An otorrhœa may exist and be entirely overlooked by experienced examiners, and this is, in his opinion, in many cases a much greater source of danger to life than that arising from the mere physical defect of not hearing. Deafness of a dangerous or hazardous degree cannot be concealed, and is only an element of risk in so far as accident is concerned; while a chronic purulent inflammation of the middle ear, with, perhaps, some polypoid or necrotic complications, can be intentionally or unintentionally concealed, or on the other hand be overlooked, while it threatens life within a year. One remaining sound ear may do all the work, and the examiner, as well as intimate friends, may never suspect the defect. Total deafness, like total blindness of one side, may exist for years, even a quarter of a century, without even the afflicted individual being aware of the fact, and a purulent discharge continue from childhood without causing annoyance, or indeed even a thought.

He suggests an ocular inspection of the ears, and at times, when of sufficient importance, the employment of an expert, because in his experience he had known of liabilities incurred where even a hasty examination of the ear would have saved the insurance companies thousands of dollars.

The same may be said with reference to the organs of sight.

He concludes by urging the profession to exercise more care in the treatment of the ear-symptoms and complications in the exanthemata, and likewise calls especial attention to the importance

of the insurance companies making the examination of the ears compulsory in every case.

As an easy yet complete method of examination of the ears, he suggests the following, which places the examiner in a secure position, and makes him entirely independent of the statements of the examined, as well as of instruments of precision, or reflected light:

1. *Test each ear separately with the watch, the eyes being covered.*

2. *Inspect by good daylight the auricular region, especially noting condition of mastoid or cicatrices thereabouts.*

3. *Inspect (nasally, as do the gas-fitters) each auditory meatus, and;*

To sum up—what the impaired hearing does not suggest, cicatrices from loss of bone or fistulous orifices over temporal bone, will point out; while the presence of pus, or what is more significant, of fetor, will settle the question.

A purulent discharge from the ear should always raise a question with insurance companies, and its character and ultimate course as to the future health of an individual can only be settled by an acknowledged expert, *i. e.*, men of experience must say whether it be curable or not, so that full justice may be done both examined and examiner.

Dr. P. D. Keyser read a continuation of his paper entitled

"OPHTHALMOLOGICAL OBSERVATIONS DURING TEN YEARS' SERVICE IN THE WILLS EYE HOSPITAL."

He described a cystotome of his design for rupturing and drawing up of the anterior capsule for the removal of a piece of it in the operation for extraction of cataract. He gave his modification of Pagenstecher's operation for the removal of pterygium; and also the history of an interesting case of complete paralysis of the sixth pair of nerves from injury to the head, causing extreme double convergent strabismus, which was relieved by operation of shortening and bringing forward the external recti muscles.

Four cases of glioma of the retina were narrated, two which were operated upon by enucleation, and the macroscopic and microscopic account of the balls given.

Dr. John B. Roberts read the address in surgery, entitled

"SURGICAL DELUSIONS."

Many surgical theories and procedures have become traditional, and are accepted as true and correct, merely because reverence for antiquity or careless acceptance has not questioned their right to be classed as surgical facts. The present age is an incredulous one, and demands accurate investigation of all such claims. The field of investigation is large, for progress has been retarded by the influence of theorizing writers and monochromatic vision, the example of non-seeing and non-looking devotees of the fetiches of surgical superstition, and the convincing effect of a repetition of false statements. I shall select a few topics which have greatly interested me, and concerning which I probably differ quite widely from many of you.

Chloroform Anæsthesia.—Many still cling to the delusion that chloroform is a safe anæsthetic, because they have never seen a patient die from it. Is one man's experience to weigh against the physiological, the experimental, the clinical experience of the whole world? Dare we employ chloroform instead of ether, when recognized authorities state that in chloroform anæsthesia death occurs without warning in the hands of experienced administrators, when some five hundred deaths have already been reported, when Schiff and Dalton reject it in physiological laboratories because of its mortality, when the Scientific Grants Committee of the British Medical Association assert that chloroform is a more dangerous anæsthetic than ether? Adherence to chloroform in the face of such facts is criminal, when circumstances permit ether to be obtained. The assertion that it is often impossible to produce anæsthesia with ether is the result of inefficient methods of administration. Ether, if given as chloroform is and should be given, is in truth a useless anæsthetic, but given properly it is efficient.

Value of Styptics.—The belief in the necessity of styptics is a delusion less dangerous than that just mentioned, but is given more extended credence. Such agents are seldom, probably never needed in general surgery to arrest hemorrhage. When ligatures, torsion, or acupressure is not demanded (and such is seldom the case unless the artery is as large as the facial), moderate direct pressure applied in dressing the wound is the only hemostatic required. Styptics often do harm, and, as they are not needed, they should be discarded.

Fatality of Small Hemorrhages.—There is much misapprehension about the quantity of blood that a healthy man can lose with impunity. Many who often look with equanimity upon a parturient woman losing a pint of blood from the uterine sinuses, would be dismayed at a man losing half or quarter that amount during removal of a tumor. While not advocating needless waste of blood, and especially in patients suffering surgical shock, I assert that there is an unnecessary fear of blood spurting from a few insignificant vessels. The largest artery can be controlled by pressure not greater than is used for ringing the electric bell in your hotel. Hence there is always sufficient power in your fingers to obviate hemorrhage until strings can be obtained and applied.

Danger of Trephining the Skull.—The dislike to make exploratory incisions in closed fractures of the skull evinced by some surgeons, and the objection of others to trephining, and thus opening the diploic structure in open fractures, are delusions of a most disastrous tendency. To wait until symptoms of cerebral compression or inflammation have supervened, is to lose the most favorable opportunity for mechanical relief. Such a Falian policy is often followed by death. The treatment of open and of closed fractures of the skull should not be looked upon as very different, since with the present improved methods of dressing wounds the successful issue depends almost entirely upon the cerebral rather than the cranial phase of the injury. If such fractures as are usually seen in the skull were not in proximity to the brain, the surgeon would consider them almost trivial. The feature of closed frac-

tures that renders them so troublesome is the obscurity that accompanies them. I have, for a number of years, strongly advocated making closed fractures open ones by means of an exploratory incision, whenever there is a suspicion of the existence of depression or splintering. In open fractures, operation to elevate depressed portions and get rid of splinters of the inner table thrust into the membranes should be undertaken rather than avoided. It is better to err on the side of action than that of inaction. Careful manipulation and proper dressings at an early stage are sources of less risk than is incurred by the surgeon who leaves unseen and unsuspected fragments thrust into the membranes or brain.

Operative Delay in Strangulated Hernia.—A similar delusion of fatal issue is that leading to postponement of the operative interference in strangulated hernia. Repeated attempts at forcible taxis and medical pow-wow with temporizing measures have ended more lives than the use of the knife. Herniotomy done within twelve hours is almost always followed by recovery. Death is to be expected, however, if strangulation has existed for two or three days, and the gut has been bruised by violent manipulation in the endeavor to relieve the constriction by taxis. Moderate taxis under ether, a half day's treatment with cold applications and the internal use of morphia, and a second moderate attempt at taxis, followed, if unsuccessful, by immediate operation, is the sequence to be followed in strangulated hernia. When symptoms of strangulated hernia exist, the slightest fullness and tenderness in one groin over either of the rings is a sufficient localizing indication to warrant operation.

Operative Delay in Acute Phlegmonous Inflammation.—No insane delusion, no Spanish inquisitor, ever caused so many hours of excruciating physical torture as the hallucination that acute abscesses and furuncles must not be incised until pointing has occurred. All the world knows that evacuation of imprisoned pus in phlegmonous inflammations means instant relief of the agonizing pain; yet how few of the profession early and freely incise such inflamed tissues, unless they first see the yellow pus under the thinned skin, or feel the fluctuation of the fluid in the abscess cavity? The pain is caused by the effort of the pus and sloughing tissue to escape. Is it not, then, more rational to make a free incision to-day than to wait till next week? Time and pain are both saved by early incision. If the cut is made before the pus has actually formed, so much the better. Probably no form of abscess needs early and free incision more imperatively than that under the palmar fascia. Destructive burrowing of pus is prevented by this radical procedure, which, also, saves the patient many days of poultices and purgatory.

Operative Delay in Malignant Tumors.—Much bad surgery results from a delusive postponement of operative interference in malignant diseases. Instant removal is to be practiced in such cases, provided the patient is deemed fit to stand the surgical shock.

Necessary Fatality of Traumatic Tetanus.—That traumatic tetanus is of necessity fatal is a commonly held opinion. Proper treatment is sometimes neglected because of this belief in its hope-

lessness. That the prognosis is extremely unfavorable I admit, but that cases of a severe type recover is undoubted. Chloral hydrate in full doses has given the best results; but I do not propose speaking of therapeutics at this time—I merely wish to impress upon the profession the fact that a fair number of cases of traumatic tetanus recover.

Fatality of Pericardial and Cardiac Wounds.—The prevalent notion of the excessive danger of these wounds is delusional, at least in as far as it teaches that these structures will not brook surgical interference. The pericardial sac should be dealt with exactly as the pleural sac, by aspiration, incision, irrigation, and drainage, according to the lesion. That simple puncture or aspiration of the heart itself is not accompanied by the expected risk to life has been pretty well shown, though I am not prepared to recommend its general adoption for trivial cardiac conditions.

Symmetry of Normal Limbs. Another delusion still existing in many minds is that the lower extremities are usually of the same length. Clinical and anatomical investigation show that asymmetry in the length of normal limbs is a common occurrence. Therefore, measurements of the legs in cases of fracture are of little value, since it is impossible to know whether it is the femur of a long or a short leg that is the seat of injury.

Uselessness of Treating Vicious Union of Fractures.—It is a fact not sufficiently appreciated that many cases of deformity from imperfectly treated fractures of long bones can be remedied by refracture. Over and over again have I seen cases of grave disability and deformity cured by the application of sufficient force to break the callus uniting the misplaced fragments. Five or six months is not too late to resort to this expedient for correcting what otherwise must be a life-long evidence of defective surgical attendance.

There are many other prevalent surgical delusions, such as: that bony union of transverse fractures of the patella and of intracapsular fractures of the femoral neck cannot take place; that chronic purulent discharges from the ear do not need active treatment, that hypermetropia and hypermetropic astigmatism can be properly estimated and corrected without paralyzing the accommodation; that it is improper to perforate the nasal septum in cases of great deviation; that crooked noses are not amenable to treatment; that corneal operations and cataract extractions should be treated by cotton padding and bandages to the eyes; that fractures should be treated with carved or manufactured splints.

While an earnest advocate of conservative and of reparative surgery, I believe that when operative surgery is demanded it should be aggressive. Delay, indecision, and inefficiency impair the value of much surgical work, and are often the legitimate result of a superstitious faith in delusive surgical dogmas.

Then followed the paper by Drs. Edward T. Bruen and J. William White, which we publish elsewhere.

Dr. Nancrede then read a paper on

"THE BICHLORIDE OF MERCURY AS A SURGICAL DRESSING."

The next paper on

CLUB-FOOT. IS TARROTOMY NECESSARY IN CHILDREN?

Was by Dr. De Forest Willard who presented a patient (together with photographs and plaster casts) upon whom he had operated two years ago for an extreme degree of varo-equinus, congenital and double. The girl had been subjected to tenotomy when an infant by a homoeopathic surgeon, but as he never returned to the house after the operation, it may well be imagined that little benefit was secured, and the result was that the parents were so prejudiced against any interference that they permitted the child to go untreated, and, running around in her bare feet, she had, when seen at the age of eight, produced the deformity shown in Fig. 1. (Front view. From a photograph.)

FIG. 1.

The outer dorsal aspects, protected by large bursae and callosities of the size of small oranges, were in contact with the ground at each step, while the toes presented backward, and the plantar surfaces looked outward, owing to the great inversion of the legs in the effort not to strike the toes in the "reel-foot" action. This inward twist was most marked at the left knee, and the anterior surface of the tibia was rotated at least 30° on its long axis from its normal relation to the femur, thus causing the calf of the leg and the deformed heel to present directly outward. The legs were atrophied, the astragalus and cuboid very prominent in both feet, and the deformity at the medio-tarsal articulation sharp and abrupt. Strong pressure caused but little change of position in either foot, and the tissues of the soles and inside portions were extremely dense. The left foot was somewhat worse than the right, and its position was aggravated by the twist above mentioned.

The plan decided upon was to freely divide the tendo achillis and the tibials, as well as all the contracted tissues upon the inside of the sole save the skin, and then apply manual force sufficient to restore the limb, *redressement forcé*, as, even should the calcaneo-scapoid ligaments yield, the trouble would still be subcutaneous, and therefore have

every advantage over an open incision. Failing by these means to strengthen the foot, a wedge-shaped tarsotomy would be performed.

The sections were made, as proposed, with a tenotome, first, of the anterior and posterior tibials, then of the long flexor, and then everything upon the inside of the sole was divided, the tendo achillis being left until near the end of the operation, in order to gain increased power in untwisting the varus. After long and severe stretching, the left foot was brought into good position, and section of the bones was decided unnecessary.

On the right foot, an assistant, who was an exceedingly strong man, applied unnecessary force, and the internal lateral ligament of the ankle was heard to snap, the foot at once sliding a little toward the fibular side. In consequence of this accident, which ultimately, however, proved beneficial in giving a straighter foot than the left one, the tissues upon the inside gave way at the first dressing, opening directly into the ankle joint; but thorough drainage and dressing with carbolized oil succeeded in closing the wound in about six weeks.

Both feet were placed in gypsum splints, which were afterward fenestrated for observation, and later, the author's shoe was applied, tractions, massage, stretchings, etc., being continued for months. The shoe (Fig. 2) acts by elastic force, pulling upward and outward by means of webbing, which exerts its power through the intervention of a catgut cord passing through an eye.

FIG. 3.

As will be seen by Fig. 3, taken from a recent photograph, the patient walks upon the soles of both feet, and although there is slight deviation at the medio-tarsal joints, yet it would scarcely be noticed in the right foot, and in the left does not interfere with walking nearly as much as does the rotation at the knee-joint, which was so marked a feature in this case.

To correct this deviation of the tibia upon its long axis, spiral spring action taking its support from the pelvis (as in the apparatus of Dr. Gregory Doyle) has been tried with some benefit; but no operative procedure promises much success, and the patient is being educated to walk with out-turned toes, which she is perfectly able to do when her attention is fixed. The patient wears an apparatus upon both feet, although she can walk

FIG. 2.

perfectly well upon the right foot without it. She uses no cane, and can easily accomplish a mile. There is rigidity of the right foot, but she climbs stairs without assistance.

Dr. Willard said that when he first saw the patient, he felt that a wedge section would be required, as the deformity was most rigid and extreme. He was now satisfied, however, that the child had better walking feet than she would have had after tarsotomy.

He then reviewed American, English, German, and French authors (these quotations will be published in the *Transactions of the Pennsylvania State Medical Society*), showing that the majority of patients, after section of the bones, either walked with the aid of apparatus, or had very rigid feet, or required further interference surgically, so that after running the risk of a serious operation, which had destroyed several lives, they were really in no better condition, and had not as flexible feet as those who had been the subjects of tenotomy and stretching.

Tenotomy was a safe operation, and after tedious resistance had been overcome, he was not afraid to use what some might call extreme force, since the rupture of a ligament, or even the fracture of a bone subcutaneously, was a small matter compared to the opening of cancellous tissue, and the starting of an inflammation in the tarsal joints, which are so prone to destructive change.

Antisepticism had undoubtedly rendered the operation far safer than in former times, but the risks of subsequent caries could not be wholly avoided.

Davy had certainly been exceedingly fortunate in his twenty-two cases reported up to June, 1882, with but one death from septicæmia; yet even four and a half per cent. of deaths was great when compared with the innocuousness of tendon division. One certainly could not see sufficient reason for his risking so serious an operation upon an infant sixteen months of age, in whom the bones could not yet have become wedge-shaped

from walking pressure, and in whom *redressement forcé* would probably have secured an excellent result. The intelligent exercise of even great force, when regulated by the hands of a practiced surgeon, would seldom produce serious injury.

The speaker then quoted from several authors as to the extent to which such force could be carried. Subcutaneous section of the calcaneo-scaphoid, and other, tarsal ligaments, as practiced upon other articulations of the body in old dislocations, etc., would be preferable to open incision as performed by Phelps and Post.* In adults, where the bones had become badly distorted and wedge-shaped, in which cases there had formerly been only two courses of treatment to be pursued, *i. e.*, either the "let-alone policy," as advocated by Guérin,† or amputation, Dr. W. believed that tarsotomy offered a decided advantage; but in children under ten, he would thoroughly test the virtues of powerful force, associated with subcutaneous sections, before resorting to the graver expedient. Not every case that has relapsed after tenotomy, was incurable, since kind(!) parents frequently defeat the best efforts of skilled surgeons. It was in these cases of rebellious parents that plaster of Paris has proved a most useful assistant, taking the control of the case entirely out of the interference of patient or friends.

As regards the forms of operation, *i. e.*, partial anterior tarsotomy, or excision of the cuboid; complete anterior tarsotomy, or wedge-shaped incision by saw or chisel; and posterior tarsotomy, or resection of the astragalus, the speaker believed that as both the former and the latter were uncertain and often insufficient in results, that in those cases where the operation was demanded it should be complete, the wedge being so shaped that it should present two bases, one looking outward, the other toward the dorsum, in order to preserve to a certain extent the normal arch of the foot.

In the eighty (80) operations upon sixty-eight (68) patients which he had collected, wedge-shaped tarsotomy was done fifty-eight (58) times upon 50 cases, with 3 deaths; the astragalus was resected 13 times on 11 patients, with no deaths; and the cuboid, 9 times in 7 patients, without a death. One patient died of septicæmia, one of hospital gangrene, and one of an old and serious heart complication. It has been well remarked that this operation should be viewed in two lights—one as regards its danger, the second in relation to its ultimate results in giving useful feet.

The conclusions drawn were:

1. In children under ten, even in extreme degrees of deformity, powerful manual force, with subcutaneous division of the contracted tissues, will restore the foot without section of the bones, and should be first attempted. The degree of force required may be great, but even if carried to rupture of the tarsal ligaments still leaves the injury subcutaneous.

2. Fixation in the straightened position is best maintained by plaster-of-Paris dressings for a few weeks, after which daily stretchings will give a more pliable and better walking foot than is obtainable after tarsotomy.

3. Cases should not be considered incurable by moderate means, simply because they have relapsed after imperfect treatment. Careful supervision may still accomplish a good result.

4. Tarsotomy is a valuable operation in old cases wherein the bones have become wedge-shaped and irreducible. It should always be done antiseptically, and the removal of a wedge-shaped piece by saw is preferable to excision of either cuboid or astragalus.

5. Three deaths in fifty-eight cases of tarsotomy shows the great danger of the operation as compared with tenotomy, in which there have been scarcely that number of fatal results in the thousands of cases operated upon.

Dr. Joseph B. Potsdamer followed with a paper entitled,

BRONCHITIS AND PNEUMONIA OF RHEUMATIC ORIGIN,

in which he said that the most voluminous writer on this subject is Dr. Thos. H. Buckler, of Paris. Laennec described this affection under the term "dry catarrh." Trousseau, in his "Clinical Medicine," vol. 2, page 663, ed. 1873, Philadelphia, gives a description of rheumatic pneumonia.

The anatomical seat of this disease is in the white fibrous tissue of the bronchi, which is inflamed. It does not affect the mucous membrane primarily. Pneumonia is always secondary to rheumatic bronchitis, and may occur in the same lung. Proper rheumatic treatment will often save the patient. Further, it bears a direct relation to general rheumatism and rheumatic endocarditis.

In pneumonia there is congestion of the capillaries of the depurative circulation. On the other hand, congestion or inflammation of the bronchial structures affords an example in which the capillaries of the nutritious arteries and veins are involved.

The symptoms of the acute variety of rheumatic bronchitis are profuse, irregular sweats, inordinate sensibility to cold, transient and irregular flushings of the face, and either a constant or a paroxysmal and unproductive cough. pulse and respiration not much altered. Pain most constant on coughing. Rheumatic bronchitis degenerates into a chronic form, with dry cough, rapid respiration, and occasionally aerated mucous expectoration. Auscultatory signs are negative, except an occasional sibilant râle. The diagnosis is usually made by exclusion. Supervention of cardiac disease is of great value in diagnosing the present affection.

In rheumatic pneumonia there is almost always a premonitory cough; in idiopathic pneumonia there is none. Rheumatic bronchitis is a most insidious disease, going on for months, at times with no further annoyance than is produced by a dry cough, occasional slight chest pain and soreness, the patient feeling no indisposition, having a good appetite, sleeping well, and attending to business as usual. Symptomatic pneumonia is always preceded by rheumatic bronchitis. It may present all the symptoms of idiopathic pneumonia, but what gives it its distinctive character is, that all the symptoms of pneumonia may suddenly disappear without the gradual decrease observed in inflammatory pneumonia, and it is usually confined to a smaller section of the lung tissue.

*New York Med. Record, 1881, xx., p. 337.

†Bull. Acad. Méd., Paris, 1882, p. 1039.

The prognosis is favorable, provided the disease is recognized early, otherwise the pneumonic process may go on and the patient succumb, or the lung may break down and the patient eventually dies of consumption.

The treatment is the same as is indicated in acute rheumatic affections elsewhere. Salicylic acid and its salts or phosphate of ammonia being given, when uric acid and urates are found in the urine; lemon juice, when phosphates are present.

The next paper was on

CHRONIC ARTICULAR OSTEITIS OF THE KNEE-JOINT.

Dr. A. Sydney Roberts, of Philadelphia, read a paper on this subject, in which he said that he had chosen the term chronic articular osteitis as the one best expressing the pathological condition found in those lesions of epiphyses of the knee-joint that have usually been described by the older writers under the caption "Tumor Albus."

His reason for so doing has been by proper classification to refer directly to inflammation of the cancellous structure of bone, thereby avoiding the confusion that usually exists if the more general terms *arthritis* or knee-joint disease be employed. Before considering the main feature of the paper, viz., to bring before the Society a new mechanical splint, designed for the treatment of chronic articular osteitis of the knee-joint, Dr. Roberts hastily reviewed the etiology and pathology of the affection.

To meet the universally-recognized principles of treatment, *i. e.*, fixation of the joint and extension, he has designed the splint that he now feels justified, from the success that has attended its use, in presenting to the profession. It consists of two light steel padded troughs, that are firmly secured to the limb by encircling bands of surgical webbing, affording absolute fixation to the joint, when the extending rods are locked after adjustment. Three ratchet extension bars arranged in the form of a triangle are placed posteriorly corresponding to the long axis of the limb, placing within the control of the surgeon a power that will overcome the flexion and the tendency to the production of deformity, and at the same time produce extension. The extension rod acts directly upon the head of the tibia, and parallel with the line of contraction of the flexor group of muscles, obviating thereby the error in the mechanical arrangement of the popular Stromeyer's splint, or in all where the power is applied low down on the tibia to overcome flexion.

After which the Society adjourned.

In the evening receptions were held by Drs. P. D. Keyser and John B. Roberts.

Adulterated Butter and Cheese in New York.

The New York Legislature has just passed the bill which has been under discussion for some time, prohibiting the sale or manufacture of all adulterations of butter or cheese. It is to take effect on July 1, 1884.

The careful investigation carried on by the committee of the Legislature brought out many curious and disagreeable facts. It was shown that the manufacture of oleomargarine might be cleanly, and the articles used not unhealthy; but that in many cases this was not true. It also appeared

that it was often difficult to detect the difference between genuine butter and oleomargarine, except by the use of chemicals, and that oleomargarine was never sold under its real name, but as real butter. It was therefore recommended that the manufacture and sale be absolutely prohibited, as all attempts to regulate the business had failed. A bill embodying this recommendation was introduced, and has now passed both the Assembly and Senate.

The Woes of Importing Chemists.

A number of the importing firms of New York city dealing in dye stuffs, chemicals, and drugs, have sent a memorial to Congress requesting that an investigation be made as to the methods of doing business carried on in the Appraiser's Department of the New York Custom House. They claim that their business is delayed and made harassing and expensive by the reckless charges of under-valuation preferred against them by the custom-house officials—charges which have always been shown to be groundless. They state that they are unable to get possession of their goods after the custom-house has gotten hold of them, except after long delays, and that it frequently happens that goods needed for speedy delivery are held one, two, or three months. In some cases the importers are put to heavy loss because they are unable to fulfill their contracts. The custom-house officers deny these statements, and claim that their action was necessary to prevent frauds on the revenue. It is thought that an investigation will be ordered by Congress into the whole matter.

Items.

—In 1878 the importation of quinine was 17,549 ounces; in 1883 it was 1,055,764 ounces.

—At the recent convention of cane growers at Topeka, Kansas, it was shown that during 1833 Kansas surpassed all the other States in the Union in the production of sorghum sugar.

—It is asserted in the *Pharmaceutical Record*, May 1st, that if bees are kept in any locality where aconite grows, and collect the sweets from its flowers, such honey will exhibit the poisonous quality of that drug.

—Hogs in and around Denver have been dying in great numbers from lung disease. The appointment of a swine inspector at Denver is talked of, as it is supposed some of the diseased animals were disposed of there for human food.

—The American government has received an invitation to participate in an exhibition of dairy products at Munich, in October, 1884, under the management of the General Committee of the Agricultural Union of Bavaria, in connection with the Bremen Dairymen's Union.

—A western editor received a letter from an indignant subscriber, who said: "I don't want your paper any longer." To which the editor mildly replied: "That is all right. I wouldn't make it any longer if you did, because in that case I should have to buy a new press. The present length just suits me, and I am glad it suits you." It is to be hoped this "soft answer turned away wrath."

WORK OF WOMEN PHYSICIANS IN ASIA.

BY MARY H. STINSON, M. D.,

Of Norristown, Pa.

(Continued from page 652.)

Since 1869, there have been sent to India 15 women medical missionaries, one for each year since that time.

By The Woman's Bd. of For. Miss. of the Pres. Ch.....	1
" " " " " Am. For. Miss. (Congts.).....	1
" " " " " Union Miss. Society.....	2
" " " " " Lutheran Church.....	1
" " " " " Woman's For. Miss. of the M. E. Ch.....	5

I have received replies from five of these medical missionaries to inquiries concerning the diseases of women and children. The diseases of the latter seem to be about the same as with us, but of a milder type. They do not mention scarlet fever or diphtheria, but eczema is much more common, and there is some leprosy and dengue among them. Concerning the age of puberty it was difficult to be exact, as few knew their ages, but nine to fourteen years were the extremes mentioned. Mothers of thirteen and fourteen years were common. Their children were very small, but appeared healthy. Infant marriages were deplored. These often caused the wife to go to live with her husband before puberty—always as soon as the menses have occurred, when she becomes the slave of the mother-in-law. A large majority of the boys in the high school are fathers. What would you expect to be the mental capacity of the children of these boys and girls? There are now in India 21,000,000 of widows, many of whom are widows by the death of the

boys to whom they were betrothed in early childhood and were never married, but yet have to live under all the abuse and cruelties that are permitted to be heaped upon widows.

Labor was considered tedious and painful as a rule. Two reported the employment of midwives to be so universal that they had never been called to such cases.

Rupture of the perineum was very frequent, that of the cervix uteri less frequent. Diseases peculiar to women were of the same general character as at home, but aggravated by bad treatment during and after parturition, and by subsequent neglect.

Neuroses and insanity do not appear to be very frequent. Puerperal cases had been seen. Hard work and an undue anxiety to be mothers of sons were given as possible reasons thereof. The birth of daughters is a dire calamity.

To the question, "What provision is made for the care of the insane?" came, "Hospitals are provided." "The provision by the English Government is very primitive." "Government asylums badly kept."

Dr. Anna S. Kugler, late assistant physician in the Woman's Department of the Southeastern Hospital of Pennsylvania, who had been only a short time in Gunttoor, India, had learned of but one hospital for the insane in southern India, which was located in Madras. This she had visited, and was much pleased with its management, and they were having excellent results from the open door system.

In 1874, we should note two events: "The Medical Prayer Union" was established in London, which in 1878 numbered 220 doctors and

medical students. They met weekly for prayer and the study of the Bible. Also, when the University of Edinburgh was closed to women, the remedy was sought in the founding of "The London School of Medicine for Women," which was opened in October, 1874. Obstructionists prevented women being admitted for examination by the various medical boards until 1876, when an act to empower all medical boards to admit women became law. The Irish College of Physicians took the initiative, and within the last seven years 38 women have obtained diplomas from this college.

In 1878, the University of London, after a severe contest among its own members, agreed to admit women to its medical degrees. This led ultimately to their admission to all the faculties, and "it is understood that when certain new arrangements are completed between the Royal College of Physicians and of Surgeons of England, the admission of women to their examinations will be included in the programme, and this event will certainly give the final blow to the policy of male monopoly in medicine."

The course of study and of examination is very protracted in the University of London, and it is a very great satisfaction to be able to record that already three women have graduated as "M. B. Lond."; and that in two cases the golden medal of the University has been awarded to women, after competition with all the students of the year—in anatomy to Miss Helen Prideau in 1881, and in obstetrics to Mrs. Scharlieb in 1882.

One of these graduates of the London School of Medicine for Women, Miss Jane E. Waterson, M. D., is the first woman medical missionary sent into Africa, "that garden of the Lord in the wilderness, where the worship of God has been begun, schools opened, the slave trade suppressed, and the faith of the natives won."

Four of these graduates are practitioners in India: Bombay, Calcutta, Lucknow, and Madras.

A philanthropic citizen of Bombay has collected £26,975, and has the promise of £13,504, for the purpose of founding a hospital for women and children, the expenses of conducting the same, and to pay the salaries of one or two lady physicians. A large and influential committee, representing every section of the community, was organized for the purpose of promoting the object in view. This committee have invited Miss Edith Pechey, M. D., a graduate of Berne, but registered in London, to enter upon practice in Bombay, and to take charge of the Hospital for Women and Children, "with a liberal salary and excellent residence." The corner-stone of the hospital

was laid with great éclat, by H. R. H. the Duke of Connaught.

"While a majority of the Calcutta Medical College consider that the requirements of the country point rather to the provision of educated midwives and nurses than to full-blown lady doctors, the government of Bengal has assumed the responsibility, and thrown open the medical college and hospital to females. One young lady, B. A. of the Calcutta University, is now enrolled as a regular student.

"In Madras, lady students were admitted to the medical college in 1875 under special rules." One of these ladies was Mrs. Scarlieb, who obtained the "M. B. Lond." of the London University, and its gold medal, in 1882. It is now proposed to place her at the head of a hospital for women and children in Madras.

"Women in India have obtained liberty and encouragement to qualify themselves, under the same circumstances and advantages as men, for the practice of the profession of medicine, and the state is prepared to sanction their doing so."

The editor of the *Journal of the American Medical Association*, after reading such comments and such able editorials on this subject as appear in that country itself, writes: "We are suddenly, but satisfactorily, awakened to the fact that perhaps we are as green in our knowledge of that country as a Hatch or a Villiard Englishman is of this."

"The Woman's Foreign Missionary Society of the M. E. Church" has voted to raise \$25,000 for the establishment of the first woman's periodical in India. David C. Cook, of Chicago, has given a \$2,200 Cottrell steam printing press to the *American Mission Press* in India. This will be the first steam printing machine, except those of the government, in use in India.

Sir John Lawrence, who entered the lowest class of the English Civil Service in India in 1830, and rose through all its gradations to be Viceroy in 1863, said: "I believe, notwithstanding all that the English people have done to benefit India, missionaries have done more than all other agencies combined."

BURMAH.

Rev. E. P. Dunlap, of Siam, when urging an increase of the number of medical missionaries, wrote: "Even while the heathen, through prejudice, stand aloof from the preacher, they will seek the physician more and more after he has performed some of those cures which, to them, seem almost supernatural."

There are but two women medical missionaries

in all British Burmah, both under the Woman's Baptist Foreign Missionary Society. Mrs. Douglass, M. D., in Rangoon, who is turning her medical work to good account as a means of access to the people. "Oh! for workers among the Burmans. There is an eagerness to hear the living word among the dwellers in the jungles."

In Maulmain, Dr. Ellen E. Mitchell has been assisted by a native Christian, Dr. Shaw Loo, who has greatly relieved her in some departments, and reached families, both as a physician and as an evangelist, in a way which she could not. Her patients were from eight different nations or tribes, with almost every disease that could be mentioned, though fevers, ophthalmia, coughs, rheumatism, diarrhoea, dysentery, and various skin diseases, were the most common complaints. Nearly the whole work has been gratuitous. Medicine has done much towards opening doors otherwise closed to us.

CHINA.

The portion of the great empire of China into which women medical missionaries have been sent, lies along the eastern coast at intervals from 23° to 41° north latitude. Peking, the capital, being 40°, and in but 10° of its 40° of longitude.

We are not aware of any regular system of medicine in China. Medical knowledge is rather an heir-loom. Knowledge of the virtue of certain remedies is handed down from sire to son and maintained a secret; thus producing specialists in the use of herbs, skins of reptiles, charms, amulets, superstitious and idolatrous practices. Regular medical education is unknown, yet every scholarly man is more or less a physician. The Chinese know nothing of hygiene. Filth and vermin encompass them as with a garment.

The London Missionary Society sent Robert Morrison, a practicing physician, to China in 1805. In 1829, Dr. College was stationed at Macao. The Scotchman Dr. James Henderson's medical work in Shanghai, is one of the most interesting on record. The American Board of Foreign Missions appointed the Rev. Peter Parker, M. D., a medical missionary in 1834. He opened an ophthalmic hospital in Canton, which was the forerunner of all subsequent hospitals.

In 1844, the Presbyterians founded a mission in Ningpoo, with Dr. D. Bethune McCartee, of this State, as medical missionary, who remained in China until 1872. He then removed to Japan for some years, and now has returned to this country. Dr. McCartee wrote me that he had never heard of a case of scarlet fever or diphtheria during his residence in China. He had never been called to

more than four or five obstetrical cases in all that time. He had sent preparations of ergot in cases of flooding, and only prescribed in women's diseases at second hand.

Restraint, "chains and cells in the houses of relatives," was the only treatment for the insane he had ever heard of.

The mortality of parturient women was large. "A female physician would, of course, have a great advantage among those of her own sex in China, over a male physician."

Another Presbyterian mission was established in Canton in 1854, with John G. Kerr as medical missionary. Owing to the peculiar social customs of the Chinese, and their views of propriety, men medical missionaries have done nothing comparatively for suffering women. Woman's medical work was begun in Peking in 1873 by Dr. S. Combs, sent by the Philadelphia Branch of the Woman's Foreign Missionary Society of the M. E. Church. Dr. Combs prosecuted her work in the midst of great difficulties, but with much success in winning the hearts of the Chinese women. During the first year, she prescribed for 374 cases, and 37 were treated in their own homes. In closing her report, she says: "I have treated with general success a sufficient number of cases to make me feel that the work is well begun."

A hospital building was completed in 1875, by which time she was able to do without an interpreter. In the annual report of 1876, I find, "the medical work in charge of Miss Combs, M. D., is eminently successful. She is kept exceedingly busy with out-door, as well as hospital practice." "Many would have been discouraged by the difficulties to be overcome in establishing medical work, but Miss Combs' love of her profession, her untiring zeal and her unwavering faith, have carried her triumphantly through the pioneer years of a medical missionary." "Medical work has won its way through her quick, persistent methods in this old heathen capital." "After nearly five years of efficient service, she moved to Kiukiang."

Dr. Combs was followed by Miss L. Howard, M. D., a graduate of Michigan University. She took charge of the hospital in July, 1877. In May, 1878, Dr. Howard wrote: "From July, 1877, to March, 1878, during these months dispensary patients numbered 1612, out-door patients 50, and 10 have occupied the wards. Among the out-patients I have found many in a very destitute condition, having neither food, fire, nor clothing."—"The people invariably treat me with respect, and seem grateful for the smallest favors."—

"About this time famine prevailed throughout North China, when many thousand natives died ; pestilence followed."—"A number of missionaries were seized with the malignant fevers, and died." Dr. Howard wrote: "There has been a great deal of sickness among the missionaries, and for a time I was the only physician in Peking. I did not fear the contagion, though it was terrible. We could hardly go on the streets without seeing the dead and dying, lying just where they happened to fall."—"The last three months have brought sad days to the North China mission." The report said, "Dr. Howard's courage never failed her in all these days of trial, when death was on every side, but her physical powers were greatly taxed." She reported "2015 day patients, 80 out-door patients, and 18 having occupied the wards for the entire year."

In the fall of 1878, medical work was suspended in Peking, by Dr. Howard being called to Tientsin, the seaport of the province, eighty miles distant by land and one hundred and twenty miles by water.

The way for this change was brought about by providential circumstances beyond her control. When Gen. Grant and his party were visiting in Tientsin, in June, 1878, they were entertained several times by the Viceroy, Li Hung Chang, the Governor-General of the province, next in authority to the Emperor, and the leading statesman in the Empire. His wife, Lady Li, gave an evening entertainment to the wives of the resident officials. A lady of the mission accompanied Mrs. Grant as interpreter. When a few weeks later Lady Li was very ill and given up to die by the native doctors, the Viceroy, being in sore distress at the prospect of losing his wife, in opposition to the prejudices and principles of the Chinese, yielded to the persuasions of the United States Consul (who was the private secretary of the Viceroy), and sent for the foreign physician of the city and the medical missionary of the London Missionary Society. These carried Lady Li safely through the immediate peril, but they, as men physicians, could not diagnose the case of a lady patient. Both doctors united in petitioning the Viceroy to send for Dr. Howard, and the possibility of saving his wife enabled him to set at naught all Chinese ceremonies. A courier was dispatched with a request to Dr. Howard to come, and a steam launch sent to meet her to hasten her arrival. Happily, the disease of Lady Li yielded to the medication of Dr. Howard ; and soon Lady Li learned not only to appreciate Dr. Howard's medical skill, but to feel for her a ten-

der regard. Strong inducements were held out to persuade Dr. Howard to remain in Tientsin. Apartments were fitted up in one of the temples of the city for a dispensary by the Viceroy, and Lady Li became responsible for its support.

Miss Howard's associate wrote: "We know not how much this is for China, but it looks like a big wedge in very near the throne."

Dr. Howard wrote, March 21, 1879: "I commenced work in the dispensary about the middle of October, 1878. Up to the present time, I have treated 310 patients in the temple, and visited 120 patients in their homes."—"I live about three miles from the temple, in the foreign settlement, where I have treated over 1,000 patients and have visited seventeen patients in their houses. We consider this the most important part of our work."—"I am called to the houses of the highest officials ; their prejudices are breaking down everywhere over the land."—"Patients come from the interior and take up their residence near the temple, that they may be treated."

Rev. H. H. Lowery wrote: "The importance of the present opening can scarcely be overestimated. Dr. Howard's attendance upon the Viceroy's wife has made an opportunity such as never occurred in China before, and if lost now, may never occur again. The homes of many of the best and most influential of the city are open to the visits of your physician."

Dr. Aker was sent to Dr. Howard's assistance in 1882. In the annual report for 1883 were found the following numbers:

Of patients in wards	92
Of out-door patients	903
Of Missionary Dispensary	8,338
Perscriptions given	29,657

FOOCHOW.

In October, 1874, Miss Sigourney Trask, M. D., of Spring Creek, Pa., a graduate of "The Woman's Medical College in Philadelphia," was sent to Foochow by the New York branch of the Woman's Foreign Missionary Society of the M. E. Church. The number of patients treated the first year was 554, and 36 surgical operations. In April, 1877, a commodious, well-arranged hospital was ready for use. The first patient registered in it was a woman of 28 years, who had not walked erect for five years, on account of an injury to her knee. This resulted in ankylosis, with flexion at nearly a right angle. Dr. Trask made a resection, the limb was straightened, a good recovery made, and in three months the woman returned to her home, 60 miles from Foochow.

A little girl of 15 years had both legs ampu-

tated below the knees successfully. The mother of this girl's betrothed husband was greatly disturbed by her recovery. *

A pretty, bright young woman with bound feet, having a terribly ulcerated leg, was improving so that Dr. Trask hoped amputation would not be necessary.

A large tumor having been removed from the back of a woman, her husband said: "I had made offerings to many gods, but all to no good for my wife."

Concerning another who had her right arm amputated, Dr. Trask said, "I have but little hope for her."—"I do not think her friends will mourn very much, but rather rejoice."

In 1873, Dr. Trask wrote, "We have had almost 20,000 deaths of natives here in two weeks from cholera. It is a most malignant type."—"During the last quarter I have had 267 dispensary patients, and over 500 prescriptions have been made." The whole number of out-patients registered since 1877 is 1,206. Number of patients admitted into the wards of the hospital was 76.

In 1878, Dr. Julia A. Sparr, a graduate of Michigan University, was sent to reinforce Dr. Trask. Seven years ago Dr. Trask received, under instruction, the first female medical student in Foochow—the first ever in China. Since then five others have been received—six now being under instruction. Letters have been received by the society, asking that at least one of these, Hu Keng Eng, of whose ability, aspirations, and devotion, Dr. Trask speaks in the highest terms, should be brought to this country to remain ten years, if necessary, in order that she may go back qualified to lift the womanhood of China to a higher plane, and there to superintend our medical work; and this young student herself sends an earnest petition to be brought to America. "Shades of conservatism and Confucianism!"

Dr. Catherine Cory was added to the medical staff in Foochow in 1883.

In the annual report of the mission for 1883, I learn that woman's medical work grows steadily in interest and favor in Tientsin, as seen in the following table:

	<i>Patients.</i>	<i>Surgical Operations.</i>	<i>Deaths.</i>
Hospital Dispensary . . .	1,051	66	—
East Street " . . .	1,644	134	—
Bedside	262	60	—
House	58	26	2
	3,015	286	2

We gather from the annual report of 1883 of

the Presbyterian Board of Foreign Missions, that in Canton "another hopeful feature here is that it is reaching the women."—"Three women from the school have commenced Christian work, and one has entered upon the study of medicine."—"The hospital work, under Dr. John G. Kerr, has been greatly prospered. He has had 19,199 out-patients, 1,182 in-patients, and has performed 963 surgical operations. During a part of the year, Miss Mary E. Niles, M. D., of the Nankin Mission, was under his special instruction. Miss Butler is studying medicine, and several natives also have formed a class."

You will remember, Dr. Kerr went to Canton in 1854. Almost a generation has passed before "reaching the women." We are happy to know that the men medical missionaries have welcomed cordially the women physicians to their stations. But I have not noticed any other doctor than Dr. Kerr taking a newly-arrived woman medical missionary under his "special inspection."

We learned upon inquiry of a member of the Baptist Mission in Swatow, nearly in the same latitude, but a little east of Canton, as to the frequency of infanticide, that she had known:

100 mothers who had destroyed 158 female children.

40 mothers who had destroyed 78 female children.

6 mothers who had destroyed 11 female children.

When the mother does not strangle or smother her child by holding a cloth over its face, or by filling its nostrils and mouth with cotton saturated with incense, the child is wrapped in matting and carried by the father and thrown into the river, or into the little window of a walled pit prepared for the reception of female children, where lime is thrown over them. No one asks how the child came to its death. Boys are never destroyed. "A husband reviles or hates his wife if she does not bear sons, and may be legally divorced."

Miss Carrie Daniels, M. D., was sent to Swatow by the Woman's Baptist Foreign Missionary Society recently, and is laying the foundation for woman's medical work.

Dr. Virginia C. Murdock, a graduate of Michigan University, under the auspices of "The American Board of Commissioners for Foreign Missions," in Kalgan, on the mountains, answered my questions fully, but her letter was received too late to allow of more than a few quotations. She says infanticide "is not practiced to any extent."

The death of sons is a sore affliction, that of

daughters a good riddance. Small-pox is considered a regular disease of childhood. A son who has not been vaccinated is not counted as having a lease of life that can be depended on. None would think of having a girl vaccinated. If a cherished son is sick, a doctor is called, but with girls, it is the "survival of the fittest." Cholera infantum is very frequent and fatal. If a mother cannot nurse her child, a wet-nurse is hired. No other way to raise children is attempted. People do not seem to have the patience to care for their sick babies. Burial of the dead is general, but dead female children are often wrapped in a mat and thrown into the street at night, so that dogs may tear them to pieces, hoping that thus their little spirits will be liberated and come back to the parents as sons.

Chinese midwives are quite efficient ordinarily, but in unusual presentations and flooding their arts are at an end. Forceps are not permitted to be used in that locality. Dr. Murdock had been called in a case of post-partum hemorrhage, when she found the woman fainting, but held up by the hair of the head, it being dragged upward by the husband and brother taking turns as they became fatigued. No advice or inducement could be made to them to let go of her hair and allow her to lie down for an hour or two. She lived through it, but, as they thought, only because they adhered to their well-known theories.

A lying-in woman must not leave the house for forty days after her delivery, and must live on slop food all the time. Amenorrhœa was the most frequent disturbance of the menstrual function. Coughs, bronchial and asthmatic, with shortness of breath, very frequent. Dyspepsia universal. "Worms! worms! to be treated for round worms is everybody's fate." Skin diseases and ulcers of various sorts are common. Rheumatism, acute and chronic, not as frequent as might be expected, as the natives wear cotton hose and cotton shoes the whole year, and as their houses have brick floors.

Thirty-six women medical missionaries have been graduated, as follows:

In the Woman's Medical College of Chicago . . .	4
" Michigan University	5
" Woman's Medical College of the New York Infirmary	6
" Woman's Medical College of Penna.	20
Homeopathic	1

The W. F. M. S. of the M. E. Church have sent to India 7; to China 10; to Japan 2.

The W. F. M. S. of the Presbyterian Church have sent to India 2; to China 3.

The W. F. M. S. of the American Board of Com-

missioners of Foreign Missions have sent to India 2; to China 1.

The W. F. M. S. of the Baptist Church have sent to Burmah 2; to China 1.

The W. F. M. S. of the Lutheran Church have sent to Burmah 1.

There are 8 graduates of the Woman's Medical College of Pennsylvania under appointment:

One for Damascus, by the Episcopal Church.

Five for China: 1 by the Episcopal Board, 1 by the Methodist Church South, 1 by the Baptist Church South, and 2 by the Presbyterian Board.

One not determined whether India or China, and one not determined whether Burmah or China.

There are 8 under-graduate missionaries in the class in the Woman's Medical College of Pennsylvania.

As business men judge of the plausibility of a projected scheme by the amount of money that can be raised for its advancement, I thought it might be satisfactory to know what amount these Woman's Foreign Missionary Societies have collected during 1883. I have had access to the treasurers' reports of but four societies, from which I copy the following:

Woman's Baptist Foreign Missionary Society for 1883	\$23,546.70
Woman's Foreign Missionary Union for 1883	53,831.64
Woman's Foreign Missionary Society of the M. E. Church	167,037.50
Woman's Foreign Missionary Society of the Presbyterian Church	169,587.86

Joseph Cook, who has a most comprehensive knowledge of the subject of missions, tells us, "There are three hundred millions of women now on this planet who have only the Buddhist's hope of being born again as men, instead of toads or snakes. There are eighty millions of women in Moslem harems. There are uncounted millions of men, women and children growing up in the most degraded superstitions, and suffering in mind, body, and estate from inherited pagan customs."—"What can be done to help these millions?"—"In China there is not an ordained missionary to-day for a million of people."

In view of these almost stupendous numbers, the work of these Women's Foreign Missionary Societies is but as "playing at missions," and the work of women physicians in Asia as "throwing one pebble into the great ocean of missionary work."

—Doctor—"There, get that prescription filled, and take a tablespoonful three times a day before meals." Pauper patient—"But, doctor, I don't get but one meal in two days."—*Texas Siftings*.

THE TIME REQUIRED BY THE BLOOD FOR
MAKING ONE COMPLETE CIRCUIT
OF THE BODY.*

BY ROBERT MEADE SMITH, M. D.,
Professor of Comparative Physiology, University of Penn-
sylvania.

In a paper published in the *Philadelphia Medical Times* for January 26, 1884, I gave an account of a new method which I had employed to measure the amount of blood thrown out of the ventricles at each contraction, and to determine the time required by the blood for making one complete circuit of the body. I there had occasion to criticise the method which has heretofore been employed to answer this latter question, and to point out some of its defects. I have recently been studying this subject from another point of view, and have obtained some results which strengthen the position taken in the article referred to.

It will be remembered that the method which has been employed for this purpose, the infusion method of Hering (*Zeitschrift. für Phys.*, Bd. iii. and v., and *Arch. für Phys. Heilkunde*, 1853, p. 112), consists in injecting into one jugular vein towards the heart a solution of some salt whose presence in the blood can be readily recognized by chemical tests, and in finding how soon after the injection the salt appears in the blood coming from the head in the corresponding vein on the opposite side of the neck.

When thus injected, to reach the peripheral portion of the opposite jugular vein, the salt must evidently have passed into the right heart, through the capillaries of the lungs, into the left heart, through the carotids or vertebral arteries to the head, and through the capillaries of the head or face to the jugular vein; or, in other words, must have passed through two capillary networks with their arteries and veins. It must, therefore, have completed an entire circulatory revolution. But to conclude that the time elapsing after the introduction of the salt into one jugular vein before it is found in the blood coming from the head in the opposite vein is the time required for one molecule of blood to pass from one of these points to the other, it must in the first place be admitted that the salt has been carried mechanically by the blood, without diffusing through it, with the same velocity as the blood itself; and in the second place, to enable the formation of any opinion as to how often the entire mass of blood passes through the heart, it must be admitted that the velocity thus determined by the infusion method is the mean velocity of the

blood mass. To show that both of these assumptions are unwarrantable is the object of the present communication.

I. *The Element of Diffusion in Hering's Method.*—Poisseeuille (*Ann. d. Sciences Nat.*, 1843, ii. ser. t. xix., p. 30) was the first, and as far as I know has been the only one to offer any experimental proof as to the falsity of the belief that the potassium salt was carried mechanically, as would be an inert body, by the blood. He repeated Hering's experiments on the horse, and was able to confirm his statement as to the time elapsing after the injection of the solution of potassium ferrocyanide before it appeared in the jugular vein of the opposite side; but he further found that this time was different for different substances, and was even modified by the presence of other substances when injected with the potassium ferrocyanide. Thus, while the time required for the circulation of the potassium ferrocyanide was *twenty-eight* seconds in the horse, when a little alcohol, in quantity insufficient to have any appreciable effect on the pulse and blood pressure as measured with the hæmadynamometer, was injected with the potash salt, the time of circulation was lengthened to *forty-five* seconds. Or, when potassium nitrate or ammonium acetate was administered under similar circumstances, the duration of circulation was reduced to *eighteen* or *twenty* seconds. In other words, he found that in the living body the rapidity of circulation of substances mixed with the blood agreed with the rapidity of flow of the same substances through dead capillaries or even through glass tubes.

It is, moreover, well known that if two fluids capable of mixing are brought into contact, they will diffuse into each other with a considerable degree of rapidity, even when the mass of the liquid is at rest, or when there is a great difference in the relative volumes of the fluids; while if one fluid is poured into another with which it is miscible, or if agitated after the two fluids are brought into contact, diffusion is almost instantaneous. And as some force is always employed in injecting the salt solution into the vein, the mixture of this solution with the blood will be promoted, while the motion of the blood renders the conditions still more favorable for diffusion.

The assumption is, therefore, a fair one, until subjected to experimental disproof, that the element of diffusion forms a considerable item in the rapidity with which solutions of salts complete the circuit of the body. As far as I know, however, no such proof has ever been advanced, and the direct experiments which I have made on this

*Read before the College of Physicians of Philadelphia.

subject serve rather to confirm than to disprove this assumption.

It is evident that if any particulate, inert substance, small enough to pass through the capillary networks, and capable of ready recognition, could be injected into the blood, there could be no question as to the element of diffusion in the time required for such a substance to complete the circuit of the body; its velocity of movement must be the velocity of the current in which it moves; and if more time is required for the circulation of such a body than for the salt solution, it will be evident that some force other than the propulsion of the blood is concerned in the movement of the salt. These conditions I believe to be filled in employing pigeon's blood as the body whose transit is measured.

The red blood corpuscles of the pigeon have a short diameter smaller than the diameter of mammalian blood disks; and as all red blood corpuscles pass edgewise, and oval corpuscles (as in the frog) pass endwise in the centre of the blood stream, it is probable that the pigeon's corpuscles will circulate in mammalian blood-vessels with their long diameter in the axis of most rapid movement. They therefore agree with the first requisite as to size.

In the second place, they are oval and nucleated, and so form such a strong contrast to mammalian blood disks that a single pigeon's corpuscle in a drop of mammalian blood can be found under the microscope with the greatest readiness.

It might at first be seen, however, that pigeon's blood injected into the vessels of a mammal is by no means an inert substance. It was proved in the earlier operations of transfusion that the blood of one species of animal is a direct poison for other species. When the blood, whether defibrinated or not, of one group of mammals is injected into the vessels of another of the same class, but of different species, the corpuscles of the injected blood rapidly disappear, the plasma becoming red from the liberated hæmoglobin, which, when large quantities of blood are injected, may pass off through the kidneys, causing hæmoglobinuria, or even into the mucous and serous secretions; while at the same time the corpuscles of the animal receiving the injection, if they are themselves soluble in the injected blood, break down, and, as a consequence, convulsions and death through asphyxia may result.

The resistance offered to these phenomena differs in different groups of animals; thus, the dog, of all animals, is least liable to dangerous symptoms following the injection of blood from a

different species. There is still another complication to be noted. Before the corpuscles are dissolved they tend to run together into heaps and so cause emboli, while again the liberation of hæmoglobin is likely to cause thrombosis.

It would seem from the above that pigeon's blood, which was also found by Bischoff to provoke analogous symptoms when injected into mammals, is by no means an inert substance, and is therefore entirely unfitted for the use I have made of it. Such is not, however, the case. The production of the symptoms mentioned above is a question of minutes; the duration of the circulation one of seconds; and I have found by direct experiment, as will be shown later, that the circulation is completed before disorganization commences.

There is one difficulty, however, that must be guarded against. The solution of the pigeon's corpuscles occurs not only in the vessels of the dog, the animal on which most of my experiments were made, but also after blood had been drawn and exposed to the air. Therefore, if the corpuscles are not sought for within a very short time after the withdrawal of the blood, they will only be found with great difficulty, and sometimes not at all, though it may be that their presence in the same portion of blood was proved only a few minutes before. To avoid error from this cause, Dr. Gray, the Assistant Demonstrator of Histology in the University, kindly examined the blood for me the instant that the collection was made, and before alteration had commenced. Such a procedure is not, however, absolutely necessary, as the first change in the corpuscles is their loss of hæmoglobin and consequent transparency, while the cell wall disappears still later, and the nucleus remains unchanged for some time. If, therefore, a little aniline red is added to the drop of blood under examination, pigeon's corpuscles, otherwise almost invisible, can be readily recognized.

Method of Experiment.—Two pigeons were killed by decapitation immediately before the experiment, and their blood collected in a dry porcelain dish and thoroughly defibrinated by whipping with glass rods; the blood was then filtered through a fine linen cloth moistened with half per cent. salt solution (water was avoided so as to preserve corpuscles unaltered).

The animal to be experimented on was then tied and etherized, and glass canulæ, of the same calibre as the vessels, were inserted into the external jugular veins, in the left directed towards the heart, and in the right towards the periphery, the flow of blood being prevented by spring clips.

A canula was then inserted into the femoral artery, and connected with a mercurial manometer writing on the kymographion.

The canula in the right external jugular vein was connected by means of a piece of rubber tubing about 4 centimeters long with a glass stopcock by which the outflow of blood could be regulated to about the amount normally passing through the vein.

The apparatus for collecting the blood and for noting the time of each collection consisted of a horizontal glass disk 31 centimeters in diameter, which could be uniformly rotated by clock-work at any desired speed. Twenty-four watch-glasses, each about two cm. in diameter, were fastened by sealing-wax around the edge of the disk, and the apparatus was so arranged that as the disk rotated, the centre of each watch-glass passed under the stopcock connected with the right jugular vein.

The time was recorded in the following way: The entire disk, with the exception of the border on which the glasses were fastened, was covered with a layer of lampblack, and an electro-magnetic lever so arranged that as the disk revolved it would describe a concentric circle on the smoked surface. This electro-magnet, with a similar lever writing on the drum of the kymographion, was included in an electric circuit broken every second by a second's pendulum. Each interruption of the circuit, therefore, made a mark simultaneously on the revolving disk and on the moving paper of the kymographion. The apparatus was further so arranged that a single movement started the revolving disk, and at the same time made a mark on the already revolving drum of the kymographion. The orifice of outflow from the stopcock, and the time lever, were on the same radius of the disk.

A syringe containing 10 c.c. was then filled with the defibrinated pigeon's blood and bound in the canula, previously filled with the same blood, in the left external jugular. After all connections were made, the kymographion was started and allowed to revolve for twenty or thirty seconds before making the injection, so as to get a normal pulse and pressure curve. The clip was then removed from the right jugular vein, and as soon as the blood commenced to flow from the glass stopcock, the clip was removed from the left jugular, the injection made, and the disk started simultaneously—the instant of starting the disk being also automatically recorded below the pulse line on the kymographion.

When all the cups were filled with blood the

disk was stopped, and the blood instantly examined microscopically for the presence of pigeon's corpuscles. When it was determined in which glass they first appeared, it was only necessary to count the number of breaks in the time line on the disk from this glass to the start to determine how many seconds were required for the pigeon's corpuscles to pass from the left jugular vein to the right—while by laying off on the kymographion tracing the same number of seconds from the starting of the disk, the number of pulsations in that period was readily determined, and also whether the injection produced any disturbance of circulation.

(To be Continued.)

REPORT OF A CASE OF SUCCESSFUL REMOVAL OF THE SPLEEN IN A DOG.*

BY DR. W. J. ASDALE,
Of Pittsburgh, Pa.

To those interested in cases of removal of the spleen, the following case might prove of interest:

In June, 1875, Dr. W. J. Asdale, assisted by Dr. J. J. Todd (since deceased) and Mr. C. J. O'Brien, then a medical student and now a practicing attorney in Pittsburgh, removed the spleen from a one-year-old black poodle dog, weight estimated at fifteen pounds. The animal being put under the influence of ether, an incision three inches in length was made in the median line over the epigastric region; by pressing aside the stomach and intestines, the spleen was easily brought into view. It was removed entire, by detaching it gently from the surrounding parts, leaving only a narrow pedicle, which was then pierced in the centre and silk ligatures thrown around both halves. The pedicle was then severed, and the ligatures cut off short and allowed to remain in the wound. The parts were then thoroughly cleansed, and the abdominal incision closed with six silver sutures. The dog was then permitted to care for himself, being supplied with a very limited quantity of milk. In two weeks, the edges of the wound having united perfectly, the silver sutures were removed. This dog remained around Dr. Asdale's house as a house-pet for nine years. He died in January, 1884. In this case the operation did not seem to change his disposition: he remained good-natured and thrifty. He developed rapidly, his weight at the time of his death being estimated at from twenty-five to thirty pounds. He was a good, active watch-dog, a good

* Reported by Wm. H. Mercur, M. D., Resident Physician West Pennsylvania Hospital, Pittsburgh, Pa.

feeder, never morose or sullen. The greater part of the time he was well nourished; his skin was clean, and his hair smooth and glossy.

He died suddenly, after being exposed to severe cold. The post-mortem, at which I was present, was made a few hours after death. The body was in good condition, and not emaciated. The only pathological lesion found was a severe enteritis affecting the lower part of the small intestines, from which, in all probability, the dog died. His lungs, heart, kidneys, and all his other organs, were perfectly normal. There was not the slightest trace of the spleen, nothing to denote its former locality, no remains of a pedicle, nor anything to show that nature had made the slightest attempt at restitution; its origin was entirely obliterated.

HOSPITAL REPORTS.

BELLEVUE HOSPITAL, NEW YORK.

REPORTS BY J. H. WOODWARD, M. D.

House Surgeon.

Burns and Scalds.

In this report I propose to consider the subject of the management of burns and scalds. They are always injuries which subject the patient to considerable pain, and not infrequently they are severe enough to endanger his life. If they be managed according to certain methods, not only do they become cases which are disgusting to the attendants, but they are rendered still more dangerous to the patient. There are other methods of treatment, however, which remove the disagreeable features referred to, and which, above all, diminish the danger to life and hasten the healing process. It will be the object of this article to describe, as briefly as possible, the management of these cases as it is followed in this institution at the present time.

Burns were classified by Dupuytren according to the depth of the lesion, and he divided them into cases presenting six degrees of severity. In burns of the first degree, there is only inflammation of the skin. In cases of the second degree, the epidermis is detached and blebs of various sizes are formed. In burns of the third degree, the cuticle and a portion only of the true skin are destroyed. In cases of the fourth degree, the lesion extends through the true skin. And in cases of the fifth and sixth degrees, the burn involves muscles, tendons, nerve-trunks, blood-vessels, and bones.

The cases most frequently met in this institution may be classified under the second and third divisions. Burns of the first and fourth degrees are seen occasionally. Cases of burns extending to the fifth and sixth degrees have not entered this institution during the past two years. And for the reason that such cases have not been treated here during your reporter's residence in

the hospital, the following remarks must not be regarded as relating to such cases.

The constitutional symptoms present in any case will depend upon the power of endurance of the patient and, speaking generally, upon the extent of surface burned. Pain is a constant symptom, and seems to be most intense in cases of the second degree. There is generally some shock at the outset, and it seems to be prolonged by the pain. As a rule, the quantity of urine excreted is diminished from the outset. In many cases during the first week or two, that may become a very serious symptom. In a considerable number of cases, albumen may be found in the urine after the first twenty-four hours, and, in some cases, blood may also be found there. During the first week the temperature may be elevated to 100°-101°. In more serious cases, the temperature will range from 100° to 103° for five or six days. The heart generally requires stimulation. The patient will emaciate very rapidly, even when the burn appears to be of moderate severity only.

When the burn affects a large area of skin, whether it be of the first, second, or of any degree, the prognosis must be very guarded. The presence of albumen or blood, or both, in the urine should be regarded as a grave symptom. Of all the cases of death from burns that have come under my observation, a certain number have died of shock within forty-eight hours. But a larger number have perished at a later period. Those cases have perished after presenting the following symptoms: the urine was diminished very much in quantity and generally contained albumen. The skin was dry and the bowels constipated. The patient became delirious, and after several days he became stupid. The pulse was rapid and feeble. The temperature was above 100° for several days, and, within twenty-four hours of the patient's death, began to rise until some of these cases died with a temperature of 108°. There was failure of the peripheral circulation in the extremities a number of hours before death.

Only one case presented any symptoms of duodenal trouble. And but one instance of ulceration in the duodenum has been found in the autopsy room. That case was one of "frost-bite" of the fingers of both hands.

Having briefly referred to a number of the most important symptoms, we will consider the constitutional treatment. For the pain, morphine should be given hypodermically in sufficient amount to make the patient comfortable. And *tr. digitalis* or whisky may be given hypodermically for the feeble heart-action during the period of shock. As soon as the patient has rallied and can take substances by the mouth, he is given *inf. digitalis*, $\mathfrak{ss}$.; *potassii acetatis*, gr. xv., every three hours night and day. He is put upon a milk diet exclusively. Under that course of treatment, the patients do better than if they are not managed with the object of relieving the kidneys. As soon as the patient is strong enough, a cathartic is administered. And should any suspicion of uræmic poisoning become justifiable, diaphoretics are added to the list of drugs. In one such case I have administered nitrate of pilocarpine, hypodermically, in sufficient amount to excite the action of the skin. The patient improved very markedly after that drug had been administered.

The temperature seldom requires treatment. Although the fever will continue for a number of days, and, although the patient is in poor condition to endure a high temperature, the experience of this hospital seems to be in favor of permitting the fever to run its own course. Antipyretic doses of quinine and cold baths injure a certain number of these patients much more than the febrile movement. Should the temperature begin to rise after remaining pretty steadily about 102 for a number of days, in many cases it would be better to attempt to establish the peripheral circulation in the extremities than to give quinine or a bath. In such cases, the temperature may rise because the circulation is poor in the skin. If such be the case, it is ruinous to give large doses of quinine. Turpentine stupes or flaxseed and mustard poultices applied to the feet fulfil the indications pretty well. For all temperatures in cases of burns it is good practice to avoid the use of all antipyretic agents. In the majority of cases good tonic treatment should be begun early.

For the treatment of the burn itself there are two very popular remedies. They are carron oil and vaseline. But they should be discarded entirely in these cases. Under their use there is profuse suppuration, the room is filled with an odor that is very disgusting, the dressing must be renewed frequently, and the lesion does not heal rapidly. Iodoform ointment (3j. to 3j.) is used in hospital practice often enough, but it is unsuited to the requirements of private work. The odor of the drug is not the sole objection to its use in these cases, however; for it is not difficult to poison the patient with iodoform, when the ointment is applied to deep or extensive burns. A number of cases of such poisoning have occurred in this hospital; but there have been no fatal results thus far.

The requisites of a satisfactory dressing for cases of burns may be enumerated as follows: It should be comfortable to the patient, diminish secretion from the affected part, require to be renewed only at long intervals, and it should promote healing. A large variety of dressings have been tried here, and now the general opinion is fixed upon certain methods, which will be given as briefly as possible.

Suppose that the lesion is one of the second degree. The affected region is covered with blebs of various sizes. These blebs are cut open with a scissors and evacuated. The detached epidermis is cut away carefully. Leaving the epidermis *in situ* after evacuation of the blebs does not seem to offer any advantages, and sometimes such practice retards the healing process. While these manipulations are in progress, the affected member should be irrigated with some antiseptic solution. Bichloride of mercury dissolved in water (1-2000) has been used here very extensively for this purpose. It is too corrosive in that strength, and causes many patients to suffer indescribable agony. I have seen a patient in convulsions on account of the pain, in spite of large hypodermics of Magendie's solution. There are many patients, however, who will not complain of the corrosive mercury. Used upon extensive burned surfaces, carbolic solutions may give rise to poisoning, which should, of course, be avoided in such cases above all others. And, furthermore, they are

irritant, and give rise to a large secretion of serum. Tursch's antiseptic fluid, which contains boracic acid five parts, salicylic acid one part, to water five hundred parts, is not very irritant, and is perfectly effective. It is the best solution for this use. The burned surface is irrigated with that solution and washed gently with sponges. Having thoroughly cleansed and having rendered the burned region as aseptic as possible, we dust upon it a layer of subnitrate of bismuth thick enough to thoroughly protect the part. On this four or five thicknesses of carbolized or bichloride gauze should be wrapped gently. Over all some antiseptic cotton is placed in a thick layer, and bound on gently with a bandage. This dressing will remain perfectly sweet for a week or two. Should serum come through it after a day or two, we cover the discharge with more cotton and a bandage. The part is examined after a week or two, according to the size of the burned district. Usually at the end of one week the burn is examined and found healed throughout. Should a second or a third dressing be required, it is applied under the same rules as the first. It is possible to cite a large number of such cases, and give the details of their management, but it seems to me unnecessary to do so.

Burns of the second degree about the face are very satisfactorily treated with a saturated solution of bicarbonate of soda in water. That is applied by making a mask of sheet-lint for the burned district, which mask is kept constantly wet with the solution. The blebs and epidermis are treated in these cases as in the others. Bismuth powder answers the purpose here very well indeed.

Burns of the third and fourth degrees require another sort of dressing. In these cases the bismuth dressing will become very foul smelling after three or four days. The discharge is much greater than in the former set of cases, and the bismuth salt is not antiseptic, so that the discharges are apt to undergo putrefaction, unless the dressing is renewed every second or third day. Cases of burns of the third and fourth degrees, if extensive, present a great variety of difficulties, and they often require a great deal of skill and patience on the part of the physician for their proper management. It is but to render them aseptic at the onset and to keep them so until they have healed. The Tiersch antiseptic fluid is efficient, and should be chosen for irrigating and washing the parts. The burn should be cleansed thoroughly of sloughs and other dead tissue. Then the dressing may be applied, and it should be of such a nature that it may remain undisturbed for a week or two. Boracic acid crystals may be powdered upon the lesion; or boracic ointment (3j. to 3j.) may be used spread upon antiseptic gauze. If boracic acid crystals are selected, then the lesion is thickly covered with them. Disinfected rubber tissue should then be applied in strips over the acid, and the antiseptic gauze and cotton dressing applied as in cases of the second degree. Granulation is favored and promoted by this treatment, and cicatrization goes on satisfactorily. These large ulcerating surfaces should be skin-grafted as soon as the granulations are in the proper condition for it. After the grafts have been placed upon the ulcer, the boracic acid

may be dusted upon the part and the dressing made as before. Instead of boracic acid or the boracic ointment, a powder composed of equal parts of subnitrate of bisnuth and iodoform may be used to accomplish the objects in view. I am inclined to think that this powder promotes healing more satisfactorily than any other dressing I have seen used in these cases. There is very little discharge, and cicatrization proceeds very rapidly.

In any case of deep and extensive burns, considerable time must elapse before healing is complete. The patient is confined to bed, and that alone is sufficient to lower his vitality. It is very necessary, therefore, that the discharges should be reduced to a minimum quantity. For the attainment of the objects in view, the closed dressings which I have described in this paper are the best that have been used in this hospital.

By the employment of them the mortality has been diminished, and the period of healing very much shortened.

MEDICAL SOCIETIES.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

(Continued from page 655.)

Probably amongst the palsies may be considered the disturbances of the renal functions, which are rarely met with in cerebral syphilis, and which are probably usually dependent upon the specific exudation pressing upon the vasomotor centres in the medulla. Fournier speaks of having notes of six cases in which polyuria with its accompaniment, polydipsia, was present, and details a case in which the specific growth was found in the floor of the fourth ventricle. Cases have been reported in which true saccharine diabetes has been present (Consult. Servantié, *Des rapports du Diabète et de la Syphilis*. Paris Thèse, 1876), and I can add to these an observation of my own. The symptoms, which occurred in a man of middle age with a distinct specific history, were headache, nearly complete hemiplegia, and mental failure, associated with the passage of comparatively small quantities of a urine so highly saccharine as to be really a syrup. Under the influence of the iodide of potassium the sugar in a few weeks disappeared from the urine.

Epilepsy.—Epileptic attacks are a very common symptom of meningeal syphilis, and are of great diagnostic value. The occurrence in an adult of an epileptic attack, or of an apoplectic fit, or of a hemiplegia after history of intense and protracted headache, should always excite grave suspicion.

Before I read Prof. Fournier's work on Nervous Syphilis, I taught that an epilepsy appearing after thirty years of age was rarely, if ever, essential epilepsy, and unless alcoholism, uræmic poison, or other adequate cause could be found, was in nine cases out of ten specific; and I therefore quote with satisfaction Prof. Fournier's words: "L'épilepsie vraie, ne fait jamais son premier début à l'âge adulte, à l'âge mûr. Si un homme adulte, au dessus de 30, 35 à 40 ans, vient à être pris pour la première fois d'une crise épileptique, et cela dans la cours d'une bonne santé apparente, il y a,

je vous le répète, lui, ou neuf chances sur dix pour que cette épilepsie soit d'origine syphilitique."

Syphilitic epilepsy may occur either in the form of petit mal or of the haut mal, and in either case may take on the exact characters and sequence of phenomena which belong to the so-called idiopathic or essential epilepsy. The momentary loss of consciousness of petit mal will usually, however, be found to be associated with attacks in which, although voluntary power is suspended, memory recalls what has happened during the paroxysm; attacks, therefore, which simulate those of hysteria, and may lead to an error of diagnosis.

Even in the fully developed type of the convulsions, the aura is only rarely present. Its absence is not, however, of diagnostic value, because it is frequently not present in true essential epilepsy, and it may be pronounced in specific disease. It is said that when in an individual case the aura has once appeared, the same type or form of approach of the convulsion is thereafter rigidly adhered to. The aura is sometimes bizarre; a severe pain in the foot, a localized cramp, a peculiar sensation, indescribable and unreal in its feeling, may be the first warning of the attack.

In many, perhaps most cases of specific convulsions, instead of a paroxysm of essential epilepsy being closely simulated, the movements are in the onset or, more rarely, throughout the paroxysm, unilateral; indeed, they may be confined to one extremity. This restriction of movement has been held to be almost characteristic of syphilitic epilepsy; but it is not so. Whatever diagnostic significance such restriction of the convulsion has, is simply to indicate that the fit is due to a cortical organic lesion of some kind. Tumors, scleroses, and other organic lesions of the brain cortex, are as prone to cause unilateral or monoplegic epilepsy when they are not specific as when they are due to syphilis.

Sometimes an epilepsy, dependent upon a specific lesion implicating the brain cortex, may be replaced by a spasm which is more or less local and is not attended with any loss of consciousness. Thus, in a case now convalescent in the University Hospital, a man, aged about thirty-five, offered a history of repeated epileptic convulsions; but at the time of his entrance into the hospital, instead of epileptic attacks, there was a painful tic. The spasms, which were clonic, and occurred very many times a day—sometimes every five minutes—were very violent, and mostly confined to the left facial nerve distribution. The trigeminus was never affected, but in the severer paroxysms the left hypoglossal and spinal accessory nerves were profoundly implicated in all of their branches. Once, fatal asphyxia from recurrent laryngeal spasm of the glottis was apparently averted only by the free inhalation of the nitrite of amyl. The sole other symptom was headache, but the specific history was clear, and the effect of anti-syphilitic remedies rapid and pronounced.

Psychical Symptoms.—As already stated, apathy, somnolence, loss of memory, and general mental failure, are the most frequent and characteristic mental symptoms of meningeal syphilis; but, as will be shown in the next chapter, syphilis is able to produce almost any form of insanity, and there-

fore mania, melancholia, erotic mania, delirium of grandeur, etc., etc., may develop along with the ordinary manifestation of cerebral syphilis, or may come on during an attack which has hitherto produced only the usual symptoms. Without attempting any exhaustive citation of cases, the following may be alluded to:—

Dr. A. Erlenmeyer reports (*Die leutischen Psychosen*) a case in which an attack of violent headache and vomiting was followed by paralysis of the right arm and paresis of the left leg, with some mental depression; a little later the patient suddenly became very cheerful, and shortly afterwards manifested very distinctly delirium of grandeur with failure of memory. Dr. Batty Luke reports (*Journ. Ment. Sci.*, Jan. 1874, p. 560) a case in which with aphasia, muscular wasting, strabismus, and various palsies, there were delusions and hallucinations.

In the same journal, April, 1869, Dr. S. D. Williams reports a case in which there were paroxysmal violent attacks of frontal headache. The woman was very dirty in her habits, only ate when fed, and existed in a state of hypochondriacal melancholy.

M. Leiderdorf details a case with headache, partial hemiplegia, great psychical disturbance, irritability, change of character, marked delirium of grandeur, epileptic attacks, and finally dementia, eventually cured with iodide of potassium. (*Medizin. Jahrbücher*, xx, 1864, p. 114. Several cases illustrating different forms of insanity are reported by Dr. N. Manassurow. (*Die Tertiäre Syphilis*, Wein., 1877.)

That the attacks of syphilitic insanity, like the palsies of syphilis, may at times be temporary and fugitive, is shown by a curious case reported by Dr. H. Hayes Newington (*Journ. Ment. Sci.*, London, xix, 555), in which along with headache, failure of memory, and ptosis in a syphilitic person, there was a brief paroxysm of noisy insanity.

DISEASES OF BRAIN SUBSTANCE.—The psychical symptoms which are produced by syphilis are often very pronounced in cases in which the paralysis, headache, epilepsy, and other palpable manifestations, show the presence of gross brain lesions. In the study of syphilitic disease of the brain membranes, sufficient has been said in regard to these psychical disturbances; but the problem which now offers itself for solution is as to the existence or non-existence of syphilitic insanity, *i. e.*, of an insanity produced by specific contagion, without the obvious presence of gummatous disease of the brain membranes. Very few alienists recognize the existence of a distinct affection entitled to be called syphilitic insanity, and there are some who deny that insanity is ever directly caused by syphilis. It is certain that insanity often occurs in the syphilitic, but syphilis is abundantly joined with alcoholism, poverty, mental distress, physical ruin, and various depressing emotions and conditions which are well known to be active exciting causes of mental disorder. It may well be that syphilis is in such way an indirect cause of an insanity, which under the circumstances could not be properly styled syphilitic.

If there be disease of the brain cortex produced directly by syphilis, of course such disease must give rise to mental disorders, and, if the lesion be situated in such a way as to affect the psychic and

avoid the motor regions of the brain, it will produce mental disorder without paralysis, *i. e.*, a true insanity; again, if such brain disease be widespread, involving the whole cortex, it will cause a progressive mental disorder, accompanied by gradual loss of power in all parts of the body and ending in dementia with general paralysis; or, in other words, it will produce an affection more or less closely resembling the so-called General Paralysis of the Insane, or Dementia Paralytica.

As a man having syphilis may have a disease which is not directly due to the syphilis, when a syphilitic person has any disorder there is only one positive way of determining how far said disorder is specific, namely, by studying its amenability to anti-syphilitic treatment. In approaching the question whether a lesion found after death is specific or not, of course such a therapeutic test as that just given is inapplicable. We can only study as to the coexistence of the lesion in consideration with other lesions known to be specific. Such coexistence of course does not absolutely prove the specific nature of a nutritive change, but renders such nature exceedingly probable.

What has just been said foreshadows the method in which the subject in hand is to be here examined, and the present chapter naturally divides itself into two sections: the first considering the coexistence of anatomical alterations occurring in the cerebral substance with syphilitic affections of the brain membranes or blood-vessels, the second being a clinical study of syphilitic insanity.

In looking over literature I have found the following cases in which a cerebral sclerotic affection coincided with a gummatous disease of the membrane. Gross and Lancereaux (*Affect. Nerv. Syphilis*, 1861, p. 245) report a case having a clear syphilitic history, in which the dura mater was adherent to the skull. The pia mater was not adherent. Beneath, upon the vault of the brain, was a gelatinous exudation. The upper cerebral substance was indurated, and pronounced by M. Robin, after microscopic examination, to be sclerosed. At the base of the brain were very atheromatous arteries and spots of marked softening.

Dr. Jos. J. Brown (*Journ. Ment. Sci.*, July, 1875, p. 271) reports a case in which the symptoms were melancholia, excessive irritability, violent outbursts of temper, very positive delusions, disordered gait, ending in dementia. At the autopsy, which was very exhaustive, extensive syphilitic disease of the vessels of the brain and spinal cord was found. The pia mater was not adherent to the brain. The convolutions, particularly of the frontal and parietal lobes, were atrophied with very wide sulci, filled with bloody serum. The neuroglia of these convolutions was much increased, and "appeared to be more molecular than normal, the cells were degenerated and in many places had disappeared, their places being only occupied by some granules." These changes were most marked in the frontal convolutions.

H. Schule reports (*Allgem. Zeitschrift f. Psychiatrie*, xxviii., 1871–2,) a very carefully and meritoriously-studied case. The symptoms during life exactly simulated those of dementia paralytica. The affection commenced with an entire change in the disposition of the patient; from

being taciturn, quiet, and very parsimonious, he became very excited, restless, and desiring continuously to buy in the shops. Then failure of memory, marked sense of well-being, carelessness and indifference for the future, developed consentaneously with failure of the power of walking, trembling of the hands, inequality of the pupils, and hesitating speech. There was next a period of melancholy, which was in time followed by continuous failure of mental and motor powers, and very pronounced delirium of grandeur, ending in complete dementia. Death finally occurred from universal palsy, with progressive increase of the motor symptoms. At the autopsy, characteristic syphilitic lesions were found in the skull, dura mater, larynx, liver, intestines, and testicles. The brain presented the macroscopic and microscopic characters of sclerosis and atrophy; the neuroglia was much increased, full of numerous nuclei, the ganglion cells destroyed. The vessels were very much diseased, some reduced to cords; their walls were greatly thick-

ened, and full of long spindle-shaped cells, sometimes also containing fatty granules.

Dr. C. E. Stedman and Robt. T. Edes report (*Amer. Jour. Med. Sci.*, lxi., 433,) a case in which the symptoms were failure of health, ptosis, trigeminal palsy with pain (anæsthesia dolorosa), finally mental failure with gradual loss of power of motion and sensation. At the autopsy the following conditions were noted: apex of the temporal lobe adherent to dura mater and softened; exuded lymph in neighborhood of optic chiasm; sclerosis of right Gasserian ganglion, as shown in a marked increase of the neuroglia; degeneration of the basal arteries of the brain.

These cases are sufficient to demonstrate that sclerosis of the brain substance not only may co-exist with a brain lesion, which is certainly specific in its character, but may also present the appearance of having developed *pari passu* with that lesion, and from the same cause.

(To be continued.)

EDITORIAL DEPARTMENT.

PERISCOPE.

A Typical Neurotic.

The *Med. Times and Gaz.*, April 5, 1884, says, that in the life of the late Mr. South, which has been recently published by Mr. Murray, there occurs (p. 135) a vivid description from Mr. South's pen of an illness with which he was seized in 1822, being then 25 years of age. He had been working very hard, he tells us, being every day six or seven hours in the dissecting-room, and in the evenings occupying himself with examining his pupils, or sitting up very late at night writing and drinking half a score cups of tea. In the midst of this work he was unexpectedly brought to a stand by illness.

"On the evening of March 21, 1822, I had gone to bed rather earlier than usual, and had been asleep, I presume, about an hour, when I was aroused by seeing over me a gigantic hand and dagger held over my chest. Everything else in the room I saw distinctly, as it really was. * * * As might be supposed, I was horribly terrified, as I was lying on my back and utterly incapable of moving so as to escape the object of my alarm. At last, however, I managed to change my position, the spectre ceased, and, at the same time I threw up a mouthful of the most acid fluid, which I can only compare to vitriol. I was very much agitated for some time. * * * Next morning I was very ill; had a cobwebby sensation over the left side of my face, and a most curious feeling about the hinder upper part of the left parietal bone, as if my brain were being continually scratched with finger nails, in a space about as big as a crown piece. I do not recollect whether I had any headache, or what the state of my pulse was, but Dr. Cholmeley, who soon came to me, ordered me to be cupped on the scalp and blistered,

and I think I was also cupped in the nape two or three times in the course of a few days and blistered, besides taking calomel and antimony, but not to produce ptyalism. In the course of the week the scratching sensation was relieved, but did not subside. I was soon after attacked with numbness, first of one leg and foot, and then of the other, so that I seemed at these times to be walking with my foot in a pillow. My hands would also become alternately numb in like manner, and in the space between the right thumb and forefinger I had the sensation of a very hot iron resting on it, which sometimes was positively painful. Excepting the scratching in my brain, which continued for some weeks incessant and more or less severe, and the cobwebby feeling, which was not constant, but always restricted to the left side of my face, the numbness in my feet and hands alternated in a very strange manner. Sometimes my foot on one side alone was numb, sometimes the hand on the same side would be numb at the same time, or would be numb alone; at other times my right hand and my left foot would become numb, and then, again, the left hand and the right foot; and these sensations would last a day or two, but without any regularity. But the most persistent was the burning sensation, which was always confined to the right hand. These sensations, at very uncertain periods, continued with me for many years, and were always attendant on any digestive derangement. There was, however, only this exception, that the scratching subsided entirely after two or three years. The severity of this first attack began to diminish about three weeks or a month from its onset, and at the end of six weeks it was thought advisable I should go into the country, and the day was fixed, but on the previous evening, as I was quietly lying reading on the sofa, I was suddenly seized with violent palpitation of my heart,

which being the first time I had felt it, terrified me so much, and was so distressing, that I thought I was about to die immediately. The choking sensation and the violent irregularity of my heart, as if it were being wrung out of place, was most terrific, though I had often witnessed the same condition in my dear father, who for years had been subject to palpitation, always accompanied by severe and continued eructation for two, three, or more hours. After an hour or two the severity of the attack subsided, but my pulse was very irregular, and for two or three days the least exertion, such as merely walking across the room, brought on the palpitation, and for some time I was obliged to lay hold of chairs or anything else at hand, as I had a terrible dread of falling to the ground. [After this Mr. South went to stay in the country, and his health slowly improved.] The palpitations did not cease, although they became less severe. But in reference to them was a circumstance which I could not explain. Whilst I was on horseback and trotting about, I had not any palpitation, and felt tolerably well, but directly I put my foot to the ground the palpitation recurred.²²

Extra-Uterine Gestation.

Dr. W. A. Michie reports this very interesting case in the *Brit. Med. Jour.*, April 12, 1884:

On January 24, 1882, J. C. came under observation, suffering from ulceration of the os uteri, and hypertrophied cervix uteri, with debility, caused by a long-continued leucorrhœal discharge. Eight days later, caustic potash (solid) was applied freely to the os, followed by vaginal injection of dilute acetic acid. Two days subsequently, having been out of bed and been exposed to cold, she suffered from sudden and severe pain in the hypogastrium, which culminated in an acute attack of metritis. The temperature rose to 104°; and the uterus, enlarged and tender, extended upwards to the umbilicus. The acute symptoms subsided in about five days, and, at the end of three weeks, the uterus had regained its normal size. Soon afterwards, she thought herself pregnant, the last menstrual period having been in January. She continued in that belief until August 31, when I had an opportunity of seeing her in bed, from sickness and vomiting. Examination of the mammae and abdomen then revealed signs of an ordinary pregnancy, apparently near the end of the seventh month. Two months later, I again saw her, she having called at my house. I made no examination, but she seemed in most perfect health, and to all appearance a woman near her confinement. I lost sight of her for about five months, until March 21, 1883, when I was called, as she had slight bronchitis and nervous debility. She gave the following account of her case, in the interval, from the end of October, 1882, to March 21, 1883:

Towards what she thought the end of the ninth month of pregnancy, she had frequently recurring pains, as if those of labor, extending over two or three weeks. There were no foetal movements after the eighth, or first week of the ninth, month. In the tenth (and perhaps the eleventh) month, she enjoyed fair health. She entered the Edinburgh Infirmary under Dr. Simpson, about

January 1, 1883, and remained under his care for six weeks; having been told that she suffered from a tumor in the abdomen, for which nothing, under present circumstances at least, could be done, she returned home, and took to bed. She stated that she had menstruated at least twice since she left home until now, and, about the time she left the infirmary, she perceived a slight diminution in the size of the abdominal swelling, and it had continued to diminish until now. Latterly, there had been constant diarrhœa, with paroxysmal and recurring pains in the right side of the abdomen.

I discovered a large movable tumor lying on the right side of the abdomen, extending from the umbilicus into the pelvis, where it could be felt high up through the roof of the vagina, posterior to the uterus, and pressing towards the rectum. The tumor, which was elongated and indurated, was somewhat uniform and smooth on the surface, and painful to pressure in the right iliac region. There had been no bladder symptoms, nor did vaginal examination reveal any uterine displacement, or apparent enlargement. The mass pressing more towards the rectum set up tenesmus, and apparently kept up a catarrh of the bowel. During the next two months, from March 21 to May 17, I saw her on two or three occasions; and at each visit the pain in the abdomen, hectic, tenesmus, and diarrhœa were more marked, while the tumor was sinking more into the pelvis. On May 17, I was called to her. She said there had been constant pain in the rectum for some days with incessant desire to go to stool, and that the pain that day had been excessive and was still increasing. Examination showed the rectum to be blocked with a foetal skeleton, enveloped in a tough fibrous band ruptured at the lower end. After more than an hour's work, the patient being under chloroform, nearly the whole of the skeleton of almost a full-grown foetus was removed from the rectum. One frontal and one parietal bone were removed subsequently. The woman made a perfect recovery, and was out of bed in two weeks.

Perforating Ulcer of the Foot in a Child.

Mr. Edmund Owen reports this interesting case in the *Lancet*, April 5, 1884:

Ellen L—, a girl aged eleven years, was admitted to the Louise ward on December 27 last, for an ulcer which extended deeply into the sole of the left foot at the level of the heads of the metatarsal bones. The sore was almost as wide as the foot, and nearly as long in the antero-posterior measurement as it was from side to side; the adjoining skin was thickly crusted with horny, discolored scabs of epidermis. The foot was stunted, and the toes had been evidently much affected by the long-standing disease, the first appearance of which dated from the time when she was sixteen months old. Small pieces of bone had at various times come away spontaneously from the toes through the ulcer; there was, at the time of her admission, no trace of the little toe, the fourth toe was represented by a small nodule, and the third by a rather larger nodule; the great toe was the only one that possessed a nail. The foot was very warm, and was

covered by beads of perspiration; its dorsal surface was highly pigmented, and possessed a considerable growth of long hairs. There was no marked anæsthesia in the foot, but at the knee of the affected side there was complete absence of tendon-reflex. On the right side also the knee-jerk was considerably diminished. The child had never suffered much pain from the ulceration; there was some glandular enlargement in the groin. There had been no ataxy, crises, or pains; the sore had never been healed from the time of its first appearance. In various parts of the body were extensive patches of pigmentation, the contrast being heightened by the presence of leucoderma in their midst. The pigmentation was noticed at birth; the family history was good. In the course of the previous year the child had been an inmate of the hospital under the care of Mr. Thomas Smith, and from the careful notes which were then taken by Dr. Angel Money, and from those since added by the present registrar, Dr. Chafey, this short report has been compiled. Under the treatment of absolute rest in bed for over two months the ulcer completely healed, though a dusky patch of congested skin has recently appeared upon the dorsum of the foot, which looks suspiciously like the forerunner of another attack of ulceration.

Remarks by Mr. Owen.—During the last few years many cases of perforating ulcer of the foot have been reported in England, almost all of the subjects of them having been adult males. In the adult female but very few cases have been observed, and a report of the condition being found in childhood is of great interest. In general appearance and characteristics this ulcer closely resembled the condition as observed in the adult, and its report is interesting in that it strongly opposes the theory that the *mal perforant* is the result of local pressure. In the adult the ulceration frequently begins beneath or against a part of the foot which is hard and tender from corns. The ulcer in this child was evidently secondary to degeneration of nerve-tissue, and from the absence or impairment of the patellar-reflex on the two sides, the seat of the degeneration must be looked for in the spinal cord.

The Anatomy of the Hymen.

Dr. S. Pozzi has been making some investigations on this subject, which he thus formulates in the *Gaz. Med. de Paris*, February 23, 1884:

1. The hymen is an appendage of the vulva, and not of the vagina; it is formed at the expense of the uro-genital sinus, which also forms a short vestibular canal, this last being the entrance to the vaginal canal.

2. The name *bulb of the vagina* has been unwisely given to the lower part of the vascular plexus, which occupies a prominent position in that canal. There is no ground for distinguishing a distinct organ here, and it should not be compared to the bulb of the urethra in man. It may as well be said that the corpora spongiosa are the analogues of the labia minora.

3. An attentive examination of the vestibular region in woman will show a small band or frænum (*bride*) between the clitoris and the meatus, about two-tenths of an inch long in the adult,

easily recognized by the rectilinear outline of its borders, marked by a median furrow, and divided inferiorly so as to encircle the meatus. When the hymen exists, it appears to be continuous with this frænum. Pozzi proposes to call this small band, now described for the first time, the male frænum of the vestibule (*bride masculine du vestibule*).

4. The study of the balano-urethral frænum—so noticeable in cases of hypospadias—shows the identical connections between that large band and the atrophied frænum (*bride*) of the female.

The bifid condition at the meatus and its continuity with the hymen are easily shown. But in hypospadias it is clear that the frænum is a vestige of the corpus spongiosum arrested in the embryonic stage. The hymen of the hypospadias then, proceeding from the frænum, is an appendage of the corpus spongiosum, and is the terminal part or bulb. This conclusion may be applied to the female organ, and it may be said that *the hymen in the female is the analogue of the bulb of the urethra in man; it is the bulb arrested in the fetal state, non-erectile, and membraniform*. [Henle has noted the frequent presence of cavernous or erectile tissue in the hymen.]

5. The connections of the gland of Bartholin to those of Cowper may be also easily made out. The considerable length of the excretory canal for the male glands, compared with their shortness in the female, should be especially considered. This admits of the opening of the canal considerably in front of the membranous region, at a certain distance in front of the posterior part of the bulb; that is to say, at a point exactly corresponding to the opening of the duct of Bartholin, in front of the hymen, at a certain distance from the fourchette. The opening of Bartholin's gland in the pre-hymeneal portion of the vulva is the origin of that singular lengthening of Cowper's duct.

6. The male frænum of the vestibule in woman is the vestige of the anterior or cylindroid portion of the corpora spongiosa, just as the hymen is the vestige of their posterior or ovoid portion.

Inoculation of Intermittents.

Dr. C. Gerhardt (*Zeitsch. f. Klin. Med.*, vii. 4.) instituted in two individuals the following experiments: He abstracted blood from a patient, while the latter was suffering from a seizure of intermittent fever, and inoculated with this blood two healthy persons. He observed the following precautions:

1. The locality in which the experiment is to be made must be totally free from malaria.

2. The persons whose blood was employed for this purpose must not suffer from syphilis or any other inoculable disease.

3. The persons to be inoculated must agree to the experiment, and voluntarily subject themselves to it.

4. The temperature record of the individuals to be experimented upon must have been carefully kept for some time preceding the experiment, and evince not the least increase of temperature. They must have been at the time of the operation, and for a long time preceding the same, utterly free from all febrile symptoms.

The experiments themselves gave the following result:

1. The intermittent fever, caused in this manner by inoculation, is distinguished from the natural malarial fever by greater irregularity of the attacks of the former.

2. After a number of single or group-wise attacks, a regular quotidian analogous to the form present in the original source, developed itself in the one person on the twelfth day, in the other on the twenty-fifth.

3. The fever, thus artificially produced, reached in both cases such a high degree (temperature as high as 41.1°C ., and deviation of fever fully twenty-four hours), that the experiment had to be interrupted by the administration of quinine.

4. There is no doubt, that the pathogenic element of malaria is present in the blood of a patient suffering from intermittent fever, at the time of a seizure, and that it is then, together with the blood, inoculable.

5. With very few exceptions, all the seizures, by which the inoculated persons were attacked, set in at the hour at which the inoculation had been made, or if they had not done so (as was a few times the case), they reached their acme at that time. The period of incubation was difficult to determine; the first febrile movement made its appearance in the one case on the seventh, in the other on the twelfth day, and the graver series of seizures began in the one on the seventeenth, in the other on the twenty-fifth day.

This agrees with what has been usually taught to be the period of incubation—from seven to twenty-one days.

The Fever of Growth.

The *Med. Record*, April 5, 1884, quoting from *Centrab. für Chir.*, January 26, 1884, says:

This affection, first described by Bonilly, in 1880, is characterized by a fever pursuing a specific course, and accompanied by pain and tenderness in the epiphyses of nearly all the long bones, and is followed by a period of very rapid growth of the individual. It may occur at any time between the fifth and twenty-first year. It is occasioned by excessive exercise, as long walks, standing for a considerable time, fatiguing gymnastic exercises, swimming, etc. Bonilly distinguishes three forms of the disease:

1. Acute, with rapid course, the most common.
2. Acute, but more protracted than the first.
3. Chronic or relapsing (*trainante*).

Fever or tenderness of the bones are common to all these forms. The pain occupies the "juxta-epiphysal" zone, and is most commonly located in the lower ends of the femora, though all the long bones are not infrequently affected. The joints are not involved, as a rule, though sometimes serous effusions, more especially in the knees, are met with. The more rapid form runs its course in from twenty four to thirty-six hours. The second variety may be of several days' duration, and may even be accompanied by typhoid symptoms, but its termination is always by a rapid return of temperature to the normal. The chronic form is characterized by a succession of attacks running along for weeks and months. The prognosis is favorable, though relapses are common. Quinine should be given during the attacks, and in the intervals all fatiguing bodily

exercises should be avoided, while attention is directed to a building-up of the general condition. The following case of growing fever is reported by Dr. Guillier: A child, eleven years old, of rather delicate constitution, was taken suddenly ill with convulsions, high fever, and pain in all the extremities. There was tenderness over the epiphyses of the femur, tibia, and humerus on either side. A slight improvement on the next day was followed by an increase in all the symptoms in the evening. Under antipyretic treatment the fever subsided on the third day. After five weeks the child was able to leave the bed, though she was still very weak. During that time the height increased two and one-half inches.

The Relationship of Malignant Disease to the Food and its Treatment by Diet.

The *Med. Times* says that in a communication to the Académie de Médecine de Bruxelles, M. Van den Corput made a suggestive reference to the etiology of cancer (*Revue de Thérapeutique Med. Chir.*, January 15). Upon considering the geographical distribution of cancer the author found that it was almost unknown in hot countries, and also among certain religious communities in other latitudes which abstain from the use of meat. The only apparent connection between these two classes is the diet. It is apparently, therefore, to an exaggerated animal diet—which at the same time causes an excess of chloride of sodium in the system—that we must look for the principal pathogenic cause in the cancerous diathesis. This must reside in an infection of the organism, either by certain nitrogenized products susceptible of disturbing or changing the normal nutrition processes, or by certain inorganic elements, such as the phosphates, capable of favoring the histogenesis of neoplasms. A confirmation of this view was found in the rapid emaciation of the patients, accompanied by the decreased discharge of urates in the urine. The application of these views to the treatment of cancer is obvious, but it does not appear that the author has succeeded as yet in demonstrating the correctness of his views by clinical investigation.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT MEDICAL LITERATURE.

—Those of our readers who would like to pursue the vivisection question lately aired in our pages, can obtain from the "Woman's Branch" of the Pennsylvania Society for the Prevention of Cruelty to Animals a pamphlet of eight pages in which the ladies offer a reply to the letters of Drs. Mitchell and Wood, which we published. As the matter seems to rest on a question of memory of the gentlemen concerned, we ourselves refrain from expressing an opinion.

—In a reprint from the Indiana State Board of Health, Dr. H. V. Sweringen gives a brief

statement of the importance of ventilation, food, sleep, building, etc., to public health.

—Dr. A. Jacoby, of New York, has a very erudite article on congenital lipoma published as a reprint. He has seen and describes several remarkable cases of this disease, and enters fully into the literature of the subject.

—A noteworthy article is before us by Dr. Chas. S. Turnbull, of Philadelphia, in which he calls attention to the great value of boro-glyceride in the treatment of contagious ophthalmia. This new agent promises to take a leading position in the therapeutics of diseases of the eyes. He uses a fifty per cent. solution. It is especially valuable in the case of young children.

—The report of the Pennsylvania Hospital for the Insane for 1883 contains a full memorial of the late Dr. Thomas S. Kirkbride, who for so many years was physician and superintendent. His name was associated for nearly half a century with the progress of diseases of the mind in this country.

—The Address of the President of the N. Y. Neurological Society, Dr. W. J. Morton, was upon "Neurological Specialism." He strongly advocates the increase of specialists in medicine.

BOOK NOTICES.

Shakespeare as a Physician. By J. Portman Chesney, M. D. 8vo., pp. 226. Illustrated. J. H. Chambers & Co., St. Louis.

The title page of this volume informs us that it "comprises every word which in any way relates to medicine, surgery, or obstetrics, found in the complete works of that writer (Shakespeare), with criticisms and comparisons of the same with the medical thoughts of to-day." These extracts are arranged under the various headings, Obstetrics, Psychology, Neurology, Pharmacology, Etiology, Dermatology, Organology, Chirurgery, and Miscellaneous. It will be seen that out of this net, no medical passage is likely to escape.

The author is evidently a curious reader and a careful student of the great dramatist; and the most versed Shakespearian will find new things in his pages, salt in his remarks, and cunning in his comments.

There are some points about his work which to us mar the pleasure in its perusal. One is the sensational and often slangy headings to his chapters; another, that the type does not distinguish between the extracts and the comments; that too little attention is given to various headings; and that the pictures are badly printed. In the next

edition we hope he will reform these errors, either indifferently or altogether, and thus render his volume more attractive.

Conversations on the Subject of Medical Ethics, with an Account of the Medical Empiricisms of Europe and America. By Frank H. Hamilton, M. D. Small 8vo., pp. 129. Bermingham & Co., New York city.

The much-discussed matter of "Old Code and New Code" is here taken up in an imaginary conversation between two physicians of diverse opinion, and each represents the merits of his own view. Neither is satisfied with matters as they stand, though the one is for more sweeping reforms than the other. Considerable side talk is held of the various 'isms and 'pathies which from time to time have arisen. We observe that the author falls into the common error of supposing that the "eclectic" schools derive their name from claiming to select the best out of all schools; the real origin was that they claimed that medicines have an eclectic effect on certain organs and tissues.

Drugs and Medecines of North America, Vol. I., No. 1.

This very attractive quarterly, of which we have the first number, is under direction of J. N. and C. G. Lloyd, of Cincinnati. It appears that the design is to carry it through the flora of North America in regular order. If this work is to be continued throughout on the same scale as that of the first number, the editors have a great task ahead of them—one in which, however, they must have the good wishes of botanists, pharmacists, and physicians. This number offers 32 pp., 4 full-page plates, and 9 figures. All the illustrations are good and characteristic. The one by Mrs. Stowell is not only artistic, but perfect in anatomical detail.

Plate One, Clematis Virginiana, is absolutely life-like. The order of Ranunculaceæ is only partly finished in the part before us. The type is good, and so far as we may judge hastily of a text involving so much labor, it is exact, and conscientiously done. It is not often that a book gives promise of so much, and then realizes to the last all the good we anticipated from the earlier numbers. We hope this may be an exception to the rule.

Having been thus explicit in regard to the merits, we are bound to be equally frank and say that the alleged or supposed provings given on pp. 15, 24 and 32, can have no value outside of the school in which infinitesimal doses and enormous credulity go together.

THE
Medical and Surgical Reporter,
 A WEEKLY JOURNAL,
 ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
 JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, - - -	2.50
Reporter and Compendium. - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
 115 South Seventh Street,
 PHILADELPHIA, PA.

AN OBSTETRIC CASE

(Price, \$15.00),

OR

AN ELECTRIC BATTERY

(Price, \$25.00),

AS PREMIUMS.

Any subscriber to the REPORTER who will send us before the 1st of July the names of *three* new subscribers with their yearly subscriptions (\$15) or *five* new subscribers with \$25.00, will receive, for the three, an Obstetric Case complete, and for the five, an Electric Medical Battery complete. They are new, of the best make, and of guaranteed excellence. The new subscribers will receive the REPORTER *free* from the date of the remittance until July 1st next.

Address DR. D. G. BRINTON,
 115 South Seventh Street,
 PHILADELPHIA, PA.

WHEN IS A FŒTUS A HUMAN BEING?

Recently in Berlin a very interesting case was tried in the criminal court. K—, a barber, not privileged to perform midwifery, was sent for by a woman in labor. He at once applied the forceps, and in such a butcher-like manner, that he broke the bones of the skull and killed the child. Medical testimony proved that the case was a normal delivery, that there was no indication whatever for the application of the forceps, and that the child would have been born alive had it not been thus roughly treated. Certainly, the quack was convicted. The law in Prussia says, that manslaughter is the careless killing of a human being (eines menschen). The question to be decided, and in such a case having been never previously determined, was: When does a fœtus become legally a human being (ein mensch)? The case was carried before the highest tribunal, and this has decided that a fœtus becomes legally a human being the moment labor has begun. The defense had contended, that as no part of the fœtus had as yet left the mother, and as only one part of it had left the uterus, it still was a fœtus. But the Court remarked, that it would be wrong to consider a fœtus in one act of the delivery a human being, and in another act a fœtus; that its existence as a human being in the sense of the law began at the time when it commenced to break its connection with the mother, when it made its first effort for a separate existence.

While it may, perhaps, be more scientific to consider a fœtus a human being at the moment of its first breath, for the purpose of punishing such an outrageous quackery as that evinced in the foregoing case, the decision, probably, is a wise one. Besides, were the act of breathing alone to decide the question, many cases with technical difficulties might arise, as, for instance, those where, as in cases of breech presentation, or in turning, the feet are first born, and with the interruption of the circulation the fœtus, while still within the body of the mother, makes an effort at breathing, and similar cases. Further, the plainer, the less dubious such a decision, the better for the protection of human society. If it is

once determined that a *fœtus* is a human being from the first beginning of the labor, *i. e.*, at full maturity—there is no room left for doubt, and no opportunity given to a shrewd criminal lawyer to free his client from punishment by mere technical points of law: and this is the reason why we call the decision a wise one.

INFECTIOUS ORCHITIS.

Occasionally cases of orchitis are met with where the individual affected tells us that he has no idea whatever how he contracted the disease. We have more than once known physicians to shrug the shoulders, and insist that the patient, were he to tell the truth, would very well be able to give the cause—gonorrhœa—of his epididymitis. Others again, coming nearer the real pathogenic element, expressed it as their opinion that exposure to cold in persons with rheumatic tendencies, or in such as were formerly suffering from orchitis, was an occasional causing element.

It has now been determined that there exists an epidemic, infectious form of orchitis, which is usually met with in a locality at one and the same time with epidemic parotitis (or mumps) and with epidemic nephritis. In a late meeting of the Berlin Medical Society (February 11, 1884, reported in *Deutsch. Med. Zeitg.*, 1884, No. 16), a debate took place on this subject. Occasionally the disease would begin, said Mr. Croner, with parotitis, and a few days later nephritis develops itself on one testicle, or in females, one labium majus becomes the seat of the affection, while in again others, the inflammation of the testicle alone constituted the disease. Such cases also happen sporadically.

It is, therefore, probable that when a person, otherwise healthy, is suddenly attacked by acute inflammation of the testicle, and especially, when cases of parotitis happen in the same neighborhood, we can take it for granted that he is suffering from the infectious form of the malady; and the same holds good of those peculiar and sudden abscess formations in the large labia of women, an occurrence which heretofore, at least as regards its etiological points, has but too often baffled

the skill of the expert. And in all such cases it may be well to look after the general condition, and especially after the kidneys of the patient; and we ourselves were more than once astonished at the violent general affection in such cases, and at the dropsical symptoms at times appearing. In all, especially infectious diseases of the glandular system, the kidneys seem very prone to participate, as they besides also have a tendency of doing in all febrile infectious maladies, as small-pox, scarlatina, puerperal fever, and even, after Henoch, in varicella. The fact teaches us to use in these cases, with reference to the kidneys, the same foresight and precautions as are generally employed in scarlet fever.

ON TREATMENT BY THEORIES.

It has been several centuries since Bacon wrote his *Novum Organum*, in which he set forth the correct principles of scientific philosophy. They have guided the development of modern thought. In medicine, however, they have had but tardy admission. Even to this day too many of our procedures are controlled by preconceived theories, rather than by the result of observation.

Not only does this apply to those forms of practice which are not recognized as scientific, but also in many departments of our own school. This has lately been very noticeable in methods of treatment based on the theory of germs. It is painful reading to peruse the reports from the Berlin hospitals of the anti-parasitic treatment of phthisis. The patients were selected from a class stated to hold out a fair prospect of recovery. Under the steady administration of nauseating drugs, of irritating inhalations and other germicides, the majority of them died in five weeks, and those who survived longer seemed to owe it to their opposition to a continuance of the treatment.

Inasmuch as the latest researches have thrown great doubt on the alleged discoveries of Dr. Koch, at least so far as they make out the bacillus to be a cause of tuberculosis, the folly of such attempts is only too manifest.

With the constant endeavor of scientists to seek

notoriety by the premature statement of theories of disease, it becomes the part of every prudent practitioner to stick to the old lines of therapeutics, rather than to jeopardize the chances of his patients by running after new things.

We blame the homœopath for his servility to his exclusive dogma; we denounce the eclectic for his vague hypothesis of dynamics; but we are equally to blame when we adopt and carry into practice every new-fledged theory of histologists.

The instance we have given from the treatment of consumption could be easily paralleled from other diseases. Diphtheria, typhoid fever, and cholera, offer numberless examples of wild medication based on unripe observation. The principle we should ever observe is to hasten slowly in any departure from plans of treatment which relieve symptoms and increase the comfort of the sick. Specifics are scarce: many say it is unphilosophical to look for them—at any rate, they are to be sought not through *a priori* theories of disease, but from the results of clinical observation.

SUDDEN DEATH AFTER MORPHIA.

It has now been often observed, that in those cases of organic diseases of the heart in which, due to degeneration of its muscular fibres, the organ is very weak, hypodermic injections of morphia suddenly cause the death of the patient. It is the more necessary to draw the attention of practicing physicians to this fact, as the often very severe attacks of pain, and the seizures of dyspnœa, so characteristic of these heart-lesions in their later stages, are so promptly relieved by the hypodermic medication. In *Fortsch. der Med.*, 33, 1883, Dr. Runeberg's case, reported in the *Centrbl. f. Nervenheilk*, 13, '83, is mentioned, and a number of similar cases added. R.'s case was as follows:

In an army officer, æt. 40, strong and vigorous, and suffering from severe attacks of angina pectoris, R. made a morphia injection of one-quarter of a grain. About two minutes later, patient suddenly gave a start, opened widely his eyes, whose pupils became dilated to their utmost, and—was dead. The autopsy evinced extensive

sclerosis of the coronary arteries. The muscular tissue was degenerated. Neither potatorium nor liver were etiological moments. Though R. believes that the lesion was such as to have caused death at any moment, the subcutaneous injection of morphia evidently accelerated the exitus in R.'s opinion.

Dr. Unverricht, in Breslau, adds to this, that his own experience had taught him caution with the hypodermic injection of morphia in all cases of organic heart-disease, if accompanied by weakness of the muscle; and in conclusion, he mentions Israel's case, where death set in after the injection of one-sixth of a grain of the same drug. The disease here was mitral insufficiency, with grave morbus Brightii, the compensation having ceased. We can contribute one case of our own, where, in a case of fatty degeneration of the heart, the injection of one-sixth of a grain was immediately followed by instantaneous death.

"WOMEN ARE DIRTY CREATURES, ANYHOW!"

This not very complimentary remark was dryly made by a physician of considerable experience among women, during a discussion of Dr. White's remarks before our County Society, which we have noted in our editorial on gonorrhœa. At first we were staggered by the ungallantry of the remark, and wondered at it. A few words more, and we not only realized the full force and meaning of the remark, but felt that it was so eminently true that a few words of advice on the subject would be most opportune.

The remark was meant for the *vagina*, and our friend went on to ask how many women ever syringe out the vagina, unless ordered to do so by a physician, and yet how few women are there who have not some kind of a vaginal or uterine discharge? The old university resurrectionist, Nash, used to say (more forcibly than elegantly) that every man with an elongated prepuce had a cheese-factory at the head of his penis; by which he meant to convey the idea of the accumulation of smegma which occurred in those so formed,

unless they were very particular about washing the glans. So our friend referred to the accumulation and decomposition of the various discharges in the vagina, which must necessarily result in making this cavity a very foul place indeed.

The practical advice suggested by this remark is that all women should provide themselves with a good suction syringe, and at every bath, when the surface of the body is washed, the cavity of the vagina should be well syringed with soap and water.

Extended comment is unnecessary; these few words will suggest to every physician the propriety of such a procedure, and will, no doubt, cause him to give such good advice to all his female patients.

NOTES AND COMMENTS.

Cure of Alcoholic Tremor by Veratria.

The view has been often pronounced that the tremor, as met with in potatoes, in cases of central degeneration, in fevers, etc., really is a muscular contraction, in which the number of oscillations in a unit of time is not sufficient to cause tetanus, and that this may happen as well in consequence of want of innervation as of muscular degeneration. Acting upon this premise, and upon the fact that after small doses of veratria the muscle reacts on every stimulus by contractions more energetic and more continuous than is normally the case, Dr. Basile Feris (Report of Société de Biol. de Paris, Nov. 26, 1883, *Allg. Med. Central Zeit.*, 2, 1884), thought of making use of this drug in the tremor referred to. He administered to such patients daily four pills, each containing the one hundred-twentieth ($\frac{1}{200}$) of a grain, at intervals of one hour each. His 13 patients (10 potatoes, 2 with multiple sclerosis, and 1 tremor after typhoid fever) were perfectly and totally cured of their tremor within a period of from five to fifteen days! Testing them by writing (perhaps the most reliable method to show an improvement in a person suffering from tremor), they all denoted a visible improvement on the very first day, as the tests one hour before and one hour after the first pill clearly demonstrated. F. advises, however, for the sake of precaution, no matter how well established apparently the cure, to continue the treatment for about ten days longer, to prevent relapses from happening. F.

had opportunity to convince himself that in all his cases the improvement had still continued after the lapse of four months.

If this remarkable cure had not been reported by a Frenchman, we would say that an important and highly valuable discovery had been made. But we have been so often disappointed with cures reported to have taken place in France, and which nowhere else would succeed with the same treatment, that we will wait until we hear from other sources the effect of the remedy. It is well known that in all cases of tremor, especially, however, in disseminated sclerosis (and also in drunkards after a glass or two of whisky), a sudden improvement is very apt to take place, no matter what the treatment at the time. In the *Specialist*, Prof. H. Engel published a lecture of his, in which he reported several such cases—amongst others, that of Professor H. R——, who had been suffering from one of the most pronounced forms of multiple sclerosis. Dr. Engel recommended manipulation; the second day, most of the tremor had disappeared. But should a further trial prove the correctness of Feris's observations, the discovery would be a really valuable one.

Phosphide of Zinc.

The *New York Med. Jour.*, April 5, 1884, tells us that in a recent number of the "Gazette hebdomadaire de médecine et de chirurgie," M. Paul Vigier remarks that, although phosphide of zinc contains twenty-five per cent. of phosphorus, it requires to be given in doses eight times as large as those of phosphorus, for in the system its phosphorus enters into combination with hydrogen, and in that state has only half the activity of phosphorus. Leaving the question of dose out of account, however, much of the disappointment that has been met with in the use of the drug is no doubt to be ascribed to an imperfect salt having been used. In the process of making phosphide of zinc, the salt forms in two different states, one part of it subliming, and the other forming a gray, friable mass. The latter form predominates in the process of manufacture, but is very variable in its percentage of phosphorus. An eighty-per cent. phosphide answers every purpose, but all below sixty per cent. should be rejected. The following convenient method of assay is given: 0.586 gramme of the phosphide, wrapped in a piece of cigarette paper, is introduced into a graduated gasometer, inverted over mercury, and containing 8 ccm. of hydrochloric acid. If the phosphide is pure, it ought to disengage 100 ccm.

of phosphoretted hydrogen completely absorbable by a concentrated solution of sulphate of copper; an eighty per cent. phosphide will disengage 80 ccm. of the gas, and so on.

A New Remedy for Scarlatina-Dropsy.

Dr. P. Heuser writes to the *Deutsche Medicinal Zeitung*, 16, 1882, that he has nearly always achieved a rapid cure in scarlatina-dropsy, and even when internal remedies could be no longer administered, by the following method:

He daily rubs into the skin in the region of the kidneys a mixture of one part of croton oil, with two parts of ol. papaveris. Mostly one such injection suffices to cause within a few hours the appearance of a severe eruption of the skin, and simultaneously a great improvement in the condition of the patient, and amelioration of all the dangerous symptoms. The change for the better at once sets in with the commencement of the artificial exanthem. If the symptoms again become aggravated, the procedure is repeated. Internally H. administers spirit. mindereri in small doses.

During the time we were in Berlin a quack had probably saved the life of a child suffering from uræmia after scarlatina latens, by employing Baunscheidtismus over the region of the kidneys. This, as is well known, consists of an instrument which is applied to the skin, when by a snapper-like arrangement (as in wet cups the knives), 30 to 50 fine needles are suddenly let fly into the skin. These needles had previously been dipped into diluted croton oil. An eruption followed, and diuresis was re-established.

Localization of Tactile Sensations.

The investigations which have for their object the localization of the cerebral functions, still continue. The motor-sphere is no longer disputed by anybody. Some, as Munk, contend that the sensation of touch also has its centre in the ascending parietal convolutions—the seat of motion, *i. e.*, its will-centre. Recently, Dr. Bechterew, in Petersburg (*Neurol. Centrblt.*, 18, 1883,) has again taken up this subject, and thus far comes to the following conclusions:

After removal of the so-called motor-sphere in animals, they evince no impairment of any of the following sensations: That of touch, of position (tactile-sense, locality-sense), general sensation, and perception. They have lost only the voluntary motion in the affected extremity. For the perception of tactile impressions, for the muscular

sense, and for painful sensations, special centres exist, which are situated near the motor-sphere. The centres for tactile sensations lie immediately posteriorly and externally to the motor-field, while the centres for the muscular sense, and those for painful sensations, occupy the region immediately above the beginning of the fossa Sylvii. The two last-named centres do not lie one above each other, but the one bordering the other; for in cases of limited lesions of this cortical zone, either a disturbance of the muscular sense of the contralateral extremities, or only that of painful impressions is noted.

Bichloride of Mercury in Diphtheria and Croup.

Dr. William M. Thallon contributes two articles on this subject to the *N. Y. Med. Jour.*, April 12 and 19, 1884. Dr. Pepper, of this city, is a great advocate of this treatment. He uses it in large doses, with the following rules to guide him: If the false membrane is increasing, he increases the drug; if it is stationary, he maintains the same dose; if it is decreasing, he diminishes the remedy; and if the membrane has disappeared, he at once stops the bichloride.

He has found it convenient to have two standard formulas, according as he wishes to combine iron with the mercury or not. He generally writes for a three-ounce mixture, with half a grain of the bichloride, so that each teaspoonful contains about one-fortieth of a grain. The following are his prescription models:

FORMULA I.

- | | | |
|----|-------------------------------------|--------------------|
| R. | Hydrargyr. bichlor., | gr. ss. |
| | Tinct. ferri chlor., | f. ʒ iij. |
| | Glycerin., | f. ʒ ss. |
| | Aquæ, | q. s. ad f. ʒ iij. |
| M. | Sig. f. ʒ j. as directed, in water. | |

FORMULA II.

- | | | |
|----|-------------------------------------|-----------|
| R. | Hydrargyr. bichlor., | gr. ss. |
| | Vin. pepsin., | |
| | Elixir bismuthi, | āā ʒ iss. |
| M. | Sig. f. ʒ j. as directed, in water. | |

The second formula is the pleasantest way of prescribing the remedy, and it is the one used by Dr. Pepper.

Practically, he now generally begins with the second formula, and, when convalescence has commenced, resorts to No. 1 to get the benefit of the iron.

He does not attempt to explain the action of the bichloride; but bases his claim that it will give better results than other treatment known at present, entirely on clinical evidence. An important point is that the drug should be well diluted, whereby its irritating properties are avoided.

Statistics of Diphtheria.

The *Med. Times and Gaz.*, March 15, 1884, tells us that M. Florand supplies to the *Revue Mensuelle des Maladies de l'Enfance* some interesting statistics relating to the cases of diphtheria, admitted to the Hôpital Trousseau, in Paris, during 1883. There were 606 cases of diphtheria admitted, of which 165 were pharyngeal, while 441 affected the larynx, or air-passages. Amongst the 165 cases of pharyngeal diphtheria, there were 65 deaths, making a mortality of nearly 40 per cent. The 65 deaths included ten from paralysis, the rest dying from the toxic effects of the disease, or of measles, or scarlet fever. Of the 441 diphtheritic croups, 359 were operated upon with 244 deaths, a mortality of 68 per cent. The 359 cases operated upon included 40 cases of croup complicating measles, and 30 who were under two years of age; and among those who recovered after tracheotomy, there was an infant of thirteen months, three under twenty months, and two which were complicated with measles. The cases which were not operated upon were for the most part those cases in which there was wide-spread diphtheria of both pharynx and larynx, and which were moribund when admitted. These results are said to be the most satisfactory which have been obtained for many years at the Hôpital Trousseau. It is interesting to note that several cases of paralysis occurred after laryngeal diphtheria, thus pointing strongly to the identity of pharyngeal diphtheria and "membranous croup."

New Method to Determine the Percentage of Cream in the Milk.

The present method is a very troublesome one, and occupies considerable time. In the last meeting of the Society for Natural Philosophy in Frankfort-am-Main, Dr. Lepsius described Foxhlet's new method, which is as follows: A potash solution is added to the milk, and the latter then shaken with ether. With fine aerometers the percentage of fat can be then easily determined in the ether. It is said, that while this method permits the same accuracy as the old one, it has the great advantage of great rapidity. In the same meeting the subject of the value of skimmed milk as a nutritive substance was also debated. It was generally admitted, that on account of its cheap price and percentage of albuminous material—this not being at all diminished by the removal of the cream—skimmed milk is of great value, especially for the poorer classes. At the same time it was shown, that milk with the cream left in it, but diluted with water, loses

in value as a nutritive substance, as the same percentage of albumen is no longer contained in the fraudulent fluid. They all agreed that substances of such a common use as milk should be daily inspected by a government official, and any fraudulent admixture be made widely known.

Treatment of Burns and Scalds.

Dr. C. F. Naismith writes to the *Lancet*, April 12, 1884, that he has secured most excellent results from the following method:

At first he used the soda solution, followed by carron oil, but soon abandoned them as unsatisfactory. The former owes its reputation to the cold water, and not to any soothing property in the soda. His invariable practice, however extensive the scald, has been to place the injured member in ice-cold water, keeping it there till all pain has disappeared—say in from two to four hours, or even longer. The water heats rapidly, and must be kept cold either by ice or constantly renewing. As long as the scalded part is kept under water (provided it is cold enough) no pain is complained of, and symptoms of shock are much lessened. When the limb will bear removal from the water without pain, he lays on thickly lead acetate and resin ointment (one drachm to one ounce), and envelopes in cotton wadding. He has used this ointment also in erysipelas with the best results, all symptoms of inflammation rapidly disappearing. Should severe suppuration occur, instead of the lead acetate a few drops of creasote may be added to the resin ointment, as recommended by Druitt. By this treatment pain and shock are reduced to a minimum, opiates are seldom required, and danger to life is, he believes, greatly averted.

Treatment of Compound Fractures of the Skull.

From the *Brit. Med. Jour.*, March 22, 1884, we learn that Dr. Barling gave before the Midland Medical Society, an abstract of nineteen cases of compound fracture of the skull treated by trephining, and drew attention especially to the mortality after operations, when symptoms had arisen, or when the dura mater was wounded. Of the nineteen cases, nine recovered, all being operated upon immediately after the injury, and the dura being unwounded. Immediate trephining was advocated in all cases of compound depressed fractures, and in incised and punctured fractures, whether symptoms existed or not. If there was any doubt as to the condition of the internal table, it was suggested that the external table might be re-

moved by the trephine, and the state of the inner layer determined. In the list of cases produced, intra-cranial abscess happened three times—one of the patients recovering. The symptoms of intra-cranial abscess were reviewed, especially with reference to their bearing upon these three cases, and the difficulty in localizing the position of the pus. Exploration of the dura mater, and if necessary of the brain substance, was urged, in the presence of indications which might suggest intra-cranial abscess.

Goitre or Cretinism.

From the *Boston M. and S. Jour.*, April 24, 1884, we learn that a curious pathological fact is related by M. Guillaume Chapus in a memoir, "Sur les Médecins et la Médecine en Asie Centrale," which is noticed in a French journal. One town of Turkestan, Kokane by name, is composed in great part of individuals afflicted either with goitre or cretinism. The traveler is struck with the appearance of the inhabitants, who present all degrees of goitre, from a slight fullness to enormous thyroid tumors. The peculiarity in the case consists in the fact that outside this one town goitre and cretinism are very rare. In Kokane the hygienic surroundings seem to be most satisfactory. It is situated in a plain at an elevation of 1300 feet, and is abundantly supplied with pure water from a mountain stream. In 1878 the Russian troops occupied this town, and it was discovered that about a tenth part of the soldiers of the garrison became affected with goitre after a few months' stay. The tumors proved amenable to the external and subcutaneous use of iodine. It was considered prudent, however, to remove the garrison from Kokane, and another town of less pathological interest was selected as the political capital of the province.

Tenacity of Tubercle Bacilli.

It has been doubted whether the sputa of tubercular patients, which are thrown on the streets and later mix with all kind of dust, would ever cause the disease. To determine this question, Dr. Vignal (*Deutsche Mediz. Zeitung*, 1884, No. 1) has collected sputa, as they had been expectorated by phthisical persons in the streets. He mixed them with the common street dirt, moistened them, put them on a porcelain plate, suffered them to dry, again moistened them, again let them dry, and continued these experiments for a very long period of time. Then he made inoculation from these sputa in two Guinea pigs; one

died a few days later from a different, accidental complaint, the other first became fat—a proof of the experimenter's good feeding—then slowly emaciated, and finally, three months later, died. The post-mortem showed a large number of tubercles, many in the state of caseous degeneration, and a great number of bacilli.

This experiment proves that the sputa collecting in the streets and on the floors of dwellings, are by no means innocuous, but serve as pathogenic elements in persons predisposed to this disease.

Albuminuria in Zymotic Diseases.

Those who have been accustomed to look upon albuminuria as an exceedingly common sequel or concomitant of scarlet fever, will be surprised to learn from the *Brit. Med. Jour.*, April 12, 1884, the following from Dr. Middleton, of Glasgow:

"He recorded his experience of the occurrence of albuminuria in the continued fevers, as observed while resident in a fever-hospital some years ago. The conclusions at which he arrived were, that albuminuria occurred in over 85 per cent. of cases of enteric and typhus; that it occurred early in both fevers, from about the end of the first week onwards, lasting generally till convalescence was thoroughly established; that abundance of albumen indicated a severe case, but severe cases were not necessarily associated with abundance of albumen; that tube-casts, hyaline, epithelial, granular, and bloody, were frequently present, and, when abundant, indicated a severe case, especially in enteric fever; and that *albuminuria was probably more common in the febrile stage of typhus and enteric than in the febrile stage of scarlet fever.*"

Sudden Death in Diabetes Mellitus.

From the *Jour. de Med. de Paris*, Feb. 9, 1884, we note that Frerichs has observed (*Zeit. f. Klin. Med.*), the mode of death in 400 cases of diabetes, a considerable number of whom died suddenly. In these instances there was one common characteristic—the final coma. This, however, developed in different ways. Sometimes death was extremely rapid, and caused by a general weakness. At other times it was not so rapid, beginning with cerebral symptoms and a form of dyspnoea, with or without cyanosis, the breath having an odor of acetone or chloroform—this form lasting from three to five days. In a third series of cases the coma gradually developed and deepened without any of

the cerebral manifestations or dyspnœa, but the breath had the same odor as that mentioned above. Frerichs thinks that in the first series the cause of death is paralysis of the heart from degeneration of the muscle; in the two latter groups, that it is brought about by a "diabetic intoxication," the poison of which is unknown, but the substitution products are acetone and acetylic acid.

Effect of Decomposed Flour.

Whenever in consequence of the eating of flour, in the form of bread or otherwise prepared, intoxication developed itself, the latter has been always ascribed to the presence of ergot. Of late it has been proven that the ptomaines (alkaloids forming in decomposing, rotten flour) cause the poisoning, and Prof. J. R. Tarchanow (*St. Petersburg Med. Wochenschrift*, 35, '83) has now demonstrated by experiments that, while the presence of ergot will increase the severity of the symptoms, make the poison more intense, the same intoxication, usually observed after eating products of flour, is produced by the ptomaines without the ergot, and that the length of deviation of the decomposition is of far greater influence on the danger of eating such flour than the presence of ergot, and that on the fifth day of decomposition the ptomaines have the most violent effect, and are then utterly uninfluenced by the presence of ergot. This seems to prove, what Virchow has long ago indicated, that the poisoning from sausages is probably also due to ptomaines.

Membranous Cast of Bowel.

To the Sheffield Medico-Chirurgical Society (meeting March 6, 1884), Mr. Edward Barber gave particulars of a case of chronic inflammation of the bowels, attended with the passage, *per anum*, of large quantities of false membrane, which were, in fact, casts of the bowel. He exhibited the quantity that had been voided in the preceding twenty-four hours. The membrane was of a soft gelatinous consistency, and of a greenish-brown color. The patient was a woman, aged 37, who had been married fourteen years, and had had no children. She suffered a good deal from neuralgia, was of a dull and desponding nature, and was beginning to exhibit symptoms of pronounced hypochondria.

Dr. Law and Dr. Banham referred to similar cases that had occurred in their own practice.

Dr. Keeling pointed out that there was an essential difference between the membranes exhibited and those given off from the uterus in cases of membranous dysmenorrhœa.

Hypodermic Injection of Anthelmintics.

Experimenting with santonate of sodium Dr. Dubois (*Allg. Med. Centr. Zeit.*, 1884, No. 1) made a hypodermic injection of sixteen grains of the drug in a dog. Shortly after, an immense quantity of seat-worms were discharged by the bowel. Not a single untoward symptom, either general or local, followed this method. It would be desirable to have this procedure tried in a larger number of cases, certainly in the human being, for our present way of eliminating worms still leaves a great deal to be desired. Some of the anthelmintics have a miserable taste, or, to be effective, they have to be swallowed in larger, and again in others, in often-repeated doses. The subcutaneous method, if successful, would soon simplify matters and more exactly define the doses necessary, and the irritation of the intestinal canal would be avoided. There are many persons suffering from worms in our country; and many a reader may now have the chance of increasing his reputation and enriching our knowledge by determining the question raised.

Extraction of Teeth by India-Rubber Bands.

In pursuance of this subject, which we mentioned some time since, we note the following in the *Brit. Med. Jour.*, April 12, 1884, from the pen of Dr. H. W. Peard:

In answer to "M. R.'s" query, I would say that the smaller red rubber-bands, such as are used for putting around papers, etc., are capital things for extracting teeth, when applied sufficiently tightly. I used these bands (about two-thirds of an inch in diameter) successfully in two instances. There is no special method, that I am aware of, in using these bands; it is only necessary that one should be twisted several times around the tooth, as close to the gum as possible. The period between the application of the band and the extraction varies, as well as I can ascertain, from one to four days. My experience, I must add, has as yet been only of incisors and bicuspsids.

The Poison of Diphtheria.

The Empress of Germany has awarded the prize for the best work on diphtheria to Professor Otto Heubner, in Leipsic. He proves that in case of suppressed circulation (by occlusion of the capillaries) in the submucosa, œdema, inflammation, and mortification with formation of false membranes, issues in the mucous membranes (Cohn's view); that the poison of diphtheria is still as unknown as that of morbilli, scarlatina,

etc., and that that form of diphtheria heretofore artificially developed in animals is by no means identical with that observed in human beings; and that any substance, causing the above-mentioned morbid condition (occlusion of vessels of supply) will give rise to artificial diphtheria. The proof is clear, and upsets all American discoveries of the micrococcus of diphtheria.

Resection of the Rectum.

Especially in older age, prolapsus of the rectum sometimes is a very annoying symptom. Prof. Mikalicz, in Krakau (*Gazeta Charsha*, 1883, 47) dissected off a 76 ctm. long piece of the rectum. The success was a brilliant one. No untoward symptoms developed themselves, and the case was a radical cure. He simply cut off the whole prolapsed part, save one inch of it; to this he applied the necessary sutures, and then made a reposition of the stump. Dr. Weinlechner (*Deutsche Mediz. Zeit.*, 1, 1883,) at the same time presented to the Vienna Medical Society a woman, æt. 61, in whom he had applied a ligature, in this way cutting off the prolapsed part. On the sixth day from the commencement of the strangulation the prolapsed part dropped off, and the patient was permanently cured.

An Enormous Urinary Calculus.

From the *Med. Times and Gaz.*, March 22, 1884, we learn that at a meeting of the Calcutta Medical Society, Dr. Cayley gave an account (*Indian Medical Gazette* for January) of a case of calculus occurring in a native about fifty years of age, who had for some three years suffered from symptoms of stone, which of late had become very urgent. Lateral lithotomy was attempted, but could not be executed on account of the great depth of the perinæum, and the large size of the calculus. Even after the suprapubic operation had been undertaken, its extraction was found very difficult, as it nearly filled the bladder. When removed, it weighed 25½ ounces. The patient died two days after the operation, and no autopsy was permitted.

Abscess of the Kidney.

In *Prager Med. Woch.* No. 47, 1883, we note that J. Singer reports the case of a man, æt. 25, who, when seven years old, had a fall, from which he had hæmaturia; since that time he has had occasional pain in the region of the left kidney. After an attack of typhoid fever he began to pass blood and pus in the urine, and on examination a fluctuating tumor was found in the left hypo-

chondrium. The tumor then began to disappear, and the man recovered. Singer thinks that the abscess must have discharged into the pelvis of the kidney.

Vicarious Hemorrhage from One Mamma.

The thirty-years-old wife of a peasant asked Dr. P. Beloussow (*Deutsche Med. Zeit.*, 16, 1884,) for advice concerning a secretion of blood from her left mamma. Her menses had made their appearance when she was fifteen years old; in her twenty-fifth year they had suddenly ceased, and after five years of amenorrhœa reappeared, but in a very moderate degree, and simultaneously blood had come drop by drop from the breast. This symptom has since continued without any interruption, only the secretion of blood from the mamma becomes augmented in quantity during menstruation.

B. really succeeded several times in causing a dropping of blood from the mamma by a very light touch; the blood was dark and coagulated.

Can a Man Affected with Syphilis Communicate the Disease to a Healthy Fœtus without Infecting its Mother? Can a Man Beget a Syphilitic Child without Infecting its Mother?

Dr. William R. D. Blackwood discusses this question in the *Med. Times*, April 19, 1884, and thus concludes from the observation of three cases in his late experience:

"The three cases herein noted show, to my mind at least, that, first, a fœtus carried by a non-syphilitic mother and begotten by a non-syphilitic father can be syphilized before birth, and the mother escape constitutional taint; and, second, that a healthy woman may conceive through a syphilitic husband, give birth to a syphilitic child, and, notwithstanding, escape constitutional taint."

Disturbance of Vision and Menstruation.

In the meeting of the French Academy of Medicine of February 19, 1884 (reported originally in the *Deutsche Mediz. Zeitung*, February 25, 1884), Dr. Dor mentioned the case of a young girl, suffering from intermittent hemorrhages of the aqueous humor. As soon as the menses made their appearance, the bleeding in the eyes ceased. In a second case, also of a girl, he found her suffering from hysterical amaurosis. The most searching examination of the eyes failed to reveal any morbid lesion, or the least structural change. The amaurosis disappeared when the menses set in, and the young girl had later normal vision.

Simulation of One-sided Blindness.

To discover simulation of one-sided blindness Dr. Bravais (meeting of French Acad. of Med., February 19, c. report *Deutsche Med. Zeit.*, 16, 1884,) recommends the method of Snellen. This latter consists in the fact that if one writes with a red pencil on paper, the letters written cannot be recognized if seen through red glass. If one holds before the apparently healthy eye a red glass, and before the pretended blind eye any kind of glass, or none at all, and requests the simulator to read the red letters on the paper (which have not been before shown to him) and he can read them, the evidence of his simulating is clear; if the second eye had really been blind, he would not have been able to recognize the red letters through the red glass.

Varicella Nephritis.

Prof. Henoch tells us in a recent issue of the *Berlin Klin. Woch.* that he has never read of nephritis following varicella, and yet he has recently observed four cases. In all the cases, at the end of from eight to fourteen days from the appearance of the eruption, there was œdema with albuminous urine and tube casts. In three of the cases, recovery took place in a few weeks, under the use of diaphoretics, with Bilin water or acetate of potash as a diuretic. One, a girl aged two years, who was the subject of congenital syphilis, died; and after death there were found œdema of the lungs and hypertrophy of the left ventricle.

CORRESPONDENCE.

Cretaceous Deposit in the Placenta.

EDS. MED. AND SURG. REPORTER:—

I notice in the issue of May 3, 1883, of the MEDICAL AND SURGICAL REPORTER an article from the pen of Dr. W. H. Dearing, of Malvern, Iowa, entitled "Partial Ossification of the Uterine Surface of the Placenta." While visiting in Iowa last September, I was called in consultation to a case of obstetrics, of which the above cited case reminds me:

The woman, a primipara, aged 27; labor tardy. This was probably caused by a slight narrowing of the inferior strait of the pelvis. After waiting nearly twenty-four hours, it was decided to deliver instrumentally. This was done without trouble or accident, save a very slight rupture of the perineum; the placenta also came away without trouble, but on examining it my friend, Dr. W., called my attention to its uterine surface, which was completely covered with what seemed to be calcareous deposit. Knowing that the water in that section was highly impregnated with lime

salts, and thinking this the probable cause, and that it *might* be a frequent occurrence in this locality, it was dismissed from my mind till seeing a case related by a physician residing in the same State.

W. H. DUDLEY, M. D.

Norwich, Conn.

Note to Article on Hemorrhages of the Ear.

EDS. MED. AND SURG. REPORTER:—

In the MEDICAL AND SURGICAL REPORTER of March 29, 1884, I omitted to notice that in case of falls upon the head, bleeding of a severe and protracted nature takes place from one or both ears, followed by the escape of clear fluid, and this is one of the important and characteristic signs of fracture of the base of the skull. This fluid is from the subarachnoid space. Sometimes a serous discharge may come from the labyrinth, and this is to be distinguished from the cerebro-spinal fluid by the large quantity of albumen which it contains, and which can be coagulated by heat and nitric acid. The cerebro-spinal fluid contains double the quantity of chloride of sodium, and only a trace of albumen, so as not to be coagulated by heat and nitric acid. I also notice in my work on "Diseases of the Ear," p. 116, that at times severe bleeding takes place after removal of fibro-gelatinous polypi from the ear, but is generally relieved by syringing the canal with ice water. Hemorrhage frequently follows the operation of Wilde's incision for deep-seated abscess or perforation of the mastoid cells, but fortunately pressure can be applied with a pledget of cotton saturated with Pancoast's styptic solution or the persulphate of iron. If the transverse sinus is opened by mistake, this is to be plugged with ivory or wood. (p. 196, op. cit.) In Bright's disease of the kidneys, I have found the middle ear filled with blood, being a vicarious hemorrhage which destroyed the integrity of the hearing by pressure upon the labyrinth.

LAWRENCE TURNBULL, M. D.

Philadelphia.

A Case of Conception Without Intromission.

EDS. MED. AND SURGICAL REPORTER:

Mrs. A——, aged nineteen, a native of Ireland, called on me for an examination. She had menstruated regularly and comfortably until after her marriage, some three months previously. As coition was out of the question, her condition seemed to her a mystery. On examination, I found the hymen closing the os externum.

After a long and diligent search, found a foramen close under the urethra, where I depressed the hymen half an inch, and introduced a number eleven bougie, and with my finger in the rectum, succeeded in penetrating a distance of nearly two inches through the firm, inelastic hymen, when the point plunged into the vagina. This condition was undoubtedly congenital.

All of her symptoms indicated pregnancy. Dilatation was tried without success, then I operated with director and scalpel.

In six months after, I attended the lady in confinement, which was normal, and she had a good recovery. In this case the spermatozoa were abandoned in the depression of the hymen, and traveled through the narrow channel two inches

long into the vagina, and continued their journey to the uterus to fecundate the ova.

This fact, with others of the same kind, demonstrate not only the possibility, but the actual accomplishment of impregnation, where the spermatozoa were abandoned a long distance from the uterus.

Philadelphia, Pa.

Treatment of Pruritus Ani.

EDS. MED. AND SURG. REPORTER :—

E. R. S. asks for a treatment of pruritus ani, and also of ascarides. The causes of pruritus ani are either general or local. Sometimes the cause is entirely local; but most frequently it is both general and local. These causes should be, if possible, ascertained. The patient should be instructed to wash his anus well with a cloth wet with cold water immediately after each action of the bowels—this cleanliness is an exceedingly important agent in the treatment of the disease—and after so washing and drying himself, to bathe his anus well with the following:

R. Hyposulphite of soda,	3j.
Carbolic acid,	grs. x.
Glycerine,	3j.
Aqua distil.,	3 vij. M.

For a lotion.

Whenever the itching returns the application of the lotion is to be repeated and continued until the disease is arrested. Sometimes a good result is obtained by dusting over the anus the following:

R. Iodoform,	3j.
Tannic acid,	grs. x. M.

For a powder. Use two or three times a day.

I have found an injection of two ounces of an infusion of pulv. aloes (3j. to the pint of boiling water), night and morning, with a teaspoonful or two, twice or thrice a day, for three or four days, of the following mixture, to be most efficient in the removal of ascarides:

R. Santonin,	3j.
Pulv. jalap.,	3ij.
Fld. ext. spigelia,	3j.
Fld. ext. senna,	3ss.
Syrup sarsaparilla comp.,	3jss. M.

Shake well. Sig., Dose, one to two teaspoonfuls three times a day, followed in a few days, if indicated, with suitable doses of mur. tinct. of iron in an infusion of quassia.

J. B. JOHNSON, M. D.

Washington City, D. C.

Treatment Wanted.

EDS. MED. AND SURG. REPORTER :—

I have been treating the following described case for about eight months with but little success. If some of your readers would give a treatment for it, it would greatly oblige both me and my patient:

Female; age, fifty-seven years. Change of life occurred about eight years ago. Has been healthy, with the exception of the present trouble, ever since. Weighs about 145 pounds. Tall, light complexion, good appetite. Her trouble consists in an intense pain at the pit of stomach, which will dart to the region between shoulders, or

small of back, thence back to pit of stomach; pulse, 72 to 80, very full and strong; temperature, normal; bowels and kidneys regular. The attacks are usually preceded by pain in left foot and ankle, and sometimes left leg, and end by severe vomiting of a large quantity of bile which produces prostration. When cut short by morphine, it requires from one to four days for recovery. The attacks occur irregularly, with an intermission of from five days to three weeks.

My treatment has been varied. I am always compelled to give, sooner or later, morphine by hypodermic injection, which always makes her very sick. Other narcotics, as bromide of potash and chloral hydrate combined, chloroform, laudanum, paregoric, have been tried without relief, while chlorodyne was used with relief for a while only. Treatment in intermission consisted in giving quinine, muriate of ammonia, arsenic, phosphate of soda, and tonics (iron, arsenic, strychnia, etc.) quinia doing the most good of these. During one attack, I attempted bleeding, but succeeded in taking only a little blood; the attack, however, was short and light.

Reelsville, Ind.

G. W. S., M. D.

Salicylic Acid in Cerebro-Spinal Meningitis.

EDS. MED. AND SURG. REPORTER :—

In the REPORTER of March 29th, I notice a malicious personal reply, by Dr. J. B. Weener, to an extract in your number of March 8th, from an article published by me in the February number of the *St. Louis Cour. of Med.*

The article in question was read three months or more before its publication, at the meeting of our County Medical Society—Dr. Weener being present and president of the society.

After the paper was read, and in the presence of the members present at that time, he arose and said that he could testify to the good effects of the salicylic acid in cerebro-spinal meningitis, but never once making any claim whatever to priority in using it.

Among the physicians present were Drs. E. V. Spencer and S. H. Pearse, of this place, Dr. L. B. Bitz, of Blairsville, and Dr. E. H. Gregory, of St. Louis, Mo.

The article was prepared especially for the County Medical Society, I having been appointed to read a paper at that meeting; and being advised by two prominent medical men to publish it, remembering a principle inculcated from my preceptors, that whether young or old, if you know you have learned something that is valuable to the profession, make it known, or you will be doing a great wrong, I did so.

For two years after the occurrence of the epidemic here, I investigated the subject thoroughly, and read the history of epidemics that occurred elsewhere; and it was only after deliberation of this character that I became aware of the value of my success with this treatment. Neither Dr. J. B. Weener nor any other person ever suggested to me a single idea or word that occurs in my original article. I used the salicylic acid in solution, prescribing liq. ammon. acetat. as the solvent.

My age and conditions of partnership once made with Dr. Weener are of course strong (?) arguments against the value and truthfulness of my

statements, and deeply interesting (?) reading for a medical profession hunting for something practical.

As to there being in our profession "young men who like to air themselves, appear in print, and have their names sounded abroad in the land," it has also been said that there exist within our ranks old men, who are fogies, croakers, and have petty professional jealousies, that influence them to such an extent, if seeing an article in a medical journal with the name of a professional neighbor (younger than themselves) attached to it, they write a reply (never having had anything occur, in a practice of twenty years or more, in their opinion worth publishing), giving the author's age, claiming the idea as their own and only, and inclosing it with great care in personal insinuations.

At least, it is queer that one would at so late a date, after a paper being read in his presence before a body of medical men, make such a statement, and publish it in a journal foreign to the one in which the original was published.

I would have replied sooner, but could not until now obtain a copy of the *REPORTER* which contained the statement. D. C. RAMSEY, M. D.

Mt. Vernon, Ind.

NEWS AND MISCELLANY.

Tuberculosis.

A CARD FROM DR. SHAKESPEARE.

Dr. Shakespeare, in discussing the question of tuberculosis, opened by Dr. Formad at the recent meeting of the American Medical Association, stated that he had accepted the invitation of the committee under a misapprehension of the extent of time that would be devoted to the consideration of this most important matter. He did not believe that a mere expression of opinions, without a full examination of the grounds upon which they are based, could have any weight in the settlement of such grave questions in pathology. The time allotted for this discussion could neither do justice to the subject, nor credit to the Association or those taking part in the debate. With this protest, he expressed himself as follows:

1. He admitted, as absolutely proven, that the tubercle bacillus is usually present in tuberculous lesions; that it is usually present in the sputum of phthisical patients; that when present it constituted a most valuable diagnostic sign of the presence and activity of the tuberculous process; that it has characteristics by which it can be easily and certainly distinguished from other known bacilli.

2. He considered it established, by overwhelming evidence, that the tuberculous process once started in any part, other portions of the animal economy can thence become infected by transportation of the pathogenic agent.

3. He regarded it as demonstrated, that there is something in the tuberculous lesions of one animal which, when transported to and properly implanted in the tissues of another animal "receptive" or predisposed to the disease, can excite the tuberculous process in that animal.

4. He believed it amply proved that the tubercle bacillus is virulently capable of exciting and continuing the tuberculous process in living beings when, after introduction, it meets conditions favorable to growth and propagation.

5. He thought that there exists abundant support for the belief that the human race is largely "receptive" or predisposed to the tuberculous process, and he could not escape the conviction that the tuberculous process in man and in lower animals is essentially the same, with respect to its cause and its course.

5. He therefore was forced consistently and logically to admit that tuberculosis is often an infectious disease, and is often caused by the tubercle bacillus acting as a specific pathogenic parasitic agent.

On the other hand, whilst he was not now ready to concede that, by actual proof, it has been shown that no other agent than the tubercle bacillus can excite the tuberculous process, he at the same time most strenuously denied that it has been satisfactorily proven that anything else is endowed with such a power.

Entertaining these views, he recognized the importance of the destruction of excretions containing bacilli or their spores, and so appreciated the danger of possible infection of the well by the sick, that he would forbid the occupation of a common bed in private dwellings, and would, when possible, isolate phthisical patients in hospitals from those otherwise afflicted.

During his remaining time, Dr. Shakespeare adversely criticised Dr. Formad's acceptance of the etiology of tuberculosis.

In the first place, the methods which had been followed of preparation of sections of tissue for microscopic examination were not only incapable of demonstrating peculiarities in the lymph spaces of connective tissue, but they were not such as would make the lymph spaces extremely difficult, if not indeed quite impossible to see at all. In the second place, the tissues examined comprised only the cutis, the subcutaneous connective tissue, and the intermuscular connective tissue. The investigation did not extend to the lymph spaces of the lungs, the liver, the spleen, the kidneys, or the brain. Yet every one well knows that it is not in the skin or in the intermuscular connective tissue that the tuberculous process works, but almost always in the above-named viscera. In the third place, Dr. Formad unknowingly has himself laid the foundation of an objection to his theory, which by itself is fatal to it. He distinctly states that the peculiarities of lymph spaces in the connective tissue of the so-called scrofulous animals and men are not observable in the perivascular lymph spaces. He also most positively states that it is just in the perivascular lymph spaces that not only secondary miliary tubercle, but also primary tubercle, originates, and this is a well-known fact, of which every pathologist is cognizant. What then has an assumed peculiarity of lymph spaces in a tissue not subject to tubercule, to do with the etiology of the formation of tubercles in a location where the lymph channels are unobstructed, and where, by Dr. Formad's own admission, they appear the same in the scrofulous as in the non-scrofulous?

Furthermore, Dr. Formad mistakes, in his the-

ory, a predisposing for an exciting cause. When he shall have demonstrated beyond the possibility of doubt, this assumed peculiarity in the anatomy of the scrofulous, nothing more will have been done than an explanation given of the well-known *predisposition* certain animals and men have towards tuberculosis. Such a peculiarity could only enhance the power which the *exciting* case of tuberculosis may have, by making its work more easy. It certainly would favor, not antagonize, the action of the tubercle bacillus.

Are a Physician's Carriage and Harness "Tools of his Occupations?"

A suit of considerable importance, especially to country physicians, was recently tried in New Hampshire. The question at issue was whether a physician who was in debt could keep from his creditors his carriage and harness under the provisions of the statute, which exempted from execution tools of a person's occupation. The decision was as follows:

"The court cannot say, as a matter of law, that a wagon or a harness is a tool of a physician's calling, and so exempt to all physicians, nor can they say that it is not such a tool. The most that can be said, as a matter of law, is that it may be a tool of his profession, if, in the particular case, it is reasonably necessary for him to use it as a tool. If it should appear that his practice was confined to his office, or that he was a physician or surgeon in a hospital, attending to no cases outside of the institution, or that he was a surgeon on shipboard, or that he went on foot, or on horseback, or on the cars, to visit his patients, a wagon and harness would not be exempt under our statute, because they would be of no use to him as tools in his practice.

"They might be of use to him in other respects, as in going to church, or in carrying his children to school, or in visiting friends, or as a means of recreation and pleasure; but these uses are manifestly not within the legitimate scope of the technical duty of a physician. Not coming within the strict definition of the term tools, and not being reasonably necessary as tools for him in his practice of his profession, they would not be tools within the meaning of the statute, and so would not be exempt as such.

But if it should be found that the physician claiming the exemption could not practice his profession with reasonable success without a team with which to visit his patients—that he was located in a country town, for example, where it was necessary for him to ride a large part of the time in order to accomplish anything professionally—a wagon and harness might properly be found to be reasonably necessary for him as tools of his occupation. But the finding would be one of fact, so far as the reasonableness of the use is concerned, and it could not be said that these articles are exempt to every physician, or to physicians generally, but only to the debtor in the particular case. If there is any doubt whether an article claimed to be exempt from attachment is a tool under the Statute, the question should be submitted to the jury whether its use as a tool by the debtor in his business is reasonably necessary. If it is, it is exempt; otherwise, it is not exempt."

Nurses in Pest-Houses.

A recent case in a New England State touched on the authority of health officers to employ nurses, at the expense of the town, to attend on persons committed by them to the pest-house, and the court said:

"Having power to compel the confinement of infected persons and prevent their communication with others, and having exercised this power, it became their duty to provide for the wants of those confined there.

"They could not shut them out from communication with their friends and with the world and deprive them of any means of obtaining assistance, and at the same time lawfully withhold necessary support and care.

"They could not establish a hospital without ordinary hospital accommodations, and they could not make the hospital a place of involuntary confinement, and escape the duty of supplying the reasonable wants of those who by confinement and seclusion were prevented from applying to any one else for relief. They could not furnish relief against the will of those confined, and afterward recover the expense from them or from those liable in law to support them. If the health officers were obliged by law to confine persons infected with dangerous diseases, and it was their duty to nurse and support them, and if they could not recover the reasonable expense from them or their guardians, they would be remediless unless they could charge the expense upon the city. The law does not require the performance of a duty, and at the same time withhold the means reasonably necessary to its performance."

A Bar to Malpractice Suits.

A case tried not long since in one of the Western States brought up the question whether a successful suit by a physician for the value of his services did not bar any subsequent suit by the patient for malpractice, and it was held that it did. The first suit was litigated to decide the point of the value of the services, and although the charge of malpractice was not directly made as in the second suit, yet if there had been any malpractice there would, of course, have been no value to the services. The failure to make the charge in the first suit was held to forever prevent its being raised afterwards.

Capital Punishment in Delaware.

The Governor of Delaware not long since deprived a criminal under sentence of death for the long term of *fifty-six* years. The law of the state forbade the commutation of death sentences, but permitted reprieves. There seemed to be some mitigating circumstances in the case in question, and the Governor wished to exercise clemency, but could not under the law, except in the way stated. The case may have been a deserving one, but the method adopted was certainly a palpable evasion of the Statute.

Items.

—An unknown country editor sarcastically remarks: "If many people knew how to pay their subscriptions as well as they know how to run a newspaper, editors would have an easier time of it."

—In the *Columbus Medical Journal*, May, 1884, Dr. B. M. Ricketts reports a case of scarlet fever resulting in abscesses of the neck and elbow joint, with ankylosis, perforation of right tympanum, and total destruction of right cornea.

—Prof. Voltolini, in Breslau, has often noticed that discharge from the ear was followed by tubercular phthisis of the lungs, and *vice versa*. He has recently examined the discharge, and discovered bacilli in it, a proof of the causal connection.

—At the Berlin University are at present matriculated (having either the certificate of the gymnasium, or passed the necessary examination regarding their classical education), 4635 students; of these, 898 study medicine, and of these 180 are from Berlin, 27 from Russia, 22 from America, and 7 from Japan.

—Of the physicians who died during 1883 in England, the *Lancet* mentions these 35 as having reached a high age as follows: Two 95, two 94, two 92, one 91, two 90, one 89, three 88, three 87, five 86, two 85, three 84, four 83, one 82, and four 80, while a far larger number lived more than 70 years.

—According to a report in the *Wratsch* (transl. Physician, a Russian weekly medical paper), on November 28, last year an epidemic of cholera broke out in the girl's Puschkin-school in Moskau. Within fifteen minutes eighteen of the girls were seized by the disease, which, however, soon disappeared. It probably was hysteric in character.

—Prof. Henoch, the celebrated authority on diseases of children at the Berlin University, has demonstrated the occurrence of kidney complication in varicella, and published four cases in evidence. It may be better to pay the same attention to children suffering from varicella, as is done to those attacked by scarlatina, *i. e.*, keep them in the room, and guard them against chilling of the skin.

—The following report shows the value of ostrich farming going on in Southern California: "The ostriches on the Anaheim farm laid 305 eggs during the season from the 1st of May last until the 1st of October. The birds have been plucked twice since their arrival on the farm. The first clip, in May last, yielded \$500. The clip in December yielded 2,500 quills of all kinds, from 18 birds, and is valued at \$1,000.

—Vomacka gives the following directions for the preparation of a substitute for blue ointment, which also keeps better: One part of soft and perfectly neutral potash soap is mixed with a little glycerin in a glass mortar, and one part of mercury is added with constant trituration. When no globules of mercury are any longer visible, add two parts more of potash soap to make four parts. It may be scented with lavender or other essential oil.

—At a meeting of the Alumni of Jefferson Medical College held to take action respecting the

death of Dr. J. Marion Sims, the late Prof. S. D. Gross said, "This man died poor." Thus it appears that this man, the most courted of any doctor that ever lived, by all classes, among the noble and crowned heads, died poor. What shall he expect who lives his professional life among the operatives of farms, factories, stores, etc. Can he expect to die richer than one who had for his services any sum he might ask? Truly, the practice of medicine is a poor business, whatever may be said of it as a profession.

—Prince Carl Theodore, of Bavaria, who graduated as M. D., and has gained well-merited local reputation as an eye physician, was recently honored by the University of Munich, which gave him the honorary doctor diploma. Prinz Ferdinand of Bavaria has also finished his medical studies, and passed his examination as M. D. Both having also passed the German State's examination, are legally entitled to practice. The older, Carl Theodore, has become widely known by the publication of a work on the comparative anatomy of the tongue, which is an evidence of deep learning—it is said that he wrote the work under supervision of Prof. Rüdinger.

 QUERIES AND REPLIES.

EDS. MED. AND SURG. REP.—

Is com. tinct. avena sativa, as found in the shops, what it purports to be, viz.: a pure tincture of common oats? If so, was it not *mistakenly* omitted from the last revision of the Pharmacopœia? I have known a number of sufferers from painful nervous disorders to be much relieved by it. Is any sophistication of a narcotic nature known to be practiced in its preparation? A DOCTOR.

 MARRIAGES.

BARNES—SAINT.—At the residence of the bride's parents, Sharpshurg, Allegheny county, Pa., on Thursday morning, April 24, 1884, by Rev. S. M. Bell, assisted by Rev. W. M. Eaton, of Washington, Pa., Samuel S. P. Barnes, M. D., of Massillon, Ohio, and Emily J., daughter of James Saint, Esq.

HARE—PEMBERTON.—In this city, Thursday, May 8, 1884, Dr. Hobart Emory Hare and Rebecca Clifford, daughter of Clifford Pemberton, Esq.

HAYS—HOLEMAN.—At the residence of the bride's father, in Louisville, May 13, 1884, Dr. H. H. Hays, of New Liberty, Ky., and Miss Anna W. Holeman.

HINKLE—CAMPBELL.—At Arch Street Presbyterian Church, May 19, 1884, by the Rev. John S. Sands, Dr. Frank Whitehill Hinkle, of Buffalo, and Kate Allen Campbell, of Philadelphia.

 DEATHS.

BLAUVELT.—In New York, Saturday, May 17, 1884, Jas. F. Blauvelt, M. D., in the sixty-first year of his age.

FLAGG.—At Yonkers, N. Y., May 15, 1884, L. W. Flagg, M. D., aged sixty-seven years.

HARLEY.—In Cincinnati, Ohio, May 16, 1884, Dr. E. T. Harley.

HIBBARD.—At Elizabeth, N. J., May 17, 1884, of apoplexy, Dr. Rufus F. Hibbard, in the eightieth year of his age.

HUNTER.—At Macon, Tenn., May 12, 1884, Dr. George Alva Hunter, brother of R. E. Hunter, of Memphis, in the thirty-seventh year of his age.

ROGERS.—In Sparta, Ga., May 14, 1884, by lightning, Dr. Wilbur J. Rogers.

TINDALL.—In Aberdeen, Miss., May 15, 1884, Dr. John L. Tindall, over forty years in the medical profession.

LECTURE.

PLASTIC SURGERY.

BY PROF. A. C. POST,
Of New York.

Delivered before the Hudson Co. (N. J.) Medical Society.

Reported by J. A. EXTON, M. D.

At the meeting of the Hudson County Medical Society of New Jersey, held April 1st, in Jersey City, after the regular business was finished, Prof. A. C. Post, of New York, delivered a very interesting and instructive lecture, illustrated by diagrams, photographs, etc., showing the results of rhinoplastic, blepharoplastic, cheeloplastic and heteroplastic operations in plastic surgery.

Prof. Post said by the term plastic surgery was understood the branch of the healing art which aims to supply deficiencies on the surface of the body, resulting from congenital malformation, from traumatism, or from disease. The term plastic is derived from the Greek verb *πλασσω*—I form.

Plastic operations consist in the detachment of flaps from neighboring or distant parts, and uniting them with the surface and edges of the vacant space which is required to be filled. The term anoplastic is sometimes employed, the prefix *an* signifying up, and the term implying the forming or building up of the parts to their proper level.

The term autoplastic conveys the idea that the transplanted parts are derived from the patient himself. The term heteroplastic signifies that the new tissue is derived from another person, or from an inferior animal. Blepharoplastic operations are those which are performed to repair de-

fective eyelids. Rhinoplastic operations are for defects of the nose. Cheeloplastic for those of the lips. Prosopoplastic, for those of the face in general.

In most of the operations for the repair of lost or defective features, the transplated flap is best attached by some part of its circumference to the part with which it was naturally connected, until it has acquired a vital union with the part to which it is artificially attached. The portion of the flap which retains its natural connections is called its neck or peduncle.

There are three methods of transplanting pedunculated flaps, known as the Italian, the Indian, and the French methods. Plastic operations were performed by the ancient Egyptians, Greeks, and Romans. In modern times Branca performed rhinoplastic operations in Sicily in 1442.

In 1597, Jaspas Sagliacossi, professor at Bologna, published at Venice a book entitled "*De Curto-rum Churgia per Insitionium*." In this book he gave a detailed account of his operations for the restoration of lost noses and other features. This book acquired a world-wide celebrity. This mode of operating consisted chiefly of the transplantation of flaps from the integument of the arm, the hand being bandaged to the head during the process of union. Fabulous accounts of his operations were published, representing the excision of flaps from a poor man's nates to supply the deficiency of a rich man's nose, and it was asserted that the vitality of the new nose depended on the life of the person from whom it was taken. A story is related of a nobleman whose nose was formed from the integument of a Florentine peasant, and which retained its vitality for a number

of years. Suddenly, without any obvious cause, the nose died and became a putrid mass. On inquiry, it was ascertained that the death of the nose coincided with that of the peasant from whom the material for its construction was obtained.

Butler, in his "Hudibras," alludes to such fabulous rumors, when he writes:

"Thus learned Taliacotius, from
The brawny part of portus bum,
Cut supplemental noses, which
Would last as long as parent breech,
But when the date of Nock was out,
Off dropped the supplemental snout."

The mode of repairing defective parts by transplanting flaps from remote regions is called Italian or Talicottian method. The mode of operating by transplanting flaps from adjacent parts, and twisting the peduncle so as to bring the flap into its proper position, is known as the Indian method, having long been practiced in Hindostan, and having been made known to European surgeons about the close of the eighteenth century.

It had long been the custom of the native tyrants of India to mutilate their rebellious subjects by cutting off their noses, and as "necessity is the mother of invention," the persons who were mutilated exercised their ingenuity in finding a remedy for the disfigurement resulting from the mutilation. The operation for this purpose was not performed by physicians or surgeons, but by a class of artisans who were engaged in pottery. The Indian operation for the restoration of lost noses consisted in freshening the edges of the space from which the nose had been excised, and cutting a flap from the integument of the forehead, and twisting its peduncle so as to bring the flap into the position of the nose, and fixing it so as to secure union with the adjacent parts.

The same principle is applicable to the restoration of other features besides the nose. The Indian operation of rhinoplasty was performed in London in 1803, but the first operation was unsuccessful. The first successful operation in Europe was performed in London by Mr. Corpue, in 1814. The operation has since been performed many times by surgeons in different parts of Europe and America. The result of the operation has been quite satisfactory, when enough of the original nose has remained to support the transplanted flap in its new position. But in cases in which the nose has been entirely destroyed, the new organ is an imperfect substitute for the old one, presenting a flattened or depressed appearance. But even in these cases, the new nose

is a decided improvement on the cavernous depression which preceded its formation. The French method of performing plastic operations consists in cutting flaps in the vicinity of the defective part, and gliding them into position without twisting the peduncle to any considerable extent.

The Italian method of restoring lost features, by transplanting skin from remote parts, is now very seldom resorted to, except in those cases in which there is no available material in the immediate neighborhood.

The Indian method is often employed, and yields very excellent results. In many cases where the nose or the eyelid is the feature to be repaired, it is the only available method. The French method, by gliding the flap into place without twisting its peduncle, is the best operation in cases in which it is applicable, especially in supplying deficiencies of the lips and cheeks. The principal difficulty to be contended with is the tension of the flap, when it is brought into its new position. This difficulty may, however, in most cases be obviated by giving a decided curve to the peduncle of the flap. In the performance of plastic operations, certain facts have been observed, to which it is proper to direct your attention. On making the *first* incision, the flap becomes pale, but afterwards the parts adjacent to the connecting medium assume a redder color. Dark bluish spots or streaks are often found scattered through the flap. Blood spouts at first from the arteries at the edges of the flap, and afterwards fibrine is effused. The flap contracts considerably, and is disposed to turn inwards; it also acquires an increase of thickness. These changes are most distinctly perceptible in young persons of healthy constitution. The flap loses all sensibility, except at the extremity by which it is nourished, and even there the sensibility is but slight. The flap should be one-fourth or one-third larger than the space which it is designed to fill, and a wide bridge should be left, connecting it with the adjacent part. The flap should contain not only the skin, but a considerable thickness of the subjacent parts, so as to afford a good vascular supply. It is highly important that it should be easily held in position, as any considerable tension will be likely to hinder its adhesion to the adjacent parts. In cutting the flap, it is well to make a pattern of oiled silk or other suitable material, of the size and shape of the space to be filled, and to use the pattern as a guide in making the flap.

In fixing the transplanted flap in its new posi-

tion, one or two pin sutures may be advantageously employed. These should include nearly or quite the whole thickness of the flap, and the points of entrance and exit of the pins should be at least eight or ten millimetres from the edges of the wound. Numerous sutures of fine *black silk* should be employed to secure a perfect apposition of the edges of the wound. The spaces between the sutures should not exceed two or three millimetres. Black silk is preferable to white, as being less irritating, and being more easily seen. The fineness of the silk is indicated by the letter O on the spools. In introducing the sutures, if the edges of the wound are of unequal thickness, the needle should be introduced more superficially on the thicker side.

Before closing the wound, it may be freely irrigated with a solution of mercurial bi-chloride, eight grains to the pint. After applying the sutures, there is no occasion for applying bandages or plaster, but the surface may be freely exposed to the air. When the flap is congested, cold-water dressings may be applied. On the ninth or tenth day, all inflammatory swelling has generally subsided, and the cuticle cracks and peels off. When the flap has been taken from the hairy scalp, the hairs, after a time, will grow, and they may, from time to time, be plucked with forceps. The growth of the hair may be diminished by the free application of lime-water, or of a solution of bi-chloride hydrate. Or the hair-bulbs may be destroyed one by one by a galvanocautery.

In blepharoplastic operations, when the eyebrow has been destroyed, it may be replaced by a flap from the hairy scalp, the hairs being allowed to grow over the space corresponding with the eyebrow, those above and below being plucked or destroyed. When I first restored the eyebrows in this way, I supposed that the practice was original with myself; but I was afterwards informed that I had been anticipated by Dr. Pancoast, of Philadelphia.

To give proper shape to the newly-formed feature, it is often necessary to excise here and there small portions of the newly-transplanted integument. This may be done without hesitation, as wounds in recently transplanted integument heal by the first intention and with great rapidity; much more so than wounds in other parts. This observation is made by Dieffenbach, and I have often verified it in my own practice. When these wounds are allowed to granulate, they bleed freely at first, and the blood is very bright and liquid; the wound appears pale, and the edges

are scarcely inflamed; there is little or no suppuration, and the exuded blood forms a scale or scab which after awhile falls off, leaving the wound healed.

When it becomes necessary to separate the edge of the flap from its new attachment, it never heals by the first intention, but always goes through a tedious process of granulation. Sensation is very slowly developed in transplanted parts. Many months, for example, elapse before a new nose, transplanted from the forehead, becomes sensible to pain. Sensibility is first restored near the line of union with the adjacent parts. The newly-formed feature does not begin to perspire, nor to form thick pus when wounded, before twelve months. There is much difference in different cases, in the power of withstanding cold possessed by the transplanted part. A patient, for whom Dieffenbach made a new nose, was attacked with jaundice eighteen months afterward: the whole body, with the exception of the nose, was of a deep yellow color when the patient was warm; the nose was white. When he was cold it was of a dark bluish hue.

The treatment of the cicatricial contractions is a matter of great importance. It is not safe to include cicatricial tissue in flaps which are to be transplanted, or to raise it to any considerable extent from the subjacent parts, as it almost invariably sloughs when it is so treated. But it may be freely divided, and the flap of healthy skin may be united with its divided margin, with a good prospect of union by the first intention. It may be divided into narrow segments by incisions crossing each other at short intervals, and may then be put upon the stretch, and it will not slough if the sub-basal attachments be not interfered with.

Certain special modes of operating, which have been introduced by different surgeons, are worthy of attention.

Dieffenbach introduced the important improvement in treating the deformity occasioned by the loss of the nasal septum from syphilitic disease, and the sinking of the remnants of the nasal pyramid into the cavity. He made longitudinal incisions dividing the nasal pyramid into five strips, attached above and below, and raised them to their proper position, fixing them with pins and sutures.

T. Wharton Jones, in certain cases of ectropion, made a deep triangular flap, the base of which was formed by the margin of the everted lid, and bringing the margin of the lid into its normal position caused the apex of the flap to recede widely

from the part from which it was taken, converting the shape of the wound from the letter V to Y, and fixing the flap in its new position by sutures. This ingenious operation is applicable to other parts besides the eyelids.

Burow, a German surgeon, introduced a new operation for certain deformities of the lips, in which there is a great deficiency in the lower lip and a relative superfluity in the upper lip, or *vice versa*. He took out a triangular portion from the diseased lip, the base of the triangle corresponding with the vermillion border, and extending on one side to the angle of the mouth; and extending the line of the base by an incision into the cheek, he excised another triangle, with its apex in the opposite direction, and uniting the opposite sides of the two triangles by sutures, restored the symmetry of the mouth, lengthening the shortened margin of one lip and shortening the superfluous margin of the other.

In all cheeloplastic operations, it is important that the margin of the newly-constructed lip should be invested with mucous membrane. When a flap has been transplanted from the cheek, the mucous membrane should be drawn out over the margin and attached to the skin by fine sutures.

When there is no healthy mucous membrane for the purpose, the skin itself may sometimes be inverted over the margin.

Within the past fifteen years a new mode of supplying deficiencies of integument upon the surface of the body has been introduced, viz.: transplanting thin portions of skin without peduncles upon recent wounds, or upon granulating surfaces, and maintaining them in position by plasters and bandages. The name skin-grafting, or epidermic grafting, has been applied to this process. It is somewhat analogous to the process of budding or grafting fruit trees. The practice was introduced by Reverdian, a French surgeon, in 1869. Reverdian was at that time Interne in one of the French Hospitals. He shaved off very thin portions of integument of the size of a grain of rice, and applied them with their raw surfaces to the denuded or granulating surface of the part which he wished to invest with new skin. Close apposition was maintained for a number of days, and on removing the dressings, it was found that some of the grafts had acquired a vital union with the surface upon which they had been placed, and from each one of these points there was a radiated growth of new skin. This has now become an established practice in surgery, and it has become a valuable addition to our resources in cases in which there has been an extensive loss of skin.

The practice has been modified by See, Ollier, and Poncet, who successfully transplanted large portions of skin, in some cases larger than a silver dollar.

In grafting portions of skin without peduncles, a very different course is to be pursued from that which is adopted in the transplantation of pedunculated flaps. Instead of including a considerable thickness of subcutaneous tissue, the part to be transplanted should be cut very thin, never including any subcutaneous tissues, and often including less than the whole thickness of the skin.

This mode of grafting has the advantage that it can be applied where there is no available sound skin in the vicinity of the part which is to be restored, and that the new material may be obtained from parts of the body which are covered by clothing, so that the patient will not be disfigured by the cicatrices which follow the excision of the flaps. On the other hand, it has the disadvantage that it does not provide a flap of considerable thickness, such as is required for the restoration of the lips, where the skin must be lined with mucous membrane, to perform its function in a satisfactory manner. The operation is a useful one under some circumstances, but it is not likely to supersede the transplantation of pedunculated flaps.

COMMUNICATIONS.

THE TIME REQUIRED BY THE BLOOD FOR MAKING ONE COMPLETE CIRCUIT OF THE BODY.

BY ROBERT MEADE SMITH, M. D.,
Professor of Comparative Physiology, University of Pennsylvania.

(Continued from page 681.)

The following are the details of two experiments made on this plan:

Experiment 1.—Nov. 24, 1883. Dog. Weight 18 kilo. Experiment conducted as described above; effects of ether had largely passed off before the experiment was made. Time required for pigeon's corpuscle to pass from the left to the right jugular, 20 seconds. Pulse in 20 seconds = 55.

BEFORE INJECTION.

Blood pressure.	Pulse in 15 Sec.	Respiration in 15 Sec.
160 mm.	36	6

AFTER INJECTION.

Blood pressure.	Pulse in 15 Sec.	Respiration in 15 Sec.
5 seconds, 160 mm.		
10 " "	155 "	
15 " "	148 " 39 in first	15 sec. 6
20 " "	135 " "	
30 " "	90 " 43 in second	15 " 6
45 " "	70 " 38 in third	15 " 7

The experiment was then interrupted for half an hour, when the low pressure produced by the pigeon's blood had passed off. One grm. of potassium ferrocyanide was then dissolved in 10 cc. of normal salt solution, warmed to 38° C., and then injected into the left jugular vein, and the blood collected from the right jugular, and other details followed, as in the case of the injection of pigeon's blood.

BEFORE INJECTION.

Blood pressure.	Pulse in 15 Seconds.	Respiration. in 15 Seconds.
155	40	7

AFTER INJECTION.

Blood pressure.	Pulse in 15 Seconds.	Respiration. in 15 Seconds.
5 seconds, 110		
10 " 50		
15 " 30	16 in first 15 sec.	1
20 " 20		
30 " 18	6 in second 15 "	none.
	Dead.	

The blood was then allowed to stand in the watch-glasses until the serum separated; a drop of the latter was then drawn off with a pipette, placed on a porcelain dish, acidulated with dilute hydrochloric acid, and tested with a drop of dilute ferric chloride solution. It was then found that the portion of blood collected *fifteen* seconds after the injection of the potassium salt was the first to form the characteristic blue with the iron. The potassium ferrocyanide, therefore, passed from the left jugular vein to the right in *fifteen* seconds; pulse in 15 seconds = 16.

Experiment 2.—Nov. 30, 1883. Dog. Weight 10 kilo. Details of experiment the same as in the preceding. The pigeon's corpuscles were found in 17 seconds; pulse in 17 seconds = 53.

BEFORE INJECTION.

Blood pressure.	Pulse in 15 Seconds.	Respiration. in 15 Seconds.
120	33	5

AFTER INJECTION.

Blood pressure.	Pulse in in 15 Seconds.	Respiration. in 15 Seconds.
5 seconds, 120		
10 " 120		
15 " 120	44 in first 15 sec.	6
20 " 120		
30 " 115	50 in second 15 "	7
60 " 60		

The animal was then allowed to remain undisturbed until the pressure again became normal, when 0.4 grm. potassium ferrocyanide, dissolved in 4 cc. normal salt solution, was injected, and the blood collected as before.

BEFORE INJECTION.

Blood pressure.	Pulse in in 15 Seconds.	Respiration in 15 Seconds.
150	36	6

AFTER INJECTION.

Blood pressure.	Pulse in in 15 Seconds.	Respiration. in 15 Seconds.
5 seconds, 120		
10 " 55		
15 " 25	18 in first 15 sec.	2
30 " 15	15 in second 15 "	none.

Heart stopped one minute after injection.

The serum was then tested as in the previous case, and the Prussian blue found in the blood collected 9½ seconds after the injection of the potassium salt. The heart-beats in this period = 14.

The comparison of the times required in the same animal for the circulation of the pigeon's blood and the potassium salt, clearly proves the falsity of the assumption that the salt moves through the vessels with the same velocity as the blood.

Vierordt (*Stromgeschwindigkeiten des Blutes*, Berlin, 1862), who, by his numerous experiments and important modifications and extensions of the plan of research, has identified himself with Hering's method, from a series of seventeen experiments made on dogs with an average body weight of 9.14 kilo., places the mean time of circulation in the dog at 15.22'', and from experiments made on three rabbits of 1.37 kilo. average weight, he gives 6.91'' as the mean time of circulation. In giving these figures, he states that he has been careful to exclude all experiments in which the violent symptoms produced by the injection of the poison occurred within the time that his other experiments made on the same plan, but in which such symptoms did not appear, give as the mean time of circulation. This is, however, manifestly unwarrantable; for, were the substance injected a solid carried mechanically by the blood, any disturbance of circulation accompanied by great reduction in the pulse and blood pressure could only produce reduced velocity of the circulation, and consequently prolong the time required for the circuit of the injected solid around the blood-vessel system. But that in the face of such disturbance, and that, too, of the most violent character, the salt could be distributed with the greatest rapidity throughout the body, clearly proves that it was not mechanically carried by the blood. Thus, in the experiments detailed above, we find that even when given in doses large enough to arrest the heart almost instantly, thus removing the main cause of the movement of the blood, and greatly

reducing its velocity, we find, nevertheless, that the potash salt circulates more quickly even than the time given by Vierordt, and twenty-five per cent. faster than the pigeon's corpuscles are carried by the blood under normal conditions of pulse and pressure; for it should be noticed that the pulse and pressure remain comparatively undisturbed until after the circulation is complete. That the pigeon's cells are not delayed in their passage through the capillaries is proved by the fact that there is never any rise of blood pressure after making an injection of pigeon's blood, as would occur were there any blocking of the circulation in the capillaries.

The following are the results obtained in ten experiments made in the manner described above, to determine the time required for the passage of the pigeon's corpuscles from one jugular vein to the other. In each case the pulse and pressure remained undisturbed until after the circuit was completed.

No.	Animal.	Time of circulation.	Pulse in time of circulation.	Weight.
1.	Dog.....	20 seconds.	55	18 kilo.
2.	".....	17 "	53	10 "
3.	".....	15 "	50	8 "
4.	".....	15 "	47	8 "
5.	".....	18 "	44	10 "
6.	Pup.....	20 "	60	3 "
Averages		17.5 "	51.5	9.5 kilo.
1.	Rabbit....	14 "	—	3 "
2.	".....	12 "	—	11½ "
3.	".....	9 "	27	2½ "
4.	".....	9 "	35	2½ "
Averages		11	31	2.3 "

It is seen, in the above series of experiments made on dogs with about the same average weight as those experimented on by Vierordt (9.41 kilo., and 9.5 kilo.), that the mean time required by the pigeon's corpuscles for the jugular circuit is 17.5'', as compared with 15.22'' obtained by Vierordt for the potassium salt; while in the rabbit, 11'' was obtained as a mean as compared with 6.9''. Consequently, in the dog nearly 15 per cent. of the time stated by Vierordt as expressing the mean time, and in the rabbit over 59 per cent., are due to diffusion.

In this connection it might be suggested that the rapidity of circulation is greater in small animals than in large, not only on account of the shorter path to be traversed, as insisted upon by Vierordt, but because small animals contain, both absolutely and relatively as to body-weight, a smaller volume of blood; and since it has been shown that diffusion has something to do with the result, the salt will diffuse more rapidly into a small volume of fluid than into a large; therefore, the element of diffusion is more marked in the rabbit than in the dog.

2. *The Value of the Infusion Method in Determining the Mean Time of Circulation.*—It may at the outset be admitted, with Hering and Vierordt, that if the mean velocity of the circulation could be determined for the jugular path, it would probably express the mean time required for the total amount of blood to complete the circuit of the body. For while the portion of the blood which leaves the aorta to pass through the coronary arteries to reach the right auricle follows a shorter path than the blood which passes through the capillaries of the feet or the portal system, the velocity in the large trunks is so extremely high that the difference in time in passing through two large trunks, even of such extremes of length as the carotid at its origin and the metatarsal, is so slight as scarcely to be appreciated. The great part of the time of the circulation is therefore consumed in passing through the capillaries, and the jugular path may be regarded as giving a mean between the two extremes of distance above alluded to. It therefore only remains to determine whether the mean time required for the jugular circuit has been or can be obtained by the infusion method, or by the modification which I have employed.

It has already been shown that the elements of diffusion in this method cannot be neglected, since, even after stoppage of the heart, when the only remaining propelling force acting on the blood is the rapidly decreasing difference in pressure between the arterial and venous systems, the potassium salt is carried around the circuit even in less time than is stated by Vierordt to be the mean normal time of circulation, and in considerably shorter time than is required for the pigeon's corpuscles. But even this time required for the circulation of the pigeon's corpuscles is far above what must be the true mean time. For we know that in all cases of movement of fluids in tubes, the portion of the fluid in the centre of the tube moves with a much higher velocity than the portions in contact with the walls of the tube. It is also known that the red blood corpuscles, from their greater specific gravity, are carried in this central column of greatest velocity, and, *a fortiori*, pigeon's corpuscles, having a greater specific gravity than non-nucleated mammalian cells, will have the maximum velocity of the moving column. Consequently, the time required for the circuit of the pigeon's corpuscles will be much shorter than that required for the mass of the blood.

An experiment of Schklarewsky (Hermann, *Handbuch der Physiologie*, vol. iv., p. 315) suggested

to me a means by which the minimum velocity of the blood could be obtained. He found, when particles of different densities suspended in a fluid were propelled through capillary tubes, that the particles with the greatest density moved with the highest velocity, while the lighter particles moved in the peripheral portions of the stream, where the velocity was the lowest. This fact serves to explain the motion of the red blood cells in the axis stream, while the lighter white blood corpuscles move along the walls of the vessels. If, therefore, a fluid containing suspended particles lighter than the red blood disks, and small enough to pass through the capillaries, is injected into the blood current, it may be assumed that the lighter particles will be thrown out of the more rapidly moving central current into the slower moving excentric layers.

The following experiment seems to indicate that this is actually the case:

About 1 gram of carmine was rubbed up in a mortar with 30 cc. of normal salt solution, poured into a conical glass vessel and allowed to stand for twenty-four hours; by this time all the larger carmine particles had settled to the bottom of the glass, and the upper layers, as proved by microscopic examination, contained only carmine granules, of which the largest were smaller than the mammalian red blood cells. This was determined by placing a drop of the carmine fluid with a drop of blood on a slide under the microscope. Ten cc. of this fluid were then injected into the external jugular vein of a dog, and the time which elapsed before the carmine particles appeared in the blood drawn from the opposite jugular vein was determined in the same manner as was made use of in the experiments with the pigeon's blood.

The following are the details of the experiment:

Experiment 11.—Dog. Weight, 10 kilo.

BEFORE INJECTION.

Pulse in 15 seconds.	Pressure.	Remarks.
35	110	

AFTER INJECTION OF 10 CC. OF CARMINE FLUID.

36 in first 15 seconds.	110	Carmine granules found in
36 in second 15 "	115	blood drawn from opposite
37 in third 15 "	118	jugular in 35 seconds after injection. Pulse in 35 seconds=85.

Without laying too much stress on this single experiment, it is at any rate probable that a mean between this extreme and the maximum velocity shown by the pigeon's corpuscles will give the mean time of the circulation. Consequently, I would place the average time required to complete the circulation in a dog of 10 kilo. weight as between 25 and 30 seconds. It will be seen that

this statement can be confirmed by another line of argument.

If the amount of blood driven out of the left ventricle was a constant quantity, the rapidity of the circulation would be in direct ratio to the number of pulsations of that organ. But as we know that the amount of blood thrown out of the heart at each contraction is subject to great variability, and as I have shown in the paper before alluded to that this amount falls considerably below the estimate of the ventricular capacity made post-mortem, the attempt of Vierordt to formulate a law as to a definite relation between the duration of the circulation and the number of ventricular systoles which would agree with the numbers obtained by him as expressing the time of the circulation, is not warranted by the facts in the case.

Thus, Vierordt stated that in all species of animals the time required for the completion of the circulation was the time required by the heart for making *twenty-seven* pulsations; consequently, each ventricular contraction must discharge $\frac{1}{27}$ of the entire bulk of blood in the body.

Now, according to the calculations of Heidenhain, which are generally accepted as correct, the average amount of blood in a dog is $\frac{1}{8}$ of his body's weight. A dog weighing 10 kilo. will, therefore, contain 769 grams of blood; or as the specific gravity of the blood is about 1050, 730 cc. of blood. To propel this volume of blood once around the body in twenty-seven pulsations of the heart, at each contraction the ventricle must discharge 27 cc. of blood, a quantity which is about double the amount which the ventricle of a dog weighing 10 kilo. can be made to contain.

There can be no doubt, however, though the statements of Vierordt in this connection are incorrect, that there must be a definite relation between the number of heart-beats and the time of circulation; for the application of the same line of argument to the data I have obtained gives a result which almost absolutely coincides with the figures obtained by direct measurement. In a dog weighing about 10 kilo., about 12 cc. would be thrown out of the ventricle at each contraction under normal respiration; and as the amount of blood in the body would in a dog of this size be 730 cc., sixty pulsations of the heart would be required to drive the entire amount once around the body. Placing the pulse-rate at 120 in the minute, the circulation would be completed in 30 seconds, a number which is identical with the figures given above.

It also appears that the number thus obtained

by deduction as giving the number of heart-beats to complete the mean circulation is nearly in accordance with the number of pulsations required for the circulation of the pigeon's corpuscle; for if 50 pulsations are required for the maximum velocity and 85 for the minimum, the mean between these, 67, is near enough to the figure obtained by deduction to show that the method is nearly absolutely correct.

While there can be no doubt that an abnormal increase in the rate of the pulse, by diminishing the amount of blood thrown out of the ventricle, will lengthen the time required by the blood to complete the circuit of the body, it cannot be urged that in my series of experiments the pulse was sufficiently accelerated by the ether to cause any retardation of the circulation. For in experiment 1, where the effect of the ether had passed off before the estimate was made, the time of circulation was even longer than in cases in which the narcosis was more profound.

There is one other point in which my experiments fail to confirm the results obtained by Vierordt. Although I cannot find in his paper before referred to any experiments to substantiate the assertion, he makes the statement (*Grundriss der Physiologie des Menschen*, 5te Auflage, 1877, S. 162) that moderate stimulation of the vagi lengthens the time of circulation by reducing the number of pulsations of the heart, but that nevertheless 26 contractions are here also required to complete the circuit; from which he makes the deduction that moderate irritation of the vagus reduces the number of the heart's contractions without modifying the amount of blood thrown out at each systole.

Of course, since I have not seen the details of the experiments on which these conclusions are based, it is impossible to form any opinion as to what is meant by "moderate" stimulation of the vagus.

As far as I know, no measurements of the quantity of blood thrown out from the heart during vagus irritation have ever been made, though a diminution of pulse-rate by cold has been found by Howell and Donaldson (*Proc. Roy. Soc.*, No. 226, 1883,) to augment the quantity of blood discharged at each systole. And if the irritation was not sufficiently severe to cause much reduction in blood-pressure or velocity, it is conceivable that the pulse might be considerably reduced in frequency, but that the reduction would be balanced by the larger volume of blood discharged at each contraction. The only difference, therefore, in the phenomena of circulation during

vagus irritation from the normal condition, would be that fewer heart-beats would be required to complete the circulation. The following experiments show this to be the case:

Experiment 12.—December 18, 1883. Dog. Weight, 11 kilo. Pigeon's blood injected, and time of circulation estimated as before. Irritation of vagus with induction current commenced at moment of injection.

BEFORE INJECTION.

Pressure.	Pulse in 15 seconds.	Respiration.	Remarks.
180 mm.	37	5	

AFTER INJECTION AND VAGUS IRRITATION.

140 mm.	16 in first 15 seconds.	Vagus irritated 31	
150 "	20 in second 15 "	seconds. Corpuscle found in 19	
140 "	32 in third 15 "	seconds. Pulse in 19	
120 "	48 in fourth 15 "	seconds = 21; normal pulse in 19 seconds = 50.	

Experiment 13.—December 20, 1883. Dog. Weight, 14 kilo. Conditions of experiment the same as in preceding.

BEFORE INJECTION.

Pressure.	Pulse in 15 seconds.	Respiration.	Remarks.
160	35	7	

AFTER INJECTION AND IRRITATION.

140	18 in first 15 seconds.	Vagus irritated 44 seconds.	
160	24 in second 15 "	Corpuscle found in 14	
130	30 in third 15 "	seconds. Pulse in 14 seconds = 17. Normal pulse in 15 seconds = 35.	
90	47 in fourth 15 "		

HOSPITAL REPORTS.

NEW YORK HOSPITAL.

CLINIC OF PROF. WILLIAM H. DRAPER.

Reported by W. H. SEELYE, A. M., M. D.

Pneumonia.

The patient is a native of Canada, 29 years of age, married, and a porter by occupation. Was admitted to the hospital last evening. There is no family history bearing on his present illness. He has never had syphilis, rheumatism, or malarial fever. Is temperate in the use of alcoholic liquors. He was in good health until a week ago last Tuesday, when he took cold, and suffered from soreness and a sense of oppression in the left side of his chest. He went about, however, until last Friday, December 23d, when he had a severe chill, after which he felt very ill. Then he had a cough which was accompanied by a glairy, viscid, mucous expectoration, and continued soreness over the left chest and shortness of breath. Since then he has had ardor-urinae, and he passes his water frequently and in small quantities. He suffers constantly from anorexia, and he has pain and tenderness extending all over the left chest and about the epigastric region and radiating towards the left groin. He went to a physi-

cian outside, who applied a mustard poultice over the lower part of the chest, and told him to wear an oil-silk jacket, and he said that he had either a pleurisy or a pneumonia. On his admission the dyspnoea, pain, and cough were very intense; and his pulse was 118, respiration 24, and temperature 103.6. His urine contained no albumen or casts.

Inspection.—There is marked dyspnoea and a loose cough. The shoulders and back are covered with a profuse acne eruption, which was produced by the oil-silk jacket. The face is flushed and dark.

Palpation.—The movements of expansion and elevation of the chest are lessened upon the left side, and the vocal fremitus is a little more marked. There is great sensitiveness of the skin, and tenderness upon pressure over the whole of the left side.

Percussion.—Over the left chest anteriorly dullness extends from the fifth rib downwards to the base of the lung. It extends a little higher up in the axillary region, and posteriorly it covers the whole area of the left chest below the spine of the scapula. Pulmonary resonance is normal on the right.

Auscultation.—Broncho-vesicular respiration and bronchophony are heard over the whole of the left chest. The first sound of the heart is feeble.

The history of this case, gentlemen, is not a perfectly clear history of a pneumonia beginning at the time of his first illness, but it is similar to another case you saw here a short time ago, where there had been a previous illness before the acute attack. This man was first taken ill two weeks ago with a cough and a sense of soreness and oppression in the left chest; but he kept about until last Friday, coughing and complaining of malaise. Then he had a chill, which was followed by a sharp pain in the side, referred to the region of the umbilicus, and a difficulty in breathing. He went to a doctor, who told him to wear an oil-silk jacket; and he applied a blister to his chest and told him that he had either pleurisy or pneumonia. And the history since then has been the history of a pleurisy or of an acute pneumonia. Last evening, upon his admission, he was in great distress from oedema of the lungs which demanded immediate attention. After he was relieved by treatment, a physical examination was made, and the same signs were found as we have obtained to-day. These are signs of consolidation of the lung, but modified in such a way as to give one a suspicion that they may be due to a pleurisy. Over all the region of dullness there was obtained, not a distinct bronchial respiration, such as is heard in pneumonic consolidation, but rather a distant broncho-vesicular murmur with bronchial voice. But neither the respiratory nor the voice sounds were so distinct as in complete consolidation of the lung. It was thought, therefore, that there might be fluid in the pleural cavity, and so a hypodermic needle was inserted to determine this; but no fluid was found. Hence I conclude that the physical signs denote the existence of a circumscribed limited pulmonary consolidation, rather than a pleurisy, with effusion confined to circumscribed limits. We sometimes see cases of pleurisy where the effusion is confined within certain limits by

the formation of fibrous adhesions between the costal walls and the pleura of the lung, and thus we get a circumscribed pleuritic effusion of serum, or it may be a pleuritic abscess. And the reason that it was thought that this might be a case of pleurisy, with a circumscribed effusion, was because of the absence of the usual auscultatory signs found in cases of pneumonic consolidation. But of course the failure to find any fluid is the crucial test.

This is evidently not a case of ordinary croupous pneumonia, but in its origin and history it is very similar to a case which you saw in another ward some time ago, where there was a period of preceding symptoms just as there was here. These were symptoms of a bronchitis which was neglected, and so ran on into a catarrhal pneumonia, which ran a limited course and terminated on the eighth or ninth day, and which was severe in degree. This man since he came in has had a temperature of nearly 104°, and to-day at 12 o'clock it was 103.8°, but it has now fallen to 103.2°, with a pulse of 120, and respirations 24. The expectoration is rather that of a bronchitis than a pneumonia. And in fact the consolidation of the lung tissue here is not as absolute as in croupous pneumonia, but it is a condensation produced by a partial filling of the air cells.

Since this man came in he has been a good deal oppressed for breath, and his breathing is labored and his face becomes red, and I doubt not he suffers constantly from that most distressing sensation, a want of breath. The reason of this is that the breathing space is much impaired, and he probably does very little breathing with the left lung, but most of it with the right. The cough and respiration are such as indicate a pretty intense congestion, giving rise, I have no doubt, to an oedematous condition, perhaps of both lungs. His pulse is good, not strong, but regular, compressible, and rather feeble; and the first sound of the heart is feeble. Now, when you take into consideration the character of his breathing and of his pulse, it is evident that these symptoms demand special attention. The heart needs to be stimulated in order to help it to overcome the pulmonary obstruction. So he is now being stimulated with alcohol and digitalis, and he has been taking one ounce of whiskey and ten drops of the tincture of digitalis every two hours, and he has also been cupped over the chest, so his breathing is now a great deal better than it was. His mind is perfectly clear, and his brain seems to be well nourished, and there is no delirium, and on the whole he is doing very well. But the case demands very strict and watchful attention, for if such cases are watched with great care and attention you will frequently save life. They are not cases to purge and bleed, and to treat upon the old antiphlogistic plan. You cannot shorten the duration of the disease, but you must support the patient, and watch him while he goes through with the regular course of the malady. This has been called "expectant treatment," but in the strict sense of the word it is not truly such; for you are not waiting for the disease to cure itself, but you are watching for such emergencies as demand the attention of the doctor, and these are almost always of the nature of embarrassment from a feeble circulation. A good deal can be

done for his relief by cupping; and repeated successive dry cuppings, with alcohol and digitalis, and with opium, if there is much restlessness, pain, and discomfort, will constitute the armament which you are to use in guiding the patient safely through.

There is one point in the history which is suggestive. He refers his pain to the region of the umbilicus. Many cases of pleurisy have been mistaken for colic because of this location of the pain. It is not at all uncommon when a pleurisy is in the lower portion of the chest, to refer the pain to some point in the upper abdominal region, or even lower than the umbilicus; and so it may be sometimes mistaken for a peritonitis, as well as a colic. There is one other error which is sometimes made in the diagnosis of a pneumonia, though not in adults as a rule. But it not infrequently happens in children that a pneumonia is mistaken for inflammation of the brain. In children of from three to ten years of age, an attack of pneumonia is often ushered in with convulsions, delirium, and cerebro-spinal symptoms, and therefore your attention is likely to be drawn entirely away from the chest. You should remember this fact, and be on the lookout when you find these symptoms in a child. He may not complain of any pain in the chest, and he may not have any cough, but there will merely be cerebro-spinal excitement to show the onset of the disease.

This patient is now complaining of the insomnia of fever, which is sometimes very distressing, or perhaps it is here more the insomnia which not infrequently accompanies those conditions which necessitate constant attention to the breathing, which, if not automatic, requires a great deal of attention. This occurs in cardiac dyspnoea and in pneumonia, when the patient is "almost dead for sleep" as they often express it; but as soon as they fall into a doze they are aroused immediately from lack of breath; and they have to keep on the alert all the time, so that they can not lose consciousness long enough to procure any refreshing sleep. It will not do here to give a very large dose of opium, which would diminish the sensibility of the respiratory centres; but the wisest plan is to stimulate the heart, and at the same time to give moderate doses of opium. Digitalis is a very valuable remedy for this dyspnoea, because it allays the irritability of the respiratory centre, and supplies it more thoroughly with blood. And opium combined with digitalis will produce better effects than opium alone.

In connection with this case I would like to make some remarks upon the subject of feeding in acute diseases. With this man nausea has been a troublesome symptom, and so he has been able to take food in small quantities only.

In many cases of pneumonia this embarrassment does not exist, and in many other cases of acute illness it does not. Now, while I believe that in some instances patients suffering from acute diseases may suffer for the want of food, yet I believe that in many more instances they are forced to take food unnecessarily. The tendency in the last twenty-five years has been to feed and stimulate very largely, and I think that food has been too much crowded oftentimes, and that injudicious feeding is not rare in the management of acute diseases. You probably all know pretty

well from personal experience how the stomach rebels against food if you are not feeling well, and how hard it sometimes is to persuade yourself to eat. Now, while I do not believe it is safe to yield absolutely to this objection to food, yet I do think it is dangerous to push the food too far, and to make a patient take it if he does not want to, beyond a certain point. It has recently been demonstrated pretty clearly that a man in perfect health can starve himself for a good while without suffering any injury; and I do not believe that a little judicious starving in acute diseases is injurious, and at all events it is better than crowding the food. The proper method is to give food in small quantities, and at not too short intervals; and it should be of the most nutritious quality, and given without consulting the taste or the whims of the patient. The majority of cases should be fed with milk, and the preparations of meat, and animal broths; and they should take no solid food, or but very little. There is a great tendency nowadays to feed these patients with farinaceous foods, and gruel, and upon what is called a sick diet; and this is very mischievous, because it gives rise to a fermentative dyspepsia, which is an additional source of suffering, and oftentimes it becomes a serious complication. Gruel, farinaceous substances, and sweets should be carefully avoided; and the strictest directions should always be given as to the kind, quality and quantity of food, as well as of the medicine. And the patient should be allowed no latitude, but should be made to take the food just as it is ordered. And I think there is no more important function, on the part of a doctor, than to insist with the most absolute strictness upon the kind, quality, and amount of food to be given to a sick person. And you will often find that a great deal of mischief has been done in your absence, from a failure to impress upon the attendants the importance of the food.

Patients, as a rule, are no longer treated in private practice as they used to be, but hospital methods and discipline are finding their way into the homes of the sick, as they should. The management of the patient was formerly left to the nurse and attendants, and the doctor had nothing to say about it. But now it is his place to give directions as to the care of the patient, and he should see to it that the food is not crowded. He should always consider the general condition of the patient when in health, and his age, digestive powers, and habits, and bear in mind that there is more danger of overcrowding the food than of not giving enough.

MEDICAL SOCIETIES.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

(Continued from page 686.)

It has already been stated in this memoir that cerebral meningeal syphilis may coexist with various forms of insanity, and cases have been cited in proof thereof. It is, of course, very probable that in some of such cases there has been that double lesion of membrane and gray brain-matter which has just been demonstrated by report of autopsies; further, if we find that there is a

syphilitic insanity, which exists without evidences of meningeal syphilis, and is capable of being cured by anti-specific treatment, such insanity must be considered as representing the disease of the gray matter of the brain. Medical literature is so gigantic that it is impossible to

exhaust it, but the following list of cases is amply sufficient to prove the point at issue, namely, that there is a syphilitic insanity, which exists without obvious meningeal disease, and is capable of being cured by anti-syphilitic treatment:

No.	REPORTER AND JOURNAL.	SYMPTOMS.	RESULTS. REMARKS.
1	Louis Streissand Die Lues als Ursache der Dementia. Inaug. Diss. Berlin, 1878.	Epilepsy, delirium of exaltation, alteration of speech, headache, failure of memory.	Rapid cure with mercury.
2	Ibid	Delusions, delirium, general mania, great muscular weakness.	Cure with mercury.
3	Dr. Müller, of Leutkirch Journal of Mental Dis., 1873-4, 561.	Symptoms resembling general paralysis, and diagnosis of such made until a sternal node was discovered.	Cure by iodide of potassium.
4	Fr. Esmarch and W. Jersen . . . Allgem. Zeitschrift f. Psychiatrie.	Sleeplessness, great excitement, restlessness, great activity, incoherence and violence.	Cure by mercury.
5	M. Leidesdorf Medizin. Jahrbücher, xx. '64, 1.	Complete mania, played with his excitement, and entirely irrational.	Complete cure by iodide of potassium.
6	Dr. Beauregard Gaz. Hebdom. de Sci. Med. de Bordeaux, 1880, p. 64.	Symptoms resembling those of general paralysis.	Cure by iodide of potassium.
7	M. Rendu Ibid.	Loss of memory, headache, irregularity of pupils, ambitious delirium, periods of excitement, others of depression, embarrassment of speech, access of furious delirium ending in stupor.	Mercurial treatment, cure.
8	ibid	Hypochondria, irregularity of pupils, headache, failure of memory, melancholy, stupor.	Mercurial treatment, cure.
9	Dr. Albrecht Erlenmyer Dei luëteschen Psychosen, Nuewied, 1877.	Melancholia with hypochondriasis, sleeplessness, fear of men, and belief they were all leagued against him.	Iodide of potassium, cure.
10	Ibid	Religious melancholia, with two attempts at suicide, ending in mania.	Iodide of potassium, cure.
11	Ibid	At times very violent, yelling, shrieking, destroying everything she could get hands on, at times erotomania; no distinct history of infection, but her habits known to be bad, and had bone ozœna and other physical syphilitic signs.	Iodide of potassium, cure.
12	Ibid	Epileptic attack followed by a long soporose condition, ending in mental confusion, he not knowing his nearest friends, etc., almost dementia.	Cured by mercurial inunction.
13	Ibid	Great fear of gendarmes, etc., mania, with hallucinations, loud crying, yelling, etc., then convulsion, followed by great difficulty of speech.	Cured by mercurial inunctions with iodide internally; subsequently return of convulsions, followed by hemiplegia and death.
14	Ibid	Great unnatural vivacity and loquacity, wanted to buy everything, bragged of enormous gains at play, etc.; some trouble of speech.	Iodide of potassium cure. Attended to business and seems as well as before. Relapsed. (See Symptoms.)

NO.	REPORTER AND JOURNAL.	SYMPTOMS.	RESULTS. REMARKS.
	Ibid Relapse of case 14.	Fifteen months after discharge from asylum, relapse; symptoms developing very rapidly, delirium of grandeur of the most aggravated type with marked progressive dementia, failure of power of speech, and finally of locomotion.	Failure of various anti-specific treatment.
15	Dr. A. Erlenmeyer Die luëteschen, etc.	Failure of mental powers, inequality of pupils, trembling of lip when speaking, uncertainty of gait, almost entire loss of memory, once temporary ptosis and strabismus.	Iodide of potassium in ascending doses failed. Recovery under mercurial inunctions.
16	Ibid	Failure of mental powers, pronounced delirium of grandeur, hallucinations of hearing, failure of memory, strabismus and ptosis coming on late.	Iodide of potassium, corrosive sublimate injections. Cure.
17	Ibid	Failure of memory and mental powers, slight ideas of grandeur, disturbance of sensibility and motility, aphasia coming on late.	Cure with use of iodide and mercurial inunctions.
18	Ibid	Melancholy, great excitability, ideas of grandeur, after a long time sudden ptosis and strabismus.	Iodide of potassium failed; mercurial course improved; joint use cured patient.
19	Ibid	Various cerebral nerve palsies, great relief by use of mercurial inunctions, then development of great excitement, delirium of grandeur, failure of memory and mental powers, and finally death from apoplexy; no autopsy.	
2	Dr. J. B. Chapin. Amer. Journ. Insanity, vol. xv. p. 249.	Melancholia with attempted suicide, epilepsy, somnolent spells.	Iodide of potassium, cure.
21	Ibid	Acute mania, noisy, very destructive; syphilitic disease of tibia.	Iodide of potassium, cure.
22	Dr. Snell	Maniacal excitement.	Cured by specific treatment.
23	Wm. Smith Brit. Med. Journ., July, 1868, p. 30.	Apathetic melancholy, indelicate, speaking only in monosyllables, and much of the time not at all, sullen and menacing.	Rapidly cured by conjoint use of iodide and mercurial. The symptoms first developed 3 months after chancre.

A study of the brief analyses of symptoms just given shows that syphilitic disease of the brain may cause any form of mania, but that the symptoms, however various they may be at first, end almost always in dementia, unless relieved.

Of all the forms of insanity, general paralysis is most closely and frequently simulated by specific brain disease. The exact relation of the diathesis to true, incurable, general paralysis, it is very difficult to determine. It seems well established that amongst persons suffering from this disorder, the proportion of syphilitics is not only much larger than normal, but also much larger than in other forms of insanity. Thus Dr. E. Mendel (*Progres. Paral. der Irren*, Berlin, 1880,) found that in one hundred and forty-six cases of general paralysis, one hundred and nine, or 75 per cent., had a distinct history of syphilis, whilst in one hundred and one cases of various

other forms of primary insanity only 18 per cent. had specific antecedents.

Various opinions might be cited as to the nature of this relation between the two disorders, but for want of space the curious reader is referred to the work just quoted, and to the thesis of C. Chauvet (*Influence de la Syph. sur les Malad. du Syst. nerveux*, Paris, 1880,) for an epitome of the most important recorded opinions.

Those who suffer from syphilis are exposed in much greater proportion than are other persons to the ill effects of intemperance, sexual excesses, poverty, mental agony, and other well-established causes of general paralysis. It may be that in this is sufficient explanation of the frequency of general paralysis in syphilitics, but I incline to the belief that syphilis has some direct effect in producing the disease. However this may be, I think we must recognize as established, the

opinion of Voisin (*Paralyse générale des Aliénés*, 1879.) that there is a syphilitic peri-encephalitis which presents symptoms closely resembling those of general paralysis. Such cases are examples of the pseudo-paralyse générale of Fournier (*La Syphilis du Cerveau*, Paris, 1879).

The question as to the diagnosis of these cases from the true incurable paresis is of course very important, and has been considered at great length by Voisin (*loc. cit.*), Fournier (*loc. cit.*), and Mickle. (*Brit. and For. Medico-Chirurg. Review*, 1877.)

The points which have been relied upon as diagnostic of syphilitic pseudo-general paralysis are:

The occurrence of headache, worse at night and present amongst the prodromes.

An early persistent insomnia, or somnolence; early epileptiform attacks.

The exaltation being less marked, less persistent, and perhaps less associated with general maniacal restlessness and excitement.

The articulation being paralytic rather than paretic.

The absence of tremulousness, especially of the upper lip (Fournier).

The effect of anti-specific remedies.

When the conditions in any case correspond with the characters just paragraphed, or when any of the distinguishing characteristics of brain syphilis, as previously given in this memoir are present, the probability is that the disorder is specific and remediable. But the absence of these marks of specific disease is not proof that the patient is not suffering from syphilis. Headache may be absent in cerebral syphilis, as also may insomnia and somnolence. Epileptiform attacks are not always present in the pseudo-paralysis,

and may be present in the genuine affection; a review of the cases previously tabulated shows that in several of them the megalomania was most pronounced: and a case with very pronounced delirium of grandeur, in which the autopsy revealed unquestionably specific brain lesions may be found in Chauvet's Thesis, p. 31.

I have myself seen symptoms of general paralysis occurring in persons with a specific history, in which, of these so-called diagnostic differences, the therapeutic test was the only one that revealed the true nature of the disorder. In these persons a primary, immediate diagnosis was simply impossible.

Case fourteen of our table is exceedingly interesting, because it seems to represent as successively occurring in one individual both pseudo- and true general paralysis. The symptoms of general paralysis in a syphilitic subject disappeared under the use of mercury, to return some months afterwards with increased violence, and with a new obstinacy that resisted with complete success anti-syphilitic treatment. Such a case is some evidence that syphilis has the power to produce true general paralysis.

In conclusion, I may state that it must be considered as at present proven that syphilis may produce a disorder whose symptoms and lesions do not differ from those of general paralysis; that true general paralysis is very frequent in the syphilitic; that the only perceptible difference is one of curability; that the curable sclerosis may change into or be followed by the incurable form of the disease. Whether under these circumstances it is philosophic to consider the so-called pseudo-general paralysis and general paralysis as essentially distinct affections, each physician can well judge for himself.

EDITORIAL DEPARTMENT.

PERISCOPE.

Thermo-Tracheotomy.

In the *Lancet*, May 10, 1884, Dr. Frank Marsh thus writes:

Few operations are easier of performance on the dead body than that of tracheotomy, and oftentimes few are so difficult upon the living, and therefore the following remarks on the use of Paquelin's thermo-cautery for that purpose may not prove uninteresting. Although of late highly recommended and frequently performed by leading Continental surgeons, notably by Poinot, Boeckel, and Krishaber, no record of this operation has appeared, to my knowledge, in recent medical literature in England. At first sight it would seem to possess great advantages over the usual method with the scalpel, the bloodlessness of the whole proceeding proving attractive, especially to the timid operator. In a certain proportion of cases, I might even say a large proportion, the use of the cautery is obviously inadmissible, time not being given for its preparation, even

were it at hand, as in spasm of the glottis from whatever cause, acute obstruction from lodgment of foreign body, acute oedema, and all those cases in which the patient is at the last gasp before the surgeon is summoned. Unfortunately, in not a few of these instances one is frequently too late even with the knife. It is also unsuitable for those cases where tracheotomy is performed for the purpose of extracting a foreign body in the air-passages, the immediate union of the wound afterwards being a desideratum if the attempt has proved successful. On the other hand, it would seem to be especially indicated in cases of diphtheria, or in syphilitic affections of the larynx, where, as a rule, the process of asphyxia is slow, and where the eschar to a great extent would prevent the infective process spreading to the wound. The disadvantages peculiar to this operation are: the hard and hot eschar on the surface of the wound, preventing the finger being used as a guide during the process of the operation; the inflammatory action in the parts around during the separation of this eschar; the increased liability to secondary hemorrhage from implication of

arteries in the sloughing process; the large wound consequently formed; and the subsequent trouble from cicatricial contraction. All these drawbacks, with the exception of the last, are well illustrated in the following case:

Ada P—, aged six, suffering from diphtheria, was admitted into the detached infectious wards on the 10th of October last (under the care of Dr. Reid), with a view to tracheotomy being performed.

On admission there was great dyspnoea, very little air entering the chest. This increased so much the next few hours that immediate tracheotomy afforded the only hope, and I decided to give the cautery a trial. The disease being extensive, it was desirable to perform the operation as low down as practicable. The child had a short and fat neck, and the thyroid veins were much engorged, owing to the partial asphyxia, material obstacles to begin with. Using a knife-shaped point, with a series of light touches (following Krishaber), keeping strictly in mid-line, and pressing forward the trachea as much as possible with the finger and thumb of the left hand on either side, the latter was at length reached a good inch from the surface, the whole proceeding being perfectly bloodless, and, so far as that was concerned, eminently satisfactory. It was almost impossible to tell the position of the trachea in the wound by tactile examination during the process, and difficult to recognize it by sight among the seared parts; the increased resistance and tendency of the cautery to roll off into the loose areolar tissue around being the chief indications it was reached. This tendency proving an obstacle to opening it, a scalpel was used for the purpose, and with some little difficulty, on account of the depth of the trachea from the surface, a bivalve cannula was introduced, over which a shield of wire, covered with two layers of gauze, was fixed, and, being occasionally moistened with oil of eucalyptus, kept the inspired air both aseptic and free from particles of dust, etc. The child immediately experienced great relief, and on the following day seemed much better, but on the third and fourth days the parts around were much swollen and inflamed, a source of much discomfort to the child. On the morning of the fifth day a severe attack of secondary hemorrhage occurred, evidently from the right inferior thyroid artery becoming implicated in the sloughing process attendant on the separation of the eschar. This was stopped by pressure of lint soaked in strong tincture of perchloride of iron, but not before a good quantity of blood had passed down into the bronchi, the cannula having been removed by the nurse at the onset of the bleeding. This caused severe dyspnoea, the child being unable to expel the blood, and in spite of remedies death took place in about two hours afterwards.

This case, I think, fairly shows the difficulties and drawbacks to this method. With the knife there would undoubtedly have been a great amount of venous bleeding, but it would soon have ceased upon the re-establishment of free respiration; also the position of the trachea could have been defined during the operation, a matter of some import when deeply seated; neither do I think that secondary hemorrhage would have occurred. Again, had the child lived there would

have been the disfigurement from a large scar, and in all probability trouble would have arisen from the pressure effects consequent on the cicatrization and subsequent contraction of an unnecessarily large wound. This, also, would have been avoided by the use of the scalpel. Now, in an adult with a fairly thin neck there is seldom any venous or capillary hemorrhage of consequence, and on this account, therefore, the cautery would hardly be needed, and it would prove but of little avail in checking bleeding from an artery of any magnitude, should one be met with, as occasionally happens, when, for instance, an additional thyroid artery is present; indeed, it would only increase the difficulty of applying torsion or ligature by the consolidation of the parts around. In adults it might be of some use in keeping the wound free from septic or other infection, the subsequent sloughing process, on account of the greater space, not to be so much feared as in the case of a child. Taking, however, into consideration all the above facts, the balance of evidence appears to me by far in favor of the older method with the scalpel, especially for children; and without detracting from the merit of a most valuable instrument, I would very strongly urge its unsuitability for the performance of tracheotomy.

Beneficial Effects of Convallaria.

After detailing a case in the *Practitioner*, April, 1884, Dr. Frederick T. Roberts says:

My experience of the use of convallaria in cases of cardiac disease has not hitherto been so satisfactory as the reports of the value of the drug had led me to expect (*Practitioner*, xxix., 226, 384); but in the case just described, the good effects resulting from its administration were marked and unmistakable. Practically, it might be summed up as a case of mitral obstructive disease, with irregular and inefficient cardiac action; deficient secretion of urine; moderate dropsy of the legs; and considerable ascites. Whether or not the last-mentioned symptom depended partly on morbid changes in the liver, is doubtful. The obvious results of the administration of the convallaria were:

1. A distinct improvement in the action of the heart, which became more regular and efficient, while the thrill and murmur became more evident.

2. A considerable and progressive increase in the quantity of urine produced.

3. Rapid diminution and ultimate disappearance of the oedema of the legs and the ascites.

The compound jalap powder helped, no doubt, to get rid of the last symptom; but the other effects noted were unquestionably due to the convallaria, and the increase in the quantity of urine must have been an important factor in removing the dropsical accumulation. I have thought it worth while to report this case in support of the value of convallaria in the treatment of cardiac affections, although I do not for a moment believe that it will entirely supersede other drugs. The patient is now practically well, so far as symptoms are concerned, but the signs of the mitral obstructive disease are very distinct.

A Case of Compound Fracture of the Leg, Treated on a New Splint.

In the *Brit. Med. Jour.*, May 10, 1884, Dr. F. T. Paul thus writes:

The following case is reported in illustration of the use of a splint which I am now recommending for the treatment of compound fractures of the leg, and disease of the ankle-joint:

Hugh R., aged 15, a rivetter, was struck by a large iron plate on the outer side of his leg. When seen, the sharp end of the upper fragment of the tibia was protruding two inches out of a wound at the inner side of the leg, in the lower third. Ether was administered, and the wound enlarged, and thoroughly carbolized. The bones were accurately fitted together, and a stout wire passed round them, and tightly twisted. Then, the patient being still under the anæsthetic, the splint was applied in the following manner:

With a strip of lead the contour of the front and back of the sound limb is taken from a few inches above the knee, down the tibia, over the toes, heel, calf, and back to the thigh. A strip of stout hoop-iron ($\frac{3}{8}$ inch by $\frac{1}{2}$ inch) covered with rubber tubing, is then bent to lie easily over the outside of the lead pattern, following all its deviations accurately, so that it may fit without pressing unduly on any part (Fig. 2). When the splint

FIG. 1.—From a photograph on the fifth day. (A) The splint. (B) The paraffin bandage. (C) The wax and carbolic oil finish. (D) The antiseptic gauze showing from under the stiff bandage. (E) The fractured limb.

FIG. 2.—The splint of hoop-iron covered with rubber tubing.

is ready (it is of course prepared before the anæsthetic is given), and the bones have been wired, the whole limb is thoroughly carbolized, and the foot and leg well bandaged with antiseptic gauze, leaving a wide interruption at the site of the fracture. Over the gauze a layer of domette bandage, saturated with hot paraffin-wax, is placed, or a plaster of Paris bandage. As soon as the stiff bandage has set, the splint is put on, and more wax or plaster bandages are applied to retain it

firmly in position. Lastly, cotton-wool is packed under the edges of the bandage at the interruption, and brushed over till saturated with Howe's mixture of beeswax and carbolic oil, and the antiseptic dressing is completed (Fig. 1). A very little subsequent care in the dressings will prevent any discharge from getting between the leg and the splint.

The advantages of this mode of treatment are that no deformity of the limb can possibly take place, as the bones are wired and permanently fixed under an anæsthetic; and that the repair is rapid, owing to the absence of movement necessary in the ordinary method of dressing compound fractures. The choice between paraffin and plaster of Paris bandages must depend upon the weight of the limb, and the fixation of the fragment. When the limb is small and the fragments are well fixed, paraffin is quite sufficiently rigid; but under the reverse conditions plaster of Paris should be used, at any rate for some part of the bandage. Paraffin is much the better material in every way, except for its want of sufficient rigidity in the warmth of the bed. In this particular case paraffin was used, and answered admirably. There was a good deal of oozing of blood through the night, but not a drop passed inside the splint. The case was dressed once a day for a week, and then every other day for a fortnight under the spray, when it was stopped, as the wound was healing well. On the eighteenth day the wire was untwisted, and the bones were quite firm. Granulations rapidly appeared in the bare bone at the bottom of the wound, and no necrosis occurred. The highest temperature attained was 100° , and that only on one occasion. On the seventh day the patient was dressed and taken to the Medical Institution in a cab, without the least pain or inconvenience, owing to the perfect support given by the splint; and now, six weeks after a severe compound fracture, he is up on the couch, with the wound almost closed, and the measurements of the leg in every respect normal.

In cases of disease of the ankle-joint with discharging wounds, the splint should be fixed with paraffin, or simply with strapping, leaving all the heel and instep open, and the leg well protected under the splint by a soft or paraffin bandage. If the heel suffer from pressure on the lower bar, the leg and foot should be attached first to the upper bar alone, and then by a bandage round both. The dressings should always be slipped between the heel and the lower bar, or discharge will collect there and decompose.

The splint may be obtained from Messrs. Krohne and Sesemann, in London, and from Mr. Critchley in Liverpool. For hospital use, for compound fracture, it is best ordered in lengths of 5 to 6 feet for adults, to be bent to pattern by the surgeon; but in private practice, and for disease of the ankle, the pattern can be traced on paper from the strip of lead, and the splint ordered about half an inch larger in all dimensions than the limb.

Abscess of the Lung.

Since we are liable at any moment to meet such a case, the following case, which Dr. McKenzie Booth reports in the *Brit. Med. Jour.*, March 8,

1884, will be read with interest as enabling us to detect the trouble: The patient was a girl aged 13, of a markedly phthisical family, who had from time to time suffered from bronchitis. About a fortnight before she was first seen, she had an attack of bronchitis; and, when seen, she was much reduced in strength, and was rapidly losing flesh. Her appetite was entirely lost. She had irregular exacerbations of fever, and severe colliquative sweats, mostly toward nightfall. Temperature 102°; pulse 120 to 140; breathing was very short and hurried; the cough and expectoration were much less than they had been. On percussion, there was slight dullness over the supraspinous fossa behind the right apex; otherwise normal. Auscultation discovered crepitant *râles* over the right apex posteriorly and anteriorly. Almost all food was rejected soon after swallowing; the bowels were much constipated. A purgative was given; sinapisms were applied over the right apex; small doses of opium and digitalis were given every three or four hours. Milk and lime-water, beef-tea, and port-wine, were administered every two or three hours. For the next few days, except that there was less vomiting, the symptoms grew more pronounced. At the end of a week, the temperature was between 103° and 104°, and the pulse could not be counted. About three weeks from the commencement of the bronchitis (eight days after she was first seen), a severe fit of coughing set in, during which pus was expectorated to such an amount as almost to choke the patient. Expectoration continued to be copious for a few days, though gradually diminishing. Percussion-dullness gave way, and for a time the resonance was almost amphoric; whilst gurgling alternated with cavernous breathing. At the end of a fortnight, the cough and expectoration were nearly gone, and the patient was rapidly gaining strength and flesh, although there was still percussion-dullness and broncho-vesicular breathing over the right apex. There was also marked swelling (due seemingly to lymphatic infiltration) over the right side of the neck above the pulmonary apex. After the discharge of the pus, the treatment consisted of carbonate of ammonia, with squills and senega, with free supplies of port-wine and nourishment, and afterwards tonics generally, and preparations of iron; and, under this treatment, the patient recovered speedily.

REVIEWS AND BOOK NOTICES.

BOOK NOTICES.

A Treatise on Ophthalmology for the General Practitioner. Illustrated. By Adol. Alt, M. D. 1 vol., 8vo., pp. 244. J. H. Chambers & Co., St. Louis.

Though ophthalmology is one of the closest specialties in surgery, it is requisite that the general practitioner should acquire a thorough knowledge of it, so far as it is concerned with the more usual diseases and minor operations. This much

Dr. Alt proposes to give in the volume before us. He treats of diseases of the eyelids, lachrymal apparatus, orbit, conjunctiva, cornea, iris, etc., giving to each a short chapter containing what he thinks most important for his purpose. Necessarily his discussion of many lesions is inadequate to rendering the reader competent to treat them. It could not be otherwise. But this is a universal fault of such compendiums.

There are a reasonable number of illustrations of moderate value which set off the text.

We must express our surprise at the author's statement in his preface that he does not know of any book on ophthalmology, written solely for the general practitioner and his wants. He must have been but little familiar with the literature of his specialty not to have known of several, as, not to speak of others, the excellent manual of Dr. Schell, of this city.

Sexual Neurasthenia: Its Hygiene, Causes, Symptoms, and Treatment, with a chapter on Diet for the Nervous. By George M. Beard, A. M., M. D. Edited by A. D. Rockwell, A. M., M. D. 1 vol., crown 8vo., pp. 270. Price, \$2 00. E. B. Treat, publisher, 757 Broadway, New York.

This work was one of the latest, if not the latest, production of the lamented Dr. Beard. It is strikingly characterized by both the faults and the merits of his style and method. He rarely wrote a dull page, and rarely advocated a sound theory. Adopting early the biological views of the English positivists, he carried them without misgiving to their utmost limit in the discussion of medical questions. It is really curious to see how he accepted without question any result which he thought to follow from his theory of evolution, and strove to make facts support it. In this work, for instance, he defends anthropophagy as the most suitable diet for man.

This volume deals with those cases of nervous exhaustion, which he claimed were due to sexual excess in the male. His descriptions are vivid and his suggestions often valuable; but many of his cases would receive another name from those less exclusively given to theories of nervous diseases.

—Those who would like to see a more than usually learned exposition of the principles of the eclectic school of medicine should read a short pamphlet, entitled "The Scientific Basis of Eclecticism in Medicine," by Dr. C. A. F. Lindorme, of Topeka, Kansas. His statement of the principles is based upon the dynamic relation of drugs to diseases.

THE
Medical and Surgical Reporter,
 A WEEKLY JOURNAL,
 ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
 JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

 PHILADELPHIA, PA.

AN OBSTETRIC CASE

(Price, \$15.00),

OR

AN ELECTRIC BATTERY

(Price, \$25.00),

AS PREMIUMS.

Any subscriber to the REPORTER who will send us before the 1st of July the names of *three* new subscribers with their yearly subscriptions (\$15) or *five* new subscribers with \$25.00, will receive, for the three, an Obstetric Case complete, and for the five, an Electric Medical Battery complete. They are new, of the best make, and of guaranteed excellence. The new subscribers will receive the REPORTER free from the date of the remittance until July 1st next.

Address DR. D. G. BRINTON,
 115 South Seventh Street,
 PHILADELPHIA, PA.

CARELESSNESS OR IGNORANCE?

The French as well as the German Government have each sent a separate scientific commission to Egypt for the purpose of investigating the cholera epidemic there. The French Commission returned home in January, all through with its work, and reported, "that they had detected the real cause of the Asiatic cholera, and that this was to be found in a bacillus," of which they gave description and drawings. The German Commission continued its diligent researches for several weeks longer, and then went to Calcutta, there to make further investigations. Dr. Koch (discoverer of the tubercle bacillus), the President of the German Commission, sent his fifth report home from Calcutta in January. From this report we translate its last part, as the report of the French Commission regarding its discovery of the pathogenic cause of cholera has given rise to a great deal of dispute. Dr. Koch writes:

"From medical journals I have learned that the French Commission sent to investigate the cholera epidemic in Egypt has said in its report that it had arrived at conclusions differing from those I respectfully submitted, and that it had discovered in the blood, organisms which it considers to be peculiar of cholera. This makes it appear as if the German Commission had taken the wrong path, and I consider it, therefore, my duty to give your Excellency my views of the French report.

"There are found in varying numbers in the blood of the healthy human being, aside from red and white globules, small, round, pale form-elements, the so-called blood-discs (blutplättchen). In some febrile diseases, as typhus, pneumonia, these discs are greatly augmented in number, and on account of their resemblance they have been frequently taken for bacteria. In the blood of persons suffering from cholera, and in that of cholera corpses they are also mostly augmented, as we have constantly observed in our investigations. Besides, this fact is by no means new, but has been already mentioned by former investigators. So, for instance, D. D. Cunningham in his article, 'Microscopical and Physiological Re-

searches into the Nature of the Agent Producing Cholera,' has already given (1872) a very good drawing of these form-elements in the blood of cholera patients. And as the most approved methods have not enabled us to recognize in this blood any other elements, which had any resemblance to bacteria; and as further the description given by the French Commission exactly corresponds to that of the blood-discs mentioned, I am forced to the conclusion that the French Commission has committed the same error as other investigators before it, and has taken the blood-discs for specific organisms. Any etiological connection between cholera and these blood-discs cannot possibly exist, for these discs, as already mentioned, are met with in the blood of healthy, and also of such persons as suffer from other diseases."

It is less the mistake, for *errare est humanum*, but the fact that the French Commission made so much noise of its discovery, and hinted at its superiority over the German Commission. The French Government will now be sorry that it has not at least sent men who were acquainted with all that is known of the normal and abnormal constituents of the blood, as it is plain that only such men are competent to institute researches of so difficult a kind.

We may add, that Koch succeeded in Calcutta, two months ago, in discovering the real bacillus of cholera; it is met with only in the intestines, and is greatly distinguished from all other microzymes.

HOPE AS A REMEDY AGAINST DISEASE.

Dr. J. Mortimer Granville has been lately rather severely handled by the Medical Press of London, because he wrote a letter on this subject to one of the daily papers. He is criticised as having performed an unethical act in thus advertising himself in an unprofessional manner in a lay journal. This question we will leave to our transatlantic brethren, while we say a few words upon the subject-matter of his letter.

But little touched upon, Hope, as a remedy against disease, is, if wisely and judiciously em-

ployed, one of the most valuable and useful means that the physician can employ. Call it what we may, and reason about it as we please, no man of experience will for an instant question that imagination, the prejudices, the mental condition, the conviction of the patient, in many cases, exerts a most powerful and a most real influence upon the progress and termination of diseased conditions. Has it not happened to every one of our readers (it repeatedly has to us) to discover accidentally, so to speak, a condition of chronic disease, which has evidently been present for years, and yet the patient has maintained fairly good health, and is, at the time of the discovery, in no immediate apparent danger; yet when told that he is afflicted with an incurable disease that may carry him off in a few days, or that he may live for months, immediately wilts, like the sensitive plants when touched, and dies in a day or two?

Again, do we not all know of cases of chronic disease, in persons with a happy, hopeful, contented disposition, disease that we felt sure would soon prove fatal? and yet we see them go on day after day and year after year enjoying apparently good health. Of course we are familiar with and thoroughly recognize the fact that worry, that mental anxiety, is diametrically opposed to good health and long life; and in this fact we recognize the explanation of the influence of depressing opinions and advice; for if we tell a man with a nervous temperament that he *may* die in a few days, from that moment all peace and contentment vanishes from his life, while anxiety, worry, and unrest takes possession of his whole being.

The practical point to be deduced from these reflections is that it will redound not only to your patient's advantage, but also to your own professional reputation, to make it a rule always to take the most hopeful view that is possible of the patient's condition, especially when the man or woman is one of the "nervous, worrying kind," and always to remember that "hope kept alive" is the great secret of success among quacks. Let us steal their thunder.

THE RESPONSIBILITY OF OBSTETRICIANS.

In some papers sent us lately from New Zealand, there is the report of a case of a Dr. Parry, who attended a woman in confinement. Her death ensued suddenly, and was found on post mortem to have been brought about by rupture of the vagina. It was alleged that the rupture was caused by the rough measures of the medical attendant, but there was no conclusive evidence of this submitted.

The physician was indicted for manslaughter, and although the testimony was conflicting and insufficient to a medical mind, he was convicted and sentenced to four months' imprisonment.

The New Zealand Medical Society held a meeting to discuss the subject, when a resolution was passed that the verdict in the case was not warranted by the evidence.

Dr. Parry had not used any instruments, and the society expressed its opinion by a unanimous vote that the highest obstetrical authors unite in saying that ruptures of this nature nearly always depend on diseased conditions of the vaginal tissues. Some have occurred in the most skillful hands; and when they take place without the violent use of instruments, they may be considered proofs of pathological changes in the walls of the organ.

We note this case, as it is one of general and grave importance. It might happen to any one at any time, and that a physician should lose his liberty and reputation from the ignorance of a jury is something that we should be on our guard against. The matter is one which merits a special study by medico-legal writers and obstetricians. We shall be glad to receive and publish any original observations calculated to elucidate this point.

NOTES AND COMMENTS.

The Pyrexia and Cold Bath Treatment of Enteric Fever.

This is the topic of the hour in England, and many papers on the subject are found in our exchanges. In the *Brit. Med. Jour.* for April 12, 1884, we note a paper by Dr. Francis H. Welch, in which he maintains that the pyrexia is less an

exponent of the extent and degree of the gland lesion than of the impressionability and sympathy of the system to the progressing changes; and, upon the whole, it seems that the younger the individual, the more pronounced will be the pyrexia and general symptoms, and the less the possibility of gauging the gland lesion by the temperature records. With reference to the cold bath treatment, he says, "Cooling applications are always grateful to the patients, and beneficial; but immersion in a bath is a process (even when we have all the requisite appliances at hand) which requires a skilled and trained official and attendants to regulate its effects and ward off possible bad results. And, carry it out as carefully as we may, a certain amount of discomfort, physical and mental disturbance cannot be avoided. It is difficult to prevent the patient from exerting himself, and the younger the patient the more the probable disturbance. What has seemed to me the best course to pursue in the application of cold to the skin generally is, in mild and moderate cases, to frequently sponge the body with water feeling "chilly," say every half hour, not wiping it off, and merely covering the surface with a light sheet, or not even that; in the severe cases, to make the applications continuous by a small sheet wrung out in cold water (and made more so, if necessary, by experience) and packed close to the naked body, with a light outer covering, and repeated according to results.

Such a packing is within the scope of an ordinary attendant, can be carried out without inconvenience or movement to the patient, the materials can always be got, and a waterproof covering under the lower sheet will keep the bed dry. Moreover, I believe that it will meet all the requirements of the great majority of cases. Instances, however, will occur in which the body-temperature cannot be reduced by it, and resort may then be had to the bath to meet the pressing danger. Yet even the influence of the bath is limited: and I suppose most have met examples in which repeated immersions have failed to stop the production, or prevent the accumulation, of excessive heat in the frame, the patient succumbing to its effects in spite of all our efforts.

It is hardly necessary to add that movements of air over the body will assist the influence of the cool applications, nor would it be difficult in most rooms to rig up a "punkah" to carry this out more effectually.

A Rapid Case of Acute Cerebro-spinal Meningitis.

The following case, which Dr. Albert Wilson

reports to the *Brit. Med. Jour.*, April 12, 1884, is interesting on account of the extreme rapidity with which it passed through the three stages of cerebral fever (Trousseau) or cerebro-spinal meningitis. Each stage lasted twenty-four hours:

"I was sent for at the commencement of the second stage. The patient, Mr. A., aged nearly eighteen, was in good health on the 21st of February, 1884. On February 22, he complained of headache at the forehead and posteriorly, loss of appetite, pain in the stomach, and constipation. At night, he vomited green fluid, and was restless. This was the first stage. On February 23, at 5 a. m., the parents were awoke by moaning, and found him tossing about in bed, and unable to speak. I saw him at 6 a. m. The patient was semi-conscious, very pale, throwing his arms and legs about, and rubbing his stomach; his eyes were half open, and very watchful of all my movements. The conjunctivæ were sensitive; the pupils dilated. He always pushed my hand away when I touched him, and if offered food, would knock the spoon or cup away. The skin was cool. Pulse 72; the tracing was normal. He was too restless for the thermometer to be used. I ordered twenty grains of bromide of ammonium and ten grains of chloral every two hours till he was quieter. There was nothing to account for the illness except over-study. At 11 a. m., his condition was the same. There was no rigidity of muscles nor epileptic state. Food and medicine had to be forced, the patient resisting his utmost, even trying not to swallow. He moaned constantly, and was worse when his relations approached, and strongly disliked my presence. His watchfulness was very marked, but he could not speak. The last time he spoke was about 1 a. m. At 4 p. m., he passed motions and urine in the bed. He fell out of bed twice. In both cases, he was found in a sitting posture, the head and shoulders resting against the bed. He did not at any time hurt himself or strike against anything hard. At 10 p. m., he had had four doses of bromide of ammonium and chloral, and also two thirty-grain doses of bromide of ammonium, but without any soothing effect. Pulse 72; skin cool. The restlessness and moaning had increased. The patient did not sleep during the night. This ended the second or 'apyretic' (Trousseau) stage. The respiration was not irregular, which is unusual.

"On February 24th, 11 a. m., the third stage commenced. Muscular excitement was diminishing. The thumb was tightly opposed, and the flexed over it. The head and neck were forcibly retracted. The limbs were flexed. The stomach

was retracted. There was no purposive resistance, although he had great difficulty in swallowing, and was very restless. Pulse 100; skin hot and dry. The conjunctivæ were injected; the pupils contracted. He was comatose, moaning constantly. Large quantities of urine were passed involuntarily. At 4 p. m. he was seen in consultation with Dr. Hughlings Jackson. There was much less muscular resistance, and he swallowed quietly. Opisthotonos was increased. Pulse 120. Temperature (axilla) 103.6°. The optic discs were normal. The tendon-reflex was normal. The bromide was continued in thirty-grain doses, with the addition of ten grains of iodide of ammonium. At 10 p. m., coma was deeper. The head was more retracted. He was almost unable to swallow, but since 4 p. m. had had two doses of his medicine. Temperature 104°; pulse 120. He died at 8 a. m. on February 25th.

Dislocation of the Wrist.

Since dislocation of the wrist-joint without fracture of the radius is a very rare accident, the occurrence of which is denied by some surgeons, the following case which Dr. John Cochrane reports in the *Edinburgh Med. Jour.*, May, 1883, possesses peculiar interest. Two boys were running at great speed and a collision was unavoidable, and in order to break the shock his patient had held up his hand and received the impetus on the palmar surface with such violence as to immediately throw the wrist out of joint. The physical signs of dislocation were quite evident, and there was thorough distortion. He placed a splint along the palmar surface and bandaged the hand and arm, and ordered perfect rest. In the evening he saw him again, and he still felt very easy. In the course of the next day, however, considerable swelling of the tendinous sheaths of the muscles of the arm appeared, and there was now considerable pain in that direction. This was evidently due to the amount of stretching, etc., which the muscular structures had undergone.

Under the effects of turpentine stupes, and laudanum locally applied, swelling and pain rapidly subsided, and the patient made a rapid progress towards recovery. The temperature never went very high during this attack of inflammation. For a few days afterwards he wore the arm in a sling. At the date of report he had perfect use of the joint and suffers from no bad effects.

Pneumonia Treated by Cold Baths.

M. Gignoux, of Lyons, has lately published a paper consisting of details of five cases of pneu-

monia. In four of these cases he had resorted to baths, and in one to cold applied by means of compresses of ice-cold water renewed at intervals of five minutes, a bath not being at hand. All were severe cases; four recovered, and one died. The fatal case appeared to derive benefit from the bath, although the pulse was sufficiently feeble from the first to warrant a foreboding of death. The treatment was carried out with much resolution; one patient had thirty-two baths in seven days; another fourteen in three; and in the case which proved fatal they were given regularly every three hours for three or four days. The temperature of the baths ranged from 68° to 75° F. M. Gignoux, from his experience, thinks very highly of the baths; and these cases, although few in number, are carefully reported, and will make a valuable addition to the now accumulating experience of this plan of treatment in pneumonia. The pamphlet is entitled *Observations de Pneumonies traitées par les Bains Froids*.

The Specificity of Gonorrhœa.

In the course of his remarks on gonorrhœa, before the Philadelphia County Medical Society, which we have noticed elsewhere, Dr. White related the following: A patient of his had a mistress, with whom he had lived for many years—in fact, they were practically man and wife. Dr. W. was sure that the woman was true to the man. The man contracted a urethritis, as Dr. White believes, from some innocent muco-purulent discharge from his mistress. He went to his family physician, who told him that he had gonorrhœa; but not believing in its non-specificity or through negligence, failed to impress upon him the fact, which Dr. White seems firmly to believe, that urethritis or gonorrhœa is not necessarily derived from a pre-existing specific disease. The man, therefore, suspecting his 'mistress, abandoned her with harsh words. She, deprived, unjustly as she believed, of the support and love to which she had been accustomed for so many years, became despondent, and within ten days committed suicide.

Resection of the Ribs in Empyema.

As of interest in connection with the paper by Drs. Bruen and White, recently published in our pages, we note that at a recent meeting of the Paris Société de Chirurgie (April 23), M. Hermann, of Mulhouse, read notes of a case of multiple rib resection for an empyema which had existed many years. By means of an I-shaped incision, of which the central line corresponded to

the axilla, he resected long pieces of the third, fourth, fifth, sixth, seventh, and eighth ribs, under strict antiseptic precautions. The result was not satisfactory, repair not taking place, so that ten weeks after the operation there was a large excavation exposing the diaphragm and lung covered by granulations. From this experience, Hermann agrees with Berger that it is well not to operate when the lung is firmly adherent posteriorly. Probably he would have obtained a better result had he contented himself with a less radical measure, or performed the resections at intervals instead of at one operation.

Wood-wool Dressings.

We had occasion some time since to refer to this article as a dressing for wounds, and we now note from the *Lancet*, April 12, 1884, that Mr. Ormsby, of the Meath Hospital, Dublin, has recently been using wood-wool dressing after operations, and speaks highly of it. The following are brief notes of a case in which this method was used: A man aged fifty-three was admitted for disease of the tarsal bones of the left foot, extending for some distance into the lower ends of the tibia and fibula. Amputation was performed a hand's breadth below the knee-joint, ether being administered by the Ormsby inhaler; Carden's method, by oval skin flaps and circular division of the muscles, being the operation adopted. At the second dressing wood-wool was applied. There was a little secondary hemorrhage, which was easily controlled, and the case has progressed favorably.

Fracture of the Patella.

To the New York Surgical Society, at a recent meeting, Dr. F. Lange presented a patient, a man sixty-two years of age, who illustrated the usefulness of a limb after fracture of the patella, in spite of a distance of three inches between the fragments. The patient had had fracture of the patella several times, and the last time the injury occurred three or four years ago, and there was also rupture of the crucial ligaments, as evidenced by hyperextension of the knee-joint and great lateral mobility. The plan of treatment which Dr. Lange adopted was similar to that recommended by Dr. Little, and the immediate result was very good; but after a time the gap between the fragments began to increase and afterward became quite extensive, and measured three inches; and yet the patient was able to walk quite well, could go up and down stairs, and could exercise the limb very well.

CORRESPONDENCE.

Hobby Riders.

EDS. MED. AND SURG. REPORTER:—

Your very excellent journal has contained nothing so refreshing in a long time as was the article by Dr. Mitchell in the issue of May 3. I wish that every young man in the profession could read that article. It is not alone brim-full of solid facts, but they are couched in terms so plain and have such a convincing way with them that the article cannot fail to do good. It, indeed, was high time that some one should stand out and cry "halt" to the rushing mob who are willing to follow the leader who has the loudest voice. I am glad to see that the attempted revival of an antiquated and barbarous treatment for pneumonia has received a good and sudden set-back at the hands of a medical man who can show experience as well as philosophy for his position.

At the time of their appearance, I read Dr. Corson's articles. The venerable doctor's plea for general depletion seemed to me to be not only a lame one, but also one that modern pathology could not explain. But here is a man who has practiced many, many years. He has cured many cases of pneumonia. He bled regularly. If I were to object to this treatment and give all of the very many indisputable reasons why such treatment is both unnecessary and unreasonable, he would silence me by one question: "How long have you practiced medicine?" Are the long years of constant study and observation to be overthrown by the theories of striplings? Well, that depends.

At a glance, the errors these older members of the profession sometimes make do not seem to stand out in the bold relief they really do, owing to the fact that a large class of the profession are ever on the alert for footsteps to follow. It is all very well for our professional teachers to admonish students to "hew to the line," and all that. It is an undeniable fact that a great majority of them are followers—not leaders. They are content to accept the "say-so" of others, and have no itching desire to be other than routine practitioners. This is the class to whom just such articles as Dr. Corson's do inestimable harm. That the lancet is often of value in the treatment of disease, no one doubts. But the attaching of undue importance to its use in any particular disease is where the error creeps in. I am acquainted with two very estimable physicians, one of whom gives quinine for everything almost, while the other very seldom gives it. These preferences and prejudices are in a mild way hard to guard against; but when let run riot, they work great evil for those who are not able to shield themselves from constant bias. This hobby-riding is carried to a lamentable extreme in many of our medical schools. I well remember how two professors in one of your city's colleges spent much valuable time one winter, in '76, over "bleeding in puerperal convulsions." The discussion did not amount to anything. The favorites of each believed all that one said, and nothing that the other said. In the heat of the discussion, many of the students failed to see that both men were

right, and both wrong. To take blood from every patient having puerperal convulsions would be as poor practice as to bleed every case of pneumonia. Some of both should be bled; and to tell which to bleed and which not to bleed, requires the knowledge and judgment which alone distinguish the progressive, active, live physician from the hum-drum doctor.

If all medical men did their own thinking, such articles as Dr. Corson's could not fail to do good, since the mere mention of such extreme views by a man of years and experience would set men to thinking on the subject. Since there is no top round to the ladder, many, too many, members of our profession are content to climb only so far as is necessary, and there stop. These are the men to whom these hobbies do great damage. Struck by the beauty of diction, they lose sight of the main question, and follow the writer or speaker, never once questioning his utterances or weighing his deductions. These are the men who fill the medical journals of the land with miraculous cures. Their stereotyped form runs like this: "Was called to see W. M., 8 years old; had fever, dry cough, etc., etc. Diagnosed membranous croup. Gave syrup of squills 20 drops and sulphate of copper 2 grains every hour. Case recovered in two days." Intelligent men who know anything about the disease, know that such cures are stuff. And yet twenty years hence that same reporter will regale us with just such thin facts.

Homœopathy doubtless had its origin in the abuse of good medicines by old-school physicians. It is not so very long ago that to be attended by an old-school doctor meant bleeding, salivation, and hypercatharsis, no matter what the disease was. Is it any wonder that a new line of practice sprung out of such horrible torture? A leech and suffering people were willing to embrace anything that promised immunity from treatment little less severe than the disease. Any relief, even one teeming with the sophistry of a Hahnemann, might be embraced.

Magazine writers and the professors in our too-numerous medical schools should exercise the wisdom and judgment in their utterances that many of them fail to do. A distinguished member of the profession in Iowa, and the head of one of our schools, said to his class: "When in doubt, give the iodide of potassium." Can a sane man imagine a more senseless bit of advice? When in doubt, get thee to a library! Young men who quit the plow and workshop, with little preparatory learning, to enter the great band of unwarded doctors, swallow such utterances *in toto*.

The remedy for all this must come from within—careful study to learn what is true—and by keeping a sharp lookout for what is false. A determination not to be hobby-riders will make many of our writers and teachers much more useful and much less dangerous members of the profession, while the stigma that attaches to cranks will not so frequently be justly attached to us as a hard-worked, poorly-paid council. J. A. DE ARMOND, M. D.

Le Claire, Iowa.

Again—Conception without Intromission.

EDS. MED. AND SURG. REPORTER:

The REPORTER having in the issue of March 11,

1884, noticed the discussion by Risoni concerning the manner and method of conception, two physicians have since reported in its columns cases clear and sure, of conception without intromission, to which list I now make my addition.

An unmarried lady of 21 years of age applied to me for relief of amenorrhœa. Her full habit, glowing cheeks, red lips, and general picture-of-health appearance, told heavily against anemia. Close questioning revealed that she had a beau. Being a strict Catholic, she had always forbidden him sexual indulgence, but she had allowed him to skirmish the marriage state by placing his penis against the vulva, and thus lying together without intromission. While in this position, an emission had occurred.

This was a puzzle. Was she pregnant? Time will tell, I thought; so writing a placebo prescription, she was dismissed.

A few months later she came boisterously into my office, sobbing and lamenting, "Oh! I know it is so—I know it is so; I feel it more," she cried. A digital examination, aided by a thorough ocular inspection, showed an unruptured hymen, with a circular opening the size of a dime. Auscultation gave clearly the fetal heart-beat, and in due time a bouncing boy was announced to the world. This would seem to illustrate again the possibility of impregnation without the semen being injected within the uterus.

One criticism I would suggest of Dr. Cass' report of April 12, in the *REPORTER*. He censures Americans as being led too easily by European teachers, and hints that we follow them in their theories of conception. In Reese's edition of Taylor's Medical Jurisprudence, occurs the following paragraph, page 718: "It has been a question, whether when intercourse has taken place against the will of a woman, pregnancy could possibly follow. It was at one time thought that the will of a woman was always necessary to the act of impregnation, and therefore if she became pregnant she must have consented to the act, and that the charge of rape was unfounded. Such a defence would not be admitted. Conception, it is well known, does not depend on the consciousness or volition of a female. EVEN PENETRATION TO THE VAGINA IS NOT ABSOLUTELY NECESSARY FOR IMPREGNATION." C. C. VANDERBECK, M. D.

Philadelphia.

NEWS AND MISCELLANY.

Iowa State Medical Society.

Reported by J. F. KENNEDY, M. D., of Des Moines.

The thirty-second annual session was held in Des Moines May 21–24, with President S. E. Robinson, M. D., in the chair. The attendance was unusually large, owing to the fact that Iowa had sent to the American Medical Society at its late session the largest delegation present except that from Pennsylvania. There were 122 registered as permanent members and 66 as delegates, making the total number present, including visitors who became members by invitation, fully 250.

The session was one of the busiest ever held by the society.

At 2:30 p. m., 21st, President Robinson delivered his annual address, in which he said:

"I desire for a few moments to call your attention to the present condition, socially and ethically, of the medical profession in the State; as observed from my standpoint as a country practitioner. And while I believe this to be quite a pleasing condition in both these particulars, I may suggest something in the way of further improvement. It is, perhaps, more difficult for one to judge of present conditions and tendencies of a class, of which he is an integral part, and of its needs, than of any other question which he could consider. One could easily judge of the condition of a class or a profession in the past, if he were furnished with the history of its surroundings; but our judgment is liable to be warped by personal interests when we come to investigate present conditions of a class to which we belong. There seems to me to be good reason for satisfaction with the social standing of our fraternity. We here in Iowa have no especial ranks or grades in society to strive for or boast of, but we have in every community varying degrees of education and intellectual attainment; and the honest, intelligent physician everywhere, in city and country, finds himself associated with the best intelligence, and a co-worker and peer of the best educated in every community, a welcome visitor in health as well as in sickness, in every grade of society in the community in which he lives. But we find that nearly every locality is able to judge between the intelligent, educated physician and the ignorant, uneducated pretender who may, in some unaccountable way, have attained the title of "Doctor." The first is usually a leader in society, looked up to as an adviser and counsellor in educational, literary, and social affairs, while the latter has no place except as a hanger-on, being tolerated, but not desired, in any neighborhood in the State. And yet, by reason of legislation in some of our neighboring States, tending to protect their citizens from this kind of impostors, we have more than our just proportion of this class of parasites subsisting upon the uninformed and unfortunate. And I believe it to be the duty of this society, and of the individual members of the profession, to renew and redouble the effort recently made to secure such legislation as shall be a partial protection, at least, to the people of the State from the plundering by the soulless villains who are ready to prey upon the credulity of the poor and suffering, and to relieve our State from the odium that attaches to it as the cess-pool for the degenerate material thrown off by the profession of neighboring States, by the help of good legislation.

"There is probably no man in any community who has or could have greater political influence than the practicing physician; he comes in contact with every class in the community, the educated and the ignorant, the rich and the poor, and with all he stands in great respect, every one esteeming his judgment and highly respecting his opinions. Yet there is, perhaps, no class of equal number, who really exercise so little political influence, in matters of which it is recognized to be most thoroughly informed, and upon which it is so nearly agreed. There must be some reason for this, and for the common outside prejudice that

exists which becomes apparent so soon as we as physicians urge the consideration by our legislature of any matter having any relation to our profession. Just so soon as we were agreed upon a law which we could recommend to the legislature and to the people, as furnishing them some protection and tending to secure for them better medical service (this we accomplished without difficulty when we first considered the matter), then we heard from every school district in the State a cry 'that the doctors are trying to secure protection; they want a law enacted that will give them better business and increase their income.' Now, why was this so, and why did the people and the law-makers misjudge our motives? They will give us credit for honesty and integrity in other matters, why not in this? I think it may be due in some measure, at least, to our professional sensitiveness. We all know that professional benefits were not thought of by the committee that gave especial consideration to the question of medical legislation, and we all with one accord said so—and the law has not yet been enacted. The majority of the profession ceased to actively use their influence in that direction, lest their motives continue to be misjudged, and the few who continued to urge it could only fail of success. Suppose it were true that we were in need of protective law, or would be benefited by the measures proposed and desired, is there any disgrace attached to that? Do not men engaged in every other legitimate business desire and work for such measures as shall enable them to pleasantly and profitably pursue their several avocations; the farmer and the mechanic, the merchant and the manufacturer, and all the rest? Then why need we explain, deny, and apologize when such measures are proposed, if they be construed to work for our benefit and make our profession more profitable and its practice more pleasant, even though these measures were conceived with no such end in view? I therefore believe that it is advisable that this society urge upon its members, and the members of the profession throughout the State, that they use their influence with their legislators and in the several communities in which they live, in favor of such a law by our State legislature as shall give protection to the citizens from impostors in medical practice; and esteem it no disgrace, if it operates to protect the business of their profession at the same time that it saves their patrons' purses, their health, and often their lives."

Dr. Caldwell moved that a committee of three be appointed on the president's address, of which Dr. McCleary, of Indianola, shall be chairman. The chair appointed Drs. McCleary, Hill, and Caldwell.

After transacting the preliminary business, the following papers were read as per programme:

"Report of Committee on Medicine," S. B. Chase, Osage, chairman; "Acute Catarrhal Pneumonia, a Primary Disease," G. E. Crawford, Cedar Rapids; "Contusion of the Brain from Contra-coup—a Contribution to Cerebral Localization," J. H. Green, Dubuque; "Glucose," W. D. Middleton, Davenport. Dr. Middleton gave an interesting account of the manufacture of this product, and suggested that as an article of food in certain conditions of mal-nutrition from an inability on the part of the liver to convert the food into grape

sugar, this digested product, glucose, might be used to advantage. He gave some clinical facts coming under his observation, confirmatory of his suggestions.

D. W. Smouse, of Des Moines, read a paper on "Locomotor Ataxia, with Case," detailing a case he had under treatment, the result being that the case was going from bad to worse.

R. J. Farquharson, Secretary of the State Board of Health, read an interesting though very lengthy "Report on Hygiene and Sanitary Science."

A. W. Cantwell, of Davenport, read a "History of the Davenport Board of Health from its Organization."

Robert McNutt, of Des Moines, read an exhaustive paper upon "Ethnic Forces," which presented some curious facts in relation to the hybridity of races as a cause of physical and mental decay. He begins away back in the dawn of human history and the mists of antiquity, and seems to adopt the views of Haeckel that primitive man lived upon the earth 100,000 years ago—that the various types of mankind are exceedingly persistent, and do not diverge or change their ethnical characters to any perceptible degree during tens of thousands of years, no matter to what opposite extremes of climate and food they may have been subjected. He would, therefore, class the leading types as not having had a common origin. That the inferior races—the negro, the Dravid, and the Mongol—had long precedence on the earth before the Aryan appeared; that the Aryan is the only true historic and progressive race, and that little or nothing can be expected of the side-races in working out the great problems of civilized life.

He shows that the Aryan colony that pushed its way east into India made remarkable progress while the stock was kept pure, but in time they absorbed Dravidian blood, and fell, as a consequence, into that degenerate condition witnessed at the present day.

Egypt, the cradle of the sciences, was also an exceedingly progressive country while the Khamitic white blood was pure, but, absorbing the taint of the African, lapsed into a stationary condition, and then decay and ruin. He claims that the Malay and the Mound-builders and the hunting Indian are hybrids or crosses between the original Mongol and Dravidian, possessing the bad qualities of both races, similar in physical and mental characteristics, being *morose* and *brutish* in their nature.

He classes the African as the oldest of the races, and nocturnal in habit, and a natural born rapist. He shows that this type, when crossed with pure Aryan stock, produces the worst specimens of humanity, both as to diseased and debilitated physical conditions and horrid mental depravities. He shows from the reports of the penitentiaries of Virginia and Louisiana and Missouri, that this hybrid population furnishes the great bulk of the criminal class in the states where the African is numerous. He then gives the pure Aryans of the great republic of the west a gilded painting of their wonderful progress in useful inventions and their advancement in arts, sciences, and law, and thinks that it will continue in the onward march for ages to come, provided the Aryan stock can be kept pure.

He suggests that the law-making power should

decree any attempt at miscegenation as the highest crime against the state and against the nation. It was punished as a capital crime in India, but in time it failed to save them, and they were utterly lost.

S. B. Thrall, of Ottumwa, read a very practical and suggestive paper upon "Boards of Health and Contagious Diseases."

M. G. Sloan, of Dexter, reported a case of "Perityphlitis."

G. P. Hanawalt, of Des Moines, read the following paper on "Bichloride of Mercury in Surgery, in which he said:

"How gladly will we welcome corrosive sublimate, which, in the language of Dr. Neer, of New York, is 'antiseptic more potent, safer, not volatile, and easily obtained everywhere.' The reading of the excellent paper by the above-named gentleman in January last, preceded by a conversation with his estimable partner, Dr. Henry Abbe, of New York city, on the subject now under consideration, caused my first experiments in the use of this, to me, new antiseptic, since which time it has been my standard, and has yet to disappoint.

"An idea of the germicidal property of bichloride may be gained from the fact that the recent developments of Koch in Germany, and of Dr. Sternberg in our own country, prove beyond doubt that in a fluid literally creeping with bacteria the organisms were quieted by adding $\frac{30}{1000}$ ext. of the salt, while $\frac{20}{1000}$ part ended all activity present and future. The fluid thus treated failed to produce putrefaction in other organic solutions. Acting on this wonderful statement as to its antiseptic and germicidal qualities, Dr. Thallon, of Brooklyn, N. Y., adopts the use of the bichloride internally in the various forms of diphtheria, contending, with much reason, sustained by clinical proof, that a quite sufficient quantity may be taken into the system with entire safety to destroy, or at least to greatly modify, the septic process in the blood in this terrible disease. It is well worth a trial, for we all know with what feeling we regard the invasion of septicæmic symptoms—the feeling of being far out at sea, with neither compass, book, nor anchor.

"And now as to method in surgical use. A solution containing gr. viij. to Oj. of water, or what is better, eight grains dissolved in strong alcohol, and added to a pint of water, is about $\frac{1}{1000}$ in strength and about the proper strength for general use, although this may be varied considerably, $\frac{20}{1000}$ being doubtless strong enough for most cases.

"Supposing that a compound fracture is to be treated; of course the parts are to be cleansed and adjusted (I mean really cleaned and scrubbed—shaved, if need be, and scoured—under an anæsthetic if required; for if ever cleanliness is well repaid it is in the grateful appearance of comfort about a clean compound fracture as compared with a dirty one), then thoroughly bathed with sponges that have been soaked in and squeezed out of the above solution. Every bit of dirt, blood, etc., should be mopped out, being careful to remove any useless fragments of bone or soft tissues, carefully bringing all parts as nearly to proper place as may be, and adjusting the limb upon whatever splint may be chosen, first envel-

oping the injury in oakum, absorbent cotton, or 'cheese cloth' (which has previously been wrung out of the bichloride solution) laid about in even layers, so as not to disturb by unequal pressure; the whole to be surrounded by a thin roller of 'crinoline,' or gauzy material, likewise treated with the solution. This dressing is to be let alone until the oozing from the wound is seen on the outside of dressing, at which time, if there is no marked increase in temperature, a few layers of fresh dressing may be applied without disturbing the original, and then left again for a day or two, when the dressing, sutures, and drainage-tube (if any have been used) may be removed, and a dressing, similar to that used at first, may be applied; and, in most cases, may be left alone for a considerable length of time, some even for twenty, thirty, and even more than forty days, if we are to credit the statements recently published; but I would not advise, much less practice, this continuous delay in removing dressings, as beyond ten or fifteen days 'tis thought that danger from septic complication has passed, and there is nothing gained by clinging to stale dressings when clean and fresh ones may be applied easily and with great comfort to the patient.

"If an amputation has been done, the vessels are to be secured with catgut ligatures, which have been thoroughly soaked in the solution of bichloride, then kept in absolute alcohol until used—the stump is to be cleaned of every speck of blood and debris of every kind, by thoroughly wiping and pressing with the purified sponges and solution, as in case of fracture. After all oozing has ceased (and not before), the flaps are to be approximated carefully and united by the continuous suture—using the finer catgut, if choice can be made, treated as in case of ligatures—leaving ununited space only at proper places for the ends of the drainage-tube. The stump may then be literally slushed with the $\frac{1}{1000}$ or $\frac{20}{1000}$ solution by means of a fountain syringe fitted to the projecting end of the tube, and kept running until the liquid comes through unstained.

The stump, including ends of tube, may be covered by ample layers of well-picked oakum, jute, cotton, or soft thin fabric of any kind, and well bound with a thin roller, all of the dressing having previously been treated with the favorite solution. This thin and gauzy bandage is made use of because its light texture is not only comfortable to the patient, but allows the surgeon to detect the slightest oozing from the wound, thereby being able to decide when his dressing should be removed.

"Perhaps the best time to remove the drainage-tube will be on the third or fourth day, when this may be done, leaving the sutures and ligatures to take care of themselves, which, if catgut has been used, prepared as directed, need give the surgeon no uneasiness, as they will readily absorb, leaving nothing to be removed as in the case of wire or silk. If at this time the dressings have become saturated by discharge, or if patient's temperature has materially increased, a clean dressing throughout, much like the first, may be applied—but if there is little or no stain through outer dressing, and especially if comfort is the prevailing feeling, the drainage-tube alone is to be removed, and no further disturbance of

parts or dressings made for three or four days, perhaps longer.

As to toxic effect by absorption of this solution, the nearest I have seen was an attack of diarrhoea, possibly attributable to dressing, in a weak girl after amputation at middle of thigh, which, however, was rapidly cured without abandoning the dressing.

Dr. Weiss states that beyond a slight irritation about the edges of the wound, he has not not seen anything like poisonous effect from the use of this solution. This record will surely compare favorably at least with any of the well-known antiseptics.

Instruments may not be dipped in this solution on account of its well-known corroding or marring tendency—a one-twentieth solution of carbolic acid being much better for that purpose. Dr. Abbe mentions the fact that immersing the hands alternately in solutions of carbolic acid and bichloride causes a dirty blackish deposit in the crevices of the skin, which is readily removed by washing in a very weak solution of muriatic acid.

In conclusion, it may not be amiss to refer to the well-known virtues of this solution as a gargle—alike in diphtheritic or specific lesions of mouth and throat—and also to the testimony of leading dermatologists as to the satisfactory result of its use in an acne.

If, then, to its well-known virtues as a general remedy, we add potency, cleanliness, and trifling cost, as an antiseptic, deodorizer, and germicide, we are not far from an ideal "up-to-date" drug.

Dr. W. F. Peck differed from the paper, holding that perfect cleanliness and nature would ordinarily do away with any necessity for the use of antiseptics.

D. C. Brockman, Marengo, read a paper on "Improved Jacket Brace for the Treatment of Spinal Curvature."

"Leprosy" was the subject of a paper read by R. J. Farquharson, Des Moines.

Henry Ristine, of Cedar Rapids, reported a case of "Nerve-stretching;" and C. M. Hobby, of Iowa City, a case of "Malignant Degeneration of Benign Tumors."

J. Williamson, of Ottumwa, presented a report as chairman of section on "Obstetrics and Gynecology."

Jennie McCowen, of Davenport, read a paper upon "Insanity in Women," which she concluded by saying:

"We are gradually being emancipated from the habit of viewing mind as a mysterious, intangible entity, the sequences of which, in both normal and abnormal states, might be evolved from the inner consciousness of the observer, and are beginning to accept the more rational theory that (whatever the nature of mind) its manifestations take place through the nervous system, and the derangements are the result of nervous disease, to be studied by the same methods of investigation as other nervous disease; that insanity is not a metaphysical entity, but a disease of the nervous system manifesting itself by physical as well as mental symptoms.

"I can but think that the future of psychology is to come through a more careful study of the relations subsisting between physical conditions and mental states—not the abstract acceptance

of the theory merely (which is not a new one to the profession), but the practical and painstaking application of it to individual cases. And as the hospital physician rarely sees the disease in its earlier stages, the experience and observation and study of the general physician as well, is necessary in order to arrive at the whole truth.

"A disease which deprives a man of his rights and privileges as a member of the community in which he lives; of his right to manage his own business affairs in his own way; of his right to testify before a judicial tribunal; of his right to liberty and the pursuit of happiness according to his own methods; of his right to the enjoyments of home, to the society and care of his family, to himself; a disease which tends neither to recovery nor to death, but to chronicity—during which its subjects cease to be producers and become consumers through long periods of years; a disease which year by year seems to increase in frequency and at the same time to yield less readily to treatment, may surely claim from us the most careful study by the most approved methods known to the profession."

An excellent practical paper on "Obstructive Dysmenorrhœa" was read by G. O. Morgridge, of Muscatine, and one on "Uterine Therapeutics," by Robert Stephenson, Centerville.

A paper detailing the treatment of a case of "Stricture of the Esophagus" was presented by E. W. Clark, Grinnell.

H. B. Young, of Burlington, made a report on "Ophthalmology and Otology," and he was followed by a paper by F. E. Crittenden, Des Moines, on "Treatment of Obstruction of the Lachrymal Canal."

J. K. Gardner related his experience with the new hypnotic, "Paraldehyde."

The following report was made by the Committee on School Hygiene:

The undersigned, your committee to whom was referred the subject of school hygiene, for the purpose of calling the attention of the State Board of Health to some of the more important defects in the present methods of educating children, often brought to our notice as physicians, respectfully submit the following report:

WHEREAS, The attention of this society having been directed to the imperfections in the location, construction and arrangements of school buildings; also to the management of pupils by parent and teachers; therefore,

Resolved, 1st. That ample play-grounds, with proper shade and drainage, should be carefully considered by school boards.

Resolved, 2d. That school houses should not be more than two stories in height, that the rooms should be supplied with abundant means for supplying fresh air and ventilation, so as to secure an equable temperature at about 70° F. Furthermore, that the stairs should be wide but not steep, and the doors for egress should be large enough and open outward.

Resolved, 3d. That desks should be so arranged that the light will be introduced on the left side if possible, upon the right side, or from behind, but never so as to strike pupils squarely in the face.

Resolved, 4th. That we condemn the practice of sending children to school before they are seven

years of age; also the tendency to the "cramming" process which so often checks, rather than promotes, physical and mental development. Again we urge greater discretion on the part of parents about putting children into school in special cases, when the health is imperfect, or where the child is remarkably precocious.

Resolved, 5th. That this Society request the State Board of Health to take some action to bring this subject to the attention of the State Superintendent, the County Superintendents, and Boards of School Directors.

Resolved, That the Board of Health should also make known the facts collected and tabulated, regarding the increase of diseases of the eye in school life; also, impart instruction in the methods by which this organ is relieved of the excessive strain which modern civilization makes upon it.

Wm. Watson, H. A. Gilman, George F. Jenkins, G. H. Hill, E. H. Hazen, Committee.

The following is the list of officers, the standing committees, and the representatives of the Society to the American Medical Association for the ensuing year:

President.—H. C. Huntsman, Oskaloosa.

First Vice-President.—H. B. Ransom, Burlington.

Second Vice-President.—C. C. Griffin, Vinton.

Secretary.—J. F. Kennedy, Des Moines.

Assistant Secretary.—G. E. Crawford, Cedar Rapids.

Treasurer.—G. R. Skinner, Cedar Rapids.

Place of Meeting.—Cedar Rapids, on the third Tuesday of May, 1885.

Committee of Arrangements.—H. Ristine, Cedar Rapids; C. M. Hobby, Iowa City; A. B. Reed, Cedar Rapids; W. E. Egan, Atlantic; G. R. Henry, Burlington.

Committee on Publication.—J. F. Kennedy, L. C. Swift, Des Moines; W. D. Middleton, Davenport; J. Williamson, Ottumwa; G. R. Skinner, Cedar Rapids.

Committee on Necrology.—First district—J. A. Scroggs, Keokuk.

Second district—A. W. Cantwell, Davenport.

Third district—S. N. Pierce, Cedar Falls.

Fourth district—L. P. Fitch, Charles City.

Fifth district—W. C. Schulze, Marengo.

Sixth district—E. W. Clark, Grinnell.

Seventh district—W. H. Ward, Des Moines.

Eighth district—P. Llewellyn, Clarinda.

Ninth district—J. D. Holmes, Audubon.

Tenth district—J. A. Meredith, Ames.

Eleventh district—G. W. Briggs, Sioux City.

Committee on Ethics.—S. E. Robinson, West Union; J. D. McCleary, Indianola; A. W. McClure, Mt. Pleasant; P. S. Mosher, Boone; W. S. Robertson, Muscatine.

Delegates to American Medical Association.—First district—Dr. J. Maxwell, Keokuk; Dr. Scroggs, Keokuk; Dr. Stever, Fairfield; Dr. A. A. Gillman, Mt. Pleasant.

Second District—Dr. Adair, Anamosa; Dr. W. S. Robertson, Muscatine; Dr. A. B. Bowen, Maquoketa; Dr. W. D. Middleton, Davenport.

Third District—Dr. Wm. Watson, Dubuque; Dr. G. B. Wood, Fairbanks; Dr. D. M. Wicke, New Hartford; Dr. S. N. Pierce, Cedar Falls.

Fourth District—Dr. A. D. Bundy, St. Ansgar; Dr. Gardner, New Hampton; Dr. D. S. Brainard, Stacyville; Dr. S. B. Chase, Osage.

Fifth District—Dr. S. S. Lytle, Iowa City; Dr. G. R. Skinner, Cedar Rapids; Dr. D. C. Brockman, Marengo; Dr. C. C. Griffin, Vinton.

Sixth District—Dr. G. P. Clarke, Prairie City; Dr. S. B. Thrall, Ottumwa; Dr. J. R. Gorrell, Newton; Dr. H. C. Huntsman, Oskaloosa.

Seventh District—Dr. M. G. Sloan, Dexter; Dr. L. H. Sweber, Colo; Dr. G. P. Hanawalt, Des Moines; Dr. E. T. Likes, Winterset.

Eighth District—Dr. J. B. Wilson, Creston; Dr. L. S. Graves, Afton; Dr. P. W. Liewelling, Clarinda; Dr. W. H. Gibbon, Chariton.

Ninth District—Dr. W. E. Egan, Atlantic; Dr. J. E. Sanson, Anita; Dr. C. H. Pinney, Council Bluffs; C. W. DeMotte, Shelby.

Tenth District—L. J. Alleman, Boone; D. S. Fairchild, Ames.

Eleventh District—J. D. McVay, O. D. Donley, G. H. Grimmell, Charles Enfield.

The committee recommended that the incoming president have the power to fill all vacancies on committees and delegations, and to send delegates to neighboring state medical societies.

FACETIOUS.

S. E. Robinson, for — Guthrie, offered the following resolution, which was unanimously adopted:

Resolved, That the Legislature of the State of Iowa be requested to frame a law making it obligatory that the formulary of patent medicines and proprietary medicines be printed on the inside labels of the package or bottle, so that an antidote for such poisons may be had in time to save the patient.

After the induction of the new officers into their respective stations, and the usual votes of thanks, the final reports of the officers were presented.

A. Von Mansfelde, the efficient Secretary of the Nebraska Medical Society, was present during the entire session, and contributed largely to the interest of the sessions by his participation in the discussion of several papers.

Thomas Siveter, who had been carried on the *mortuary* list of the society for several years, was present, and made several interesting little speeches. He was one of the organizers of the society, and is 85 years of age, and bids fair to become a centenarian.

There were from eight to twelve lady physicians in attendance. Their respectful attention, punctual attendance upon all the sessions, modest demeanor, and lively interest in all the papers and discussions, won for them all the profound respect of the sterner sex, and may have had something to do in leading several members to remark that not on any occasion was any member thought to be under the influence of intoxicants.

Illinois State Medical Society.

At the meeting held in Chicago, May 20, 21, and 22, the following officers were elected for the ensuing year:

President.—Dr. Daniel S. Booth, of Sparta.

Vice Presidents.—Dr. S. C. Plummer, of Rock Island; and Dr. W. T. Kirk, of Atlanta.

Treasurer.—Dr. Walter Hay, of Chicago.

Secretary.—Dr. S. J. Jones, of Chicago.

Assistant Secretary.—Dr. H. B. Buch, of Springfield.

South Carolina Medical Association.

Officers for the ensuing year:

President—Dr. A. A. Moore, of Camden.

Vice-Presidents—Drs. C. Kolloch, of Cheraw; James Evans, of Florence; and T. J. McKie, of Woodlawn.

Recording Secretary—Dr. John Forrest, of Charleston.

Corresponding Secretary—Dr. H. D. Fraser, of Charleston.

Treasurer—Dr. H. W. DeSaussure, jr., of Charleston.

The Association meets in Charleston, April 23, 1885.

West Virginia Medical Society.

Officers for ensuing year:

President—Dr. George Baird, of Wheeling.

Vice-Presidents—Drs. T. A. Harris, of Parkersburg; R. R. Frey, Terra Alta; and S. H. Austin, of Lewisburg.

Treasurer—Dr. John A. Campbell, of Wheeling.

Secretary—Dr. S. L. Jepson, of Wheeling.

Board of Censors—Drs. J. H. Manown, L. C. Hunt, J. H. Brownfield, J. O. Wall, J. M. Bowcock, W. J. Bland, and D. W. Allen.

Weston was selected as the place of meeting for next year's session.

American Climatological Association.

At the meeting held in Washington, May 3 and 5, the following officers were elected for the ensuing year:

President—Prof. A. L. Loomis, of New York.

Vice-Presidents—Drs. F. I. Knight, of Boston, and W. H. Geddings, of Aikens, South Carolina.

Secretary and Treasurer—Dr. J. B. Walker, of Philadelphia.

Council—Drs. J. H. Tyndale, of New York; E. T. Bruen, of Philadelphia; E. D. Hudson, of New York; Frank Donaldson, of Baltimore; Beverly Robinson, of New York.

California State Medical Society.

At the meeting held in San Francisco, April 16 and 17, 1884, the following officers were elected for the ensuing year:

President—R. Beverly Cole, San Francisco.

First Vice-President—W. S. Thorne, San Jose.

Second Vice-President—W. P. Gibbons, Alameda.

Third Vice-President—A. H. Agard, Oakland.

Fourth Vice-President—H. J. Crumpton, Lakeport.

First Assistant Secretary—Dr. Powell, Marysville.

Second Assistant Secretary—Mrs. L. M. F. Wanzur, San Francisco.

Treasurer—F. W. Hatch, Sacramento.

Texas State Medical Society.

At the sixteenth annual meeting held in Belton, April 22, 23, 24 and 25, the following papers were read:

"Evolution," by Dr. R. W. Park, of Waco;
"The Mineral Waters of Texas," by Dr. J. M. Willis;
"Periosteum Grafting," by Dr. C. M. Trueheart, of Galveston;
"Animal Ligatures," by Dr. H. W. Dudley, of Hillsboro.

Officers for the ensuing year:

President—Dr. H. C. Ghent, of Belton.

Vice-Presidents—Drs. E. P. Becton, of Sulphur Springs; H. H. Darr, of Caldwell; and M. Matkin, of Hearne.

Secretary—Dr. W. J. Burt, of Austin.

Treasurer—Dr. J. Larendon, of Houston.

The Association meets in Houston, Texas, on the fourth Tuesday in April, 1885.

Lack of Refinement in the American Medical Association.

A resident of Washington writes to the *N. Y. Med. Jour.* as follows: "The usual disgraceful performances took place at the receptions. Mrs. L. generously opened her beautiful house, and provided as fine a table as Demenet could serve. She was rewarded by having men stalk in (hats on their heads) from the front room to the dining-room, where they fought like wolves for places at the tables, overturning piles of plates, breaking her expensive ornaments, and soiling her rugs with pools of tobacco-juice."

We all know that a small army of hangers-on attend the meetings of the American Medical Association, and that most of these fellows manage to get cards admitting them to the receptions, where their boorishness tends to bring the Association into discredit. In view of these facts, it seems to us that the interest of the profession would be furthered if measures were taken to put a stop to the admission of these interlopers.

Items.

—Medical London has been exercised over the fact that John Bright, who has been ill, called on a homœopath to attend him.

—The published report of an English benevolent society says: "Notwithstanding the large amount paid for medicine and medical attendance, very few deaths occurred during the year."

—At a meeting of the Cincinnati Medical Society, March 25, Dr. Sattler said that while no bacilli were found in the breath of phthisical patients, yet plates of glass covered with glycerine and hung in consumptive wards became covered with bacilli.

QUERIES AND REPLIES.**EDS. MED. AND SURG. REP.—**

Will you or your many readers, through the MEDICAL AND SURGICAL REPORTER, give a treatment for a case that has resisted all therapeutic efforts? The patient, about one year since, had syphilis, though now no symptoms remain. About two months since, after sexual intercourse (and even at longer intervals without it) the penis is seized with intense itching, which is followed by small vesicles that contain serum. These dry up and there is no more trouble until another act of coition or the elapse of several weeks without the act. I have used various local applications, and iodide potash, mercury, arsenic constitutionally. Mc.

DEATHS.

DAY.—In Mechanicsburg, Pa., Monday, May 12, 1884, after a short illness, Dr. Alfred Day, in the fifty-fifth year of his age.

THE MEDICAL AND SURGICAL REPORTER.

INFLAMMATION OF THE EAR, AND ITS RELATIONS TO WHAT IS COMMONLY CALLED "TAKING COLD."*

BY BENJ. J. RUDDEROW, M. D.,
Of Philadelphia.

In presenting my paper this evening, it is not as an expert nor to specialists in this branch of medicine that I wish to speak, but to place before the general practitioner some few points that may help prevent some of the bad results which are so frequently met with as coming from the tardy, timid, or ignorant management of such ear affections as arise from an ordinary catarrh, or that happen as one of the complications of sore throat, measles, or scarlet fever. It is from the so-called taking cold that we find many of the acute or middle-ear diseases arising. When one is attacked with a cold, or has a more or less acute catarrh, it is generally traceable to a sudden or unexpected fall in temperature, or the exposing of a limited portion of the body to moisture, or it may be the cooling effect of air in motion, or the depressing effect of air overheated or impure in assembly rooms, dormitories, etc. It often happens that the best conditions of ventilation and heat cannot be had; then how may the body be prepared to not only withstand the inevitable exposure, but to make a draught of air one of pleasure and one of health?

Living as we ordinarily do, without a sufficient amount of active exercise out of doors, the sur-

face of our bodies becomes morbidly sensitive to those influences that produce an acute catarrh. Thus one finds amongst people great dread of a draught, and the average person will rather incur the risk of contracting a fever or some contagious disease in a crowded vehicle or assembly than that he should have these places freely ventilated. By far the greater majority of mankind, while resting, consider air in motion to be one of the most morbid influences that one may meet. It is this, I think, that presents us many obstacles in the way of properly ventilating public vehicles and buildings. We do not, I think, find many persons so educated as to endure, when at rest, air in motion, far less to find pleasure and health from it.

But I speak from experience when I say that it is very easy to overcome this morbid sensitiveness and often fatal tendency to become an easy victim to the causes of a common cold. But how may one teach himself to endure a draught and lessen the tendency to catch cold? By first diminishing the morbid sensibility of the body to catch cold, and this can best be brought about by a graduated exposure and friction of the skin in a daily air- or sun-bath, to be followed by such local sponge-baths as one may be able to react from speedily. For this reaction to be speedy and spontaneous, it is necessary that the temperature of the water should not be much lower than 80° Fahr.

With the first air-bath it is well that the body should be exposed but for a short time only, as, for instance, the time taken to walk briskly across an ordinary bed-chamber. Soon, by a little practice in this way, the time of exposure may be

* Read before the Philadelphia County Medical Society.

prolonged to fifteen or twenty minutes, and temperature of the bath used accommodated to that of the outer air. The healthful effects of these exposures may be still further increased by two or three deep, chest-filling inspirations, with closed mouth, and by few such movements of the arms as would tend to invigorate the chest-muscles and quicken somewhat the action of the heart. About four times a week, before any water is applied, and while taking the air-bath, the whole surface of the body should be briskly rubbed till there is a sense of glow and warmth of the skin, with hair-mitten, flesh-brush, or coarse towel. These exercises should at first be of short duration, and more especially so if the heat-producing powers of the body are low. Also, if the subject be not too feeble, the rubbing should be done by himself rather than by another, as it is thus made more beneficial. These exercises should, in all cases, not be attempted in winter, except in a sunny room or one heated artificially.

We should bear in mind that the object of our treatment is to make the body less morbidly sensible by the exposing of the entire skin surface daily to air, light, friction, and cleansing, in an atmosphere nearly like the prevailing temperature. These daily air-baths should not be indulged in for too long a time, nor yet should invalids indulge in the full practice at once, but enter upon it deliberately and cautiously, as one not knowing how to swim enters the water gradually. These few hints, with the cautions given, will, in a few weeks, make almost any one not only less susceptible of taking cold, but better in every way; but at the same time I do not wish it to be understood that by training the body to be less susceptible to the sudden changes in temperature, that one may with impunity, without hat or coat, stand exposed to a northeaster.

In the preventive treatment of catarrhal affections of the middle ear, food, clothing, and exercise are hygienic factors that have important relations in the causation of catching cold. Alcoholic stimulants, even in moderate doses, do increase the liability of taking a cold, and one who has been deluded by the idea that by so doing he can keep out cold, had best immediately put on an additional covering to keep his animal heat in. As a rule, except in certain conditions, alcohol is a very bad food, and what those conditions are has not as yet been determined with anything approaching an agreement by even the most learned chemists and physiologists. Articles of food that help produce dyspepsia, such as greasy fries, hashes, and other messes found on the tea and

supper table, so fearfully and wonderfully made, should be avoided. Train the stomach and digestive organs to be the servant, not the master; keep them in vigorous action by the use of coarse farinaceous foods and milk. The farinaceous articles of food contain not only many tissue-building ingredients that are indispensable, but in a mechanical way, by their contact with the digestive organs, do a work similar to that which friction of the skin does for the surface of the body in hastening the desquamation of effete and sticky epithelium and the cleansing of the follicles.

Let the breakfast be one of thoroughly boiled farinaceous food, eggs, milk or cream, and fruit; a light lunch of fruit, or milk and bread; dinner hearty, but free from condiments and spices, including fish, meat, and vegetables; the tea somewhat similar to the breakfast. As to clothing, flannel should be worn next the skin, day and night, by persons of all ages. The notion that one can toughen children by insufficient clothing and a promiscuous diet, is a fallacy, as we all know.

We often meet people, otherwise intelligent, who keep the legs and chest of their children bare, and go themselves without flannels from the supposed good health of savages and paupers. The flannels worn by day should be changed at night, and when taken off should be turned inside out and allowed to dry and air thoroughly. The neck-ties and bands should be loose, so as not to check the return circulation in the neck; the foot-covering thick, loose, and low-heeled, with a broad sole, allowing the interosseous spaces room, so as not to press on the nerves and vessels that vivify the toes.

From the preventive measures, we will pass to some of those conditions which demand promptness on the part of the medical practitioner in his effort to cure the external or middle ear inflammation at the earliest moment. It is not necessary to systematically go over the various diseases, my purpose being to give a few points that may be of use to the general practitioner, and not my views or opinions as an expert.

Every medical man should be able to distinguish the drum-head or tympanic membrane, and any one who can introduce a catheter can incise a drum-head. Ear-ache, generally badly treated, arises commonly in the beginning from one or two forms of ear disease, either inflammation of the dermoid or periosteal lining of the external auditory canal, or an acute inflammation of the middle ear. Pain and deafness often occur in the course of common boils in the external auditory

canal. How is one to make the distinction between such a disease or something deeper seated. Each one should make himself so familiar with the external auditory canal as to tell at sight, whether a given canal is changed in calibre or not; and if changed, what is the nature of the change. Inspect the canal, and with a probe, guarded with a piece of cotton, explore it thoroughly, carrying the probe around its entire circumference, touching each segment. In this way one can ascertain whether there is a focus of local inflammation, and having found it, then with a sharp, curved bistoury, incise clear down to the bone. The earlier this is done the better. After the incision is made, foment the ear with warm water from a fountain syringe; poultices in these cases are to be avoided, as the uninterrupted application of heat tends to beget œdema, making the canal more or less boggy, thus helping to produce a successive crop of boils, or setting up an obstinate or diffuse inflammation. If incision should do no good, apply one or two leeches in the hollow, at the base of the tragus, half an inch in on the front wall of the external auditory canal. Two or three leeches applied in the position mentioned I have found to do more good than when applied in front of the tragus, or over the mastoid, except there be an inflammation of the mastoid cells, commencing to outcrop behind the external ear.

Persons consult us in reference to pain and deafness in the ear; they tell us that they have had a cold, a sore throat, or have been using a nasal douche; their rest has been broken, they have had continual pain and agony; what are we to do—order a poultice, and give an anodyne to relieve the pain, or, if in the case of a child, tell the parents to apply a poultice and await the discharge of pus? It is just such cases treated in this way that go to make up a large bulk of incurable cases of otorrhœa; they are the ones that worry the aurist by their obstinate character, and end in temporal or bone disease. When consulting a patient suffering as above, act promptly. Take the hearing distance with the watch, examine the auditory canal, and see that there is no inflammation there external to the drum-head. Apply leeches inside the hollow of the tragus, favor bleeding by hot fomentations, and if the pain and deafness are not relieved within a few hours, incise the drum-head with a fine straight knife or bistoury. Carry the incision from just below the extremity of the long process of the malleus to the lower border of the membrane. After this has been done, inflate the ear with a Politzer inflator, or get the patient to hold his nostrils closed

by means of his fingers, and then blow strongly with closed mouth into the nostrils.

Syringe the ears with a warm solution of salt and water, carbonate of soda, or boracic acid. This syringing with warm water is objected to by many. After the syringing give your anodynes; not before, as the relief given before the incision may mask the processes going on in the ear, and stupefy your patient until something bursts, that meaning generally a more or less hopeless rent in the membrane, or, this not happening, a thorough invasion of the mastoid cells. Repeat the leeches, if necessary, and the paracentesis, to cut short the inflammation. Though the paracentesis should be done every day for a week or more, one need not not be afraid, I think, of injuring it, as it will not do as much harm as to leave the products of inflammation dammed up in the drum-cavity, to destroy by their macerating process the machinery, threaten the portals of the internal ear, stuff the mastoid cells, or break through a more or less disorganized ear-drum. As a rule, persons suffering with ear-ache need not be kept indoors except for a few hours, unless in bad weather. Moderate walking appears to lessen the pain, and seems, whether from the posture of the body or the influence of that form of locomotion upon the circulation in the head, to quicken the healthy process of resolution. Give the anodynes when the pain is severe, and encourage the sufferer to walk about slowly until a decided sleepiness is induced. But the principal object in this stage of the disease is to keep a free opening through an artificial drum opening, in order to allow of the escape of all inflammatory products. See the patient every five or six hours during the first two or three days; and whenever it appears that the opening has closed that has been previously made, repeat the paracentesis. If the opening previously made should be closed, if possible, pass your knife through it; but if that cannot be done, then make an incision through the lower part of the drum, below the malleus.

Morphia, chloral, and bromide of potassium, to relieve pain, often a large dose of bromide, with a hypodermic, will produce happy results. Some form of magnesia salts is, I think, an admirable laxative, or the bitter water alone, or with hot water, a gill or two of the former to a pint of the latter. Let the diet be nutritive, especially in the early part of the day; but as the pain occurs mostly at night, it is best not to fill the stomach at that time.

One cannot be too prompt in evacuating the middle ear when there is an inflammation of that

part. Delay is dangerous, and the paracentesis does no harm.

In measles and scarlet fever, examine the ears daily, and anticipate, if possible, the ulceration of a tympanic membrane, which so frequently occurs in the progress of these diseases. If the general practitioner would only examine daily the ears of those afflicted with scarlet fever or measles, and, finding them inflamed, treat them promptly, a great number of those obstinate or incurable otorrhœas and middle-ear troubles met with would be prevented.

No practitioner is really prepared to treat a case of scarlet fever or measles who is not able, at least, to recognize the drum-head when he sees it, and to perform the simple operation of paracentesis.

ON PAROXYSMAL FEVER—MOT MALARIAL.*

BY J. H. MUSSER, M. D.,

Physician in charge of the Medical Dispensary of the Hospital of the University of Pennsylvania; Pathologist to the Presbyterian Hospital.

That non-malarial intermitting fever is of frequent occurrence few will deny. Such cases have come to the writer's notice so often that, especially as but little can be found in reference to this subject in medical literature, arranged in a systematic manner, he has deemed it of the highest practical importance to record his observations, for the purpose of emphasizing the value of distinguishing these two forms of intermitting fever. In addition to the hurried narration of illustrative cases, a little time will be taken for the consideration of the mode of recognition of the many sources of origin of paroxysmal fever, and a moment given to the mechanism of fever. It will not be out of place, however, to make a brief reference to the writings of others in this connection, and first to that of the late Dr. Murchison.

In a most instructive clinical lecture,† he called attention to all the forms of paroxysmal fever, giving twelve varieties, viz. :

1. Malarious intermitting fever.
2. Certain cases of typhoid fever.
3. Certain cases of relapsing fever.
4. Pyæmia.
5. Fever from pent-up pus.
6. Fever from endocarditis, with or without embolism.
7. Tubercular fever.
8. Fever from lymphadenoma.

9. Syphilitic fever.

10. Urinary intermitting fever.

11. Hepatic intermitting fever.

12. Intermitting fever from morphia.

In addition to examples under each division, he pointed out the clinical features and points of distinction in such detail that it would be superogatory to enter upon such lines, save in the broadest manner, in this paper.

In the following pages, therefore, cases illustrating the second, fifth, sixth, seventh, and eleventh classes, respectively, of the above, will be recorded, and some new classes will be added, embracing cases of paroxysmal fever due to gastro-duodenal and pulmonary catarrh, to pent-up serum, to forming pus in a confined space.

Since this paper has been in preparation, a volume of the latest St. Thomas Hospital Reports (vol. xii., '81,) came into the writer's hands. Of the many able articles contained therein, there is one by Dr. Ord entitled, "On Some Cases of Pyrexia Simulating Ague." He records a case of ulcerative endocarditis, and one of jaundice with obstruction, attended by intermitting fever. Similar cases are detailed below, and hence it will not be necessary to more than refer to them. Cases III. and IV. of his list are very interesting, and worth repeating in abstract.

Case III. Female, æt. 58. Most of life in Mauritius. After returning to England suffered from what was called ague—shiverings, heats, and sweatings at irregular intervals. At first no pain, but finally increasingly severe pain, attended with vomiting, was felt in the left iliac region. The symptoms repeatedly recurred for months, and were regarded as outbreaks of latent ague acquired abroad. Treatment by quinia and arsenic. She finally, after a severe paroxysm, passed a stone the size of a bean from the bladder. Instant relief followed, and six months passed away (to time of writing) without any return of fever or sweating.

Case IV. is more remarkable, and for the possibility of its like appearing to us, it should be kept in mind.

Case IV. A man, æt. 30, never in the tropics, had daily attacks of high temperature, with shivering and sweating. He was sallow, worn, and emaciated. His liver was enlarged; his spleen not. He had syphilis. The fever would be reduced by quinia, but only for a time. Thirty grains of iodide of potassium daily cured him, the intermitting fever having been considered by Jenner, in consultation, a manifestation of syphilis.

I. The temperature curve of typhoid fever sim-

* Read before the Philadelphia County Medical Society.

† The causes of intermitting or paroxysmal pyrexia, and on the differential characters of its several varieties. *Lancet*, May 3, 1879.

ulates intermittent fever almost always at some period of its course. During the first week of the disease it is a difficult matter to decide whether a true intermittent is present or not, while in the decline of the disease a distinctly intermitting type is generally recognized. During the period of convalescence one must be watchful that the transient fever which so frequently develops, may not be considered malarial. The temperature during the course of typhoid fever, and the convalescence from it, is, as Dr. Cayley puts it, *labile*. It rises and falls with only the slightest provocation, and frequently takes on an intermitting type.

The following is a rare case of typhoid fever, in which the temperature at the height of the disease was distinctly intermitting. Dying the sixth day of observation, it was noted that four days before death the patient had daily a congestive chill, followed by a very high temperature. The temperature on the morning of the first chill was $101\frac{1}{2}^{\circ}$ (Fahr.); the evening, $104\frac{3}{8}^{\circ}$. The morning temperatures thereafter were, on the second, third, and fourth days, respectively, $96\frac{3}{8}^{\circ}$, $99\frac{3}{8}^{\circ}$, and $96\frac{1}{8}^{\circ}$, and on the corresponding evening hour $104\frac{3}{8}^{\circ}$, $105\frac{3}{8}^{\circ}$, and $106\frac{3}{8}^{\circ}$, the latter two hours prior to death. It was considered a case of congestive malarial fever. The autopsy revealed the lesions of typhoid fever about the twelfth day of the disease.

II. It is well known that the fever from pent-up pus is frequently, almost constantly, of an intermitting type. An empyema has frequently been overlooked on this account, but it has never fallen to the writer's lot to have a case that could not easily be recognized. It was different in other cases of deep abscesses, however, and notably in a case—the true nature of which, Murchison says, is almost always overlooked—a case of hepatic abscess.*

The patient, a male, thirty-nine years old, had lived on the Susquehanna, near Harrisburg, and had had chills and fever daily, three weeks prior to admission to the hospital. When admitted, he did not seem very sick; he had walked to the hospital, and was permitted to be up each day. He was slightly emaciated, and his liver was enlarged. He had daily paroxysms of fever, but the sweating stage continued all night, being more prolonged than in malarial intermittents. He died of hemorrhage from the bowels, one week after admission. The hemorrhage was found to be due to extensive ulceration of the large intestine, not suspected during life, on account of the occurrence of constipation. In addition, at the

autopsy, a large abscess in the right, and two small ones in the left lobe of the liver were found.

The following table exhibits the temperature record, and shows that we should have considered more seriously the low febrile range:

	A. M.	P. M.
October 9	99°	100°
" 10	99°	101°
" 11	99°	$102\frac{3}{8}^{\circ}$
" 12	99°	$101\frac{3}{8}^{\circ}$
" 13	99°	102°
" 14	$99\frac{3}{8}^{\circ}$	101°
" 15	$98\frac{3}{8}^{\circ}$	99°

The history of residence in a malarious locality, the temperature record, the absence of marked local symptoms and of intestinal disorders, favored malarial intermitting fever; the absence of enlarged spleen and the low temperature range negated that fever.

A child was seen with a history of daily febrile paroxysms, suspected to be malarial. The child had a severe paroxysmal cough, however, and was losing strength and flesh rapidly. An examination revealed the physical signs of circumscribed pulmonary consolidation, and the mother related the swallowing of a tack some time previous. Ten days afterwards, after a paroxysm of coughing, the tack and a large amount of pus were expectorated. The hectic soon lessened, the resulting cavity rapidly closed, and the patient's health was restored. Another example of deep-seated abscess.

Abscesses developing near mucous surfaces are oftentimes very puzzling, at least in their early period.

An abscess of the prostate gland, in a man 48 years old, was one of the most difficult to discern. The patient had been sick a week, and when seen by the writer was in the midst of a febrile paroxysm. He had marked gastro-intestinal derangement, with dry, brown tongue, extreme malaise, daily febrile paroxysms, preceded by chilliness, and followed by profuse sweats, which continued in the night; in addition, a dullness of intellect was observed. Six days after the first visit urinary tenesmus was noticed, subsequently rectal distress; an examination revealed a distinct prostatic abscess. It is of interest to note that fever did not occur after the abscess had fluctuated, and hence that the forming stage of an abscess sometimes is attended with paroxysmal fever. The following exhibits the evening rise and morning fall, taken on different days:

13, 4 p. m., .	$102\frac{3}{8}^{\circ}$.
14, 4 p. m., .	$99\frac{1}{8}^{\circ}$, cinch. anticipated.
15, 12 m., .	102° , cinch. in lessened doses.
16, 12 m., .	$98\frac{1}{2}^{\circ}$, cinch. in increased doses.

*Trans. Path. Soc., vol. viii.

17, 11 a. m., . 98°, cinch. in increased doses.
 18, 5 p. m., . 103°, cinch. in again lessened doses.
 19, 9 a. m., . 98½°, . 5 p. m., 103°.

A febrile paroxysm was not detected after the 20th, and the table shows that cinchona merely prevented the paroxysms, but did not control them. The case was certainly difficult to analyze. The absence of enlarged spleen, the return of the fever after discontinuing cinchona, and the exhaustive sweats, repulsed the idea of malaria. The appearance of the tongue, the malaise, the headache, and the dullness of mind, with the fever range, made one consider typhoid rather seriously. On the sixth day (19th) after my first visit, the local symptoms defined the lesion. The febrile action then ceased, but the local inflammatory condition continued. It would probably explain the cessation of fever with complete suppuration to say that the soft tumor was not so much an irritant as the hard mass prior to pus formation.

(To be Continued.)

FACIAL ERYSIPELAS IN A PREGNANT WOMAN; RECOVERY.*

BY I. C. HAZLETT, M. D.,
 Of Belle Vernon, Pa.

I was called March 1, 1884, to see Mrs. S—, aged thirty-eight years, mother of eight children, from whom the following history was obtained:

On Thursday night, February 28, she noticed, on retiring, a slight sore on septum of nose.

Friday morning, February 29. Soreness a little increased, and a slight blush extending from sore to cheek, with some puffiness of the face during the day.

Saturday, March 1. Saw her at noon; found the face much swollen and inflamed; both eyes nearly shut; nose swollen entirely out of shape; tongue heavily coated; throbbing headache; temperature, 101° F.; pulse, 100.

My diagnosis was facial erysipelas, and on inquiry learned she had been enjoying the best of health, was well nourished, the bowels had been regular and free; but on further inquiry, she told me she expected to be confined in about two weeks.

Having always been taught to keep away from puerperal patients while attending erysipelatosus ones, those of you who have had the trial can judge of my feelings to find erysipelas in a puerperal woman. Gave her quinia sulph., gr. iv.,

every four hours; alternating with tr. ferri chlor., gtt. x., every four hours. Also, tr. aconite, fl. ext. belladonna, āā gtt. j., every hour in teaspoonful of cold water; the room to be kept quiet and at as even temperature as possible.

Sunday, March 2. Was called about 3 a. m., and told Mrs. S. was in labor. On my arrival, found the babe, a good-sized boy, had been born about one hour, but the secundines were still retained, and that rather a free, but not alarming, hemorrhage had taken place. I at once removed placenta, together with all soiled clothing, from the bed and from the room; found temperature normal, pulse 100, patient free from pain and resting easy.

Had the children's bed removed from the room, ordered all persons to be kept out of room except nurses, room to be well ventilated and still kept at an even temperature; all napkins used by my patient to be saturated with a 10 per cent. solution of carbolic acid, to be frequently changed, and to be removed from the room as soon as soiled. Continued the same treatment as the day before. Saw my patient at 5 p. m. Temperature 101½, pulse 100, appetite good. Continued quinia sulph. gr. iv. every four hours, tr. ferri chlor. gtt. x. every eight hours, alternating with potassic iodide gr. v. every eight hours. Continued aconite and belladonna every hour or two.

Monday, March 3, 7 o'clock a. m. Temperature 101½, pulse 100. Continued treatment of the day before, and saw her again at 5 o'clock p. m., and found temperature 102½, pulse 100, appetite good, swelling and flush beginning to fade and pass away.

Tuesday, March 4, 11 o'clock a. m. Temperature 102½, pulse 96. Erysipelas faded and the swelling leaving the face. Bowels opened freely, appetite good.

Saw my patient again at 5 p. m. Temperature, 104½°; pulse, 86; appetite good, but complains a little of dryness of the throat.

March 5, 9 o'clock a. m. Temperature, 99½°; pulse, 80. Erysipelas entirely gone; throat still dry; pupils a little dilated.

At this time, Dr. W., from Johnstown, Pa., a brother of my patient, saw the case with me. We stopped all active treatment and gave quinia sulph., gr. iv., every six hours, alternating with tr. ferri chloridi, gtt. x., every six hours, together with good, nourishing, easily-digested food.

At this time my patient began to talk a little incoherently, but was not stupid, and recognized any one on going to her bed.

Saw her again at 5 o'clock p. m. Temperature

*Read before the Fayette County Medical, Society.

99 $\frac{1}{2}$ °; pulse, 80; mouth still dry; inclines to talk, also to look and listen as if for some one calling; then will speak to some imaginary person on the bed or at the foot of the bed, or call to some of her children that are in danger, or in mischief, sometimes kindly, but generally in great earnest.

Thursday, March 6. Was called at 5 o'clock a. m., and told my patient was much worse. On my arrival, found temperature normal; pulse normal, but very restless and wild; had put in a fearful night, raving, crying, scolding, and pleading to be taken home. Her night clothes and underclothes, together with the sheet, were completely saturated with perspiration. She had passed no urine, but no accumulation could be detected. Gave potassic bromide, gr. xv., chloral hyd., gr. v., every half hour until sleep was produced. Stopped all other medicines; gave milk as often as I could get her to take it.

Six o'clock p. m. Temperature 97° F., pulse 76; has taken potassic brom. $\mathfrak{z}$ ij., chloral hyd. $\mathfrak{z}$ i. during the day, but no signs of sleep. Has taken no food in the last twenty-four hours, except milk, and says she will not eat any more until taken home. Is very wild, talks incessantly to imaginary persons about her, and frequently speaks of explosions that are taking place, even brushing the dirt from the bed-covers as it falls about her. Does not recognize any one on going to her bed, except her father, who came to see her at this time. No urine passed during the day, and much against my patient's will, with the assistance of four women, I used the catheter and drew off about thirty ounces of not unhealthy looking urine. Continued chloral and brom., and to each dose added about $\frac{1}{2}$ gr. morph. sulph., staying with my patient until three doses were given, watching the effect. At this time she ceased to talk so much, and would lie still for a few minutes at a time. Left a few morphia powders with directions to give her one every hour, with a dose of a mixture of chloral and brom. until she slept, then stop morph. and give mixture alone when she would awaken. At 10 o'clock, p. m. she slept, and continued to sleep most of the time until morning.

Friday, March 7, 8 o'clock a. m. Found her at home, calm and in her right mind, but extremely weak. At this time met Dr. W., from Mount Pleasant, Pa., another brother of my patient. We stopped all medicine, gave beef tea freely, milk without limit, small quantities of brandy and milk and egg-nog, carefully administered as the pulse and other circumstances would admit.

From this time my patient rallied without one unfavorable symptom, and when last I saw her, March 24, she was able to take her place at the table in good health.

What was the *cause* and *nature* of this aberration; there being neither quickened pulse nor heat of skin or head?

HOSPITAL REPORTS.

A CLINICAL LECTURE DELIVERED AT THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

BY WILLIAM GOODSELL, M. D.,

Professor of Gynecology in the University of Pennsylvania.

Reported by WILLIAM H. MORRISON, M. D.

Uterine Disease and Nervous Exhaustion—Vesico-Vaginal Fistula, Laceration of the Cervix and Perineum; Operations; Cure—Causation of Laceration of the Cervix and Perineum.

GENTLEMEN: The first patient who comes before us to-day is one for diagnosis. She states that she is thirty-two years of age, has been married thirteen years, and has had but one child, which is twelve years of age. She says that she has not used any means to prevent conception, nor has her husband. There must be some reason why she has been sterile for twelve years. She states that the labor was not very difficult, but I see from the notes of her case taken at the Dispensary that she has had a rupture of the perineum, which was operated on at another institution. This was done five years ago. At that time, she had a dragging sensation in the pelvis, and a bearing-down feeling as though something were coming out. She had backache and headache, and wakefulness. She also had leucorrhœa, but no trouble in micturition. She derived very little benefit from the operation, the symptoms remaining the same. The menses are intermittent; they come on, last a day and night, then disappear for the same length of time; again return and continue for a week. She does not lose an excessive amount of blood. Her face is haggard, and she tells me that for a number of years there has been more or less worry and difficulty in trying to make both ends meet. She dates the dragging sensations from her labor.

It is not easy to say whether these symptoms are due to genital lesions or to nerve-exhaustion. I honestly believe that the influence of the womb in producing the so-called uterine symptoms is very much overrated. When a woman is out of health and consequently with lax fibre, she will complain of pain in the back, and dragging sensations which have no connection with uterine trouble. Virgins, who have no laceration of the perineum, and in whom the parts are contracted, will complain of these pains, when their health is undermined by hard study or by any other kind of nerve strain. Men may have a pain in the back when worn out by mental or by physical exertion, but especially by the former.

If the symptoms in this woman were dependent on the laceration of the perineum, it is difficult to see why she was not and is not benefited by the operation; but this is the history of many of the operations performed on the uterine organs. Take, for instance, laceration of the cervix. You discover this lesion in a woman who complains of dragging pain, of headache, spineache, and backache, of irritable bladder, leucorrhœa, and wakefulness, and of cold hands and feet, and you will very likely attribute all these symptoms to the uterine lesion. If you assure her positively that by an operation you can cure her, you will often make a great blunder, for these symptoms do not always, do not in the majority of cases, depend upon the lesion, or on other uterine lesions. They are tokens of nerve-exhaustion, as well. This overrating of the womb, as a cause of disease, is, in my opinion, the great error of the day. On the other hand, a woman may have a laceration of the cervix, and yet, while she is suckling her child, she may not suffer from the lesion; but when menstruation returns, the presence of this injury invites too much blood to the womb and its annexes, and we have the symptoms of bearing down and the like, from irritation and overweight of these organs. The same thing happens from nerve-exhaustion. A woman suffering from this condition will have bad headaches and nape-aches. What is the meaning of these aches? They indicate disturbances in the circulation of the blood in the brain, too much or too little being present. So it is with the back-aches and spine-aches, which in a large number of cases are due to passive congestion of the spinal cord. All the pelvic organs, which are the exacting organs during woman's menstrual life, will receive too much blood because of a lack of coördinating power in the nervous system. The ovaries and womb become enlarged and painful, the womb sometimes measuring as much as three inches in virgins. It is not always easy to decide what rôle is played by the uterine lesions and what by the nerve-lesions; but the womb being see-able and touch-able, we make it the scape-goat. Let me repeat again, that the burning error of the day is the attributing to the womb symptoms which are due to nerve-exhaustion. Consequence is mistaken for causation.

I have not yet examined this woman, but my inference is, from the fact that the operation was of so little benefit, that there must have been something in addition to the ruptured perineum. In weak women a labor may produce sufficient shock to be followed by nerve-prostration. When I first saw this woman I was struck with her appearance; for although she is but thirty-two years old, she shows the lines and furrows of suffering, and that of a mental character.

Making a vaginal examination, I find one cause of the bearing-down feeling. The womb is retroverted and prolapsed. The perineum which has been formed is only a skin-perineum. Let me dwell upon this point for a minute. All beginners, in performing operations, are afraid of the knife, and they cut too little. In operating for lacerated perineum, I never denude less than one inch in width, oftener more. If too much be removed, the surfaces cannot be brought together. This perineum is a membranous one, and does not

slope up like the breast of a dam, as it ought to. It should be thick in front and gradually slope inwards. I do not say that in this instance the insufficient perineum is attributable to any fault in the operation. I have, even after great care in denuding a large surface, occasionally been vexed to find the perineum not as thick as I had wished and expected. Sometimes nature will make a membranous perineum. During labor, the perineal centre and muscles may be torn, while the skin from its elasticity may remain intact. Then we are obliged to operate precisely as in cases in which the perineum is completely torn. When the womb is so low as this, the ovaries are liable to be prolapsed, and on the left side I feel one which appears to have undergone cystic degeneration. I cannot feel the right ovary. The womb measures plus 3 inches, and there is a slight laceration of the cervix.

I am disposed to think that if we can relieve the local trouble, she will recover only in a measure from the nervous symptoms. Sometimes in cases of nerve-exhaustion, with local troubles as in this patient, although you put in a pessary which keeps the womb in a proper position, the woman will feel no better, unless, perhaps, she may be able to walk better, showing that there is a something behind the merely local trouble. This patient says that she cannot wear a pessary. The proper mode of treating a case of this kind in private practice would be by the use of large douches of very hot water—not a small injection, for this would do more harm than good. One or two gallons should be used. Most of the patients who come to the hospital are too poor to use these injections, because it requires an attendant, an expense which they cannot afford. The way in which these large injections do good is by constringing the capillaries of the part. The first effect of hot water is to invite blood to the part, but the secondary effect is to contract the vessels, and thereby lessen the amount of blood in the part. If the object is simply to cleanse the vagina, you should order a quart of water warm enough to be comfortable; but if you wish the therapeutic action, you should use one or two gallons as hot as can be borne, usually at a temperature of from 110° to 115°; sometimes a temperature of 120° can be borne, if the nozzle of the injection-tube be made of rubber.

If the patient cannot use the injections, the next best thing is to use anodynes in the vagina. I generally order the following:

R. Morphine sulph.	gr. ss.
Extracti belladonnæ,	gr. ij.
Olei theobromæ,	q. s.
M. Et ft. vag. suppository No. 1.	

Sig.—To be used at bed-time.

In this case, however, I shall use iodoform, ordering a vaginal suppository containing 5 grains, to be slipped into the vagina, after she goes to bed at night, and the application of a guard to prevent the escape of the melted suppository.

I shall also order my favorite mixture:

R. Ammonii chloridi,	
Ammonii bromidi,	āā ʒiv.
Infus. gentianæ comp.,	ʒvi. Solve.

Sig.—A dessert-spoonful before each meal.

If the ammonium chloride disagrees with the

stomach, the dose will be reduced. This is one of the best remedies which we have for glandular enlargements. To it I may add digitalis in full doses.

How shall we support the womb? In private practice, I should use an inflated ring pessary. This is expensive and very perishable. I have seen them wholly collapse in two weeks; and being made of soft rubber, they make a very offensive smell; and in addition there is a scientific objection which applies to all ring pessaries, and that is that they act not by elongating the vagina, but by widening it. A good plan in the present case would be to use oakum, placing a little pad in front of the cervix and one behind it, and then a pad in front of the cervix to retain the others in position. Oakum has two advantages; it contains a great deal of tar, and is therefore a disinfectant, and does not readily decompose, and being covered with tar, there is not much tendency to absorb moisture, and it therefore retains its elasticity. If cotton is employed, it should not be the absorbent variety, but ordinary raw cotton which contains a considerable amount of grease, and does not on that account take up the moisture.

Vesico-vaginal Fistula, Laceration of the Cervix and Perineum: Three Operations, All Successful.

This patient is one on whom I have performed three operations. The first was for vesico-vaginal fistula, which has been cured; the second was for lacerated cervix, which was also successful, and the third was for lacerated perineum, which, as you see, is restored. I think that I made a mistake in not sending her home after the second operation, in order that she might recuperate. She did not bear the operation very well; the stitches cut a great deal; but still perfect union has taken place. The tear of the perineum had gone through the sphincter, and the rectum and vagina were converted into one large opening. The operation was done two weeks ago. At bedtime, on the ninth day after the operation, a clyster, consisting of one ounce of glycerine and two ounces of sweet oil, was introduced into the rectum, and two Lady Webster and two compound cathartic pills were taken. The object of the glycerine was to dissolve the hard masses in the rectum. The bowels were moved without any trouble, there being no scybalous masses passed. In every case in which I have used this injection it has acted very satisfactorily.

The difficulty in this perineal operation, when the anus has been torn, is not in restoring the sphincter muscle, but in the liability to non-union above it, causing a recto-vaginal fistula. This is liable to occur if the stitches are left in too long. In a recent operation of this kind, I had a recto-vaginal fistula left after the rest of the wound had healed. At the end of two weeks, after the union was sufficiently strong, I introduced a rectal speculum, and made applications of nitric acid to the whole track of the fistula. Between these applications nitrate of silver was used—first the solid stick, then a strong solution, and in two weeks the fistula was closed.

Laceration of the Cervix and Perineum. Caustion.

This is the first time that I have seen this patient. She is 31 years of age, married, and has

four children, the youngest of which is two years old. She has pains in the head and in the stomach, and suffers from cold hands and feet, and has to pass her water frequently.

Let us see what can be elicited by a vaginal examination. The first thing I detect is that the perineum is torn down to the sphincter. The cervix also is torn, and on the right side. In one of her labors the head was probably in the right occipito-posterior position, but she says that instruments were never used in any of them.

Tears of the perineum will occur whether the physician uses the forceps or not, but in the majority of cases they come from the use of the forceps, or rather, from my point of view, from the abuse of the forceps. Let me give a piece of advice to you as young men. When the proper time comes, put on the forceps and boldly bring down the head secundum artem; but when that head begins to bulge the perineum, take off the forceps. I do not think any of you are competent to deliver the head over the perineum with forceps. The temptation is to turn the head out too quickly. If you take off the forceps, as I have suggested, you will rarely have a bad tear of the perineum; and if a tear occurs you will not get the blame of it. It is a very rare thing for me to end a labor with the forceps on. When the perineum begins to bulge, I support the handles to see whether the pains are strong enough to end the labor. If so, I remove the forceps.

As I have said, I think that the tear of the cervix was produced by the head coming down in the occipito-posterior position. Perhaps the occiput did not rotate anteriorly. This would be very apt to cause the tear of the perineum. Under such circumstances, the physician would be justified in keeping on the forceps, because he can by forcing flexion lift the head over the perineum, and, to a certain extent, prevent laceration. In such a case, you would be warranted in delivering with the forceps. But these cases are very rare. I have seen but one.

This is a case for operation, and perhaps next week I shall restore the cervix, and a week or two later operate on the ruptured perineum.

Let me now say a few more words in reference to the use of the forceps. There is such an abuse of this instrument that I sometimes think that Baudelocque was right when he said that the forceps had done more harm than good. It requires great skill and judgment to end a labor with forceps. A physician from inexperience, or being demoralized by a long and tedious labor, is liable to use undue violence and deliver the head too quickly or to make traction in the wrong direction. I have myself torn the perineum, and have seen many good physicians do the same. From this experience, I should recommend that unless there be an excellent reason for contrary action, the forceps be taken off when the head reaches the perineum. Occasionally one blade of the forceps will catch over an ear and you cannot get it off, but in the majority of cases they can be removed, and this is the proper thing to do.

Once in a while, a bad tear of the perineum will be produced in a breech case, because the physician forgets the curve of carus. He does not carry the body upwards as he should do, and the

chin catching on the perineum, tears it; but in nine out of every ten cases, a bad tear of the perineum is, in our experience, here due to the forceps.

A number of years ago I was called to assist a physician who had a large obstetric experience. He had become completely demoralized over a tedious labor. He had put the forceps on and had got through the worst of it when he gave out and had to send for assistance. I then took hold, and after bringing the head down to the perineum, handed the forceps to the physician to complete the labor, so as not to take the wind out of his sails. He at once turned the head out, and I felt sure that something must have given way. After the placenta was delivered, he went to wash his hands, and while he was doing so, I took the opportunity of examining, and found the perineum torn down into the rectum. I asked him to examine the parts. He put his finger in the vagina, and said: "Oh, yes! the placenta has been taken away; everything is right." I then called his attention to the rupture of the perineum, and a look of blank astonishment came over his face. Neither of us had a needle. So we borrowed a darning-needle and sewed up the parts with stout linen thread. The union was perfect. I have seen the same thing happen in other cases to which I had been called, and, in my younger days, I have done it myself.

Suppose you do meet with this accident, what is to be done? I say, first discover it. In many instances, even of complete tear, the lesion has not been detected until the patient has had her bowels moved. This is inexcusable carelessness, of which you must never be guilty. After every labor you should pass your finger into the rectum and the thumb into the vagina and gauge the depth of the perineum. If you are not sure, decently make an ocular examination of the parts. A tear is discovered, introduce stitches there and then, and in the majority of cases perfect union will result. It is not usually necessary to put the patient under ether, for the parts are benumbed by the excessive stretching to which they have been subjected. Pain is experienced only during the puncture of the skin; therefore, this should be done quickly. You should always be prepared for such an emergency, and always carry a perineal needle and a supply of silver wire. Shot are not necessary, as twisting answers every purpose. I can say one thing for your comfort, and that is, that a tear which looks very large will be reduced fully one-half when the parts have contracted to their normal condition.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Discussion on Inflammation of the Ear.

(See page 733.)

Dr. C. H. Burnett, in opening the discussion by request of the chair, said: It is very important to find out the real cause of pain and inflammation in the ear. Very often it is due simply to a closure of the Eustachian tube and not to inflammation in the tympanic cavity, or it may be due to an inflammation in the membrana flaccida, or

Shrapnell's membrane, in the upper part of the membrana tympani, the latter being unaffected. In the former instance the membrana tympani is drawn inward by the vacuum formed in the middle ear by the closure of the Eustachian tube, the ossicles are forced inward, pressure is exerted on the contents of the labyrinth, the filaments of the auditory nerve in the semi-circular canals are compressed, and reflex irritation of the cerebellum, with vertiginous symptoms, result.

Inflation will remove in many cases the pain in the ear and other symptoms, without the resort to leeches or paracentesis.

The surgeon should not be swift to incise the membrana tympani, especially simply to relieve pain in the ear. The membrane should be incised only when it bulges in consequence of fluid accumulations within the tympanic cavity. If an acute inflammation exists in the membrana flaccida, causing pain, this part of the membrana tympani may be incised with great advantage. Repeated incisions in the membrana tympani, especially in acute cases, for the relief of pain, are rarely, if ever, demanded. When suppuration and discharge have been fully established, cleansing by the use of absorbent cotton on the cotton-holder and the use of powdered boric acid, either pure or in combination with resorcin or chinoline salicylate—*i. e.*, the dry treatment—will be found more efficient than the use of the syringe or astringent drops.

Recurring again to acute cases of inflammation in the ear and earache in children, I would recommend a sudorific and anodyne treatment, with the administration of aconite in proper doses, as preferable to depletion or scarification about the ear. The child should be, of course, carefully housed during the acute and painful stages of the disease. The surgeon should bear in mind that when called to see a child or any one affected with an acute inflammation in the ear, that domestic remedies may have been used, and have aggravated and masked the disease. Very often the ear-pain may be relieved by simply washing from the auditory canal various irritant salves, and a host of pungent domestic remedies, which would be enough to make a well ear ache.

Dry heat is the best remedy in the early stages of many cases of otitis, and its application will often bring about a resolution of acute congestion in children or adults. In fact, at the outset mild remedies or nothing should be applied to an ear acutely inflamed, whether the seat of the disease be in the external canal, the drum-membrane, or the drum-cavity.

If a furuncle be diagnosed in the auditory canal, it should be incised at once. This usually obviates the necessity of all forms of poulticing, and prevents the tendency to the formation of other boils by cutting short the congestion in the skin of the canal.

Dr. Lawrence Turnbull: "I cannot but express my pleasure at the way the subject has been brought before us, namely, the hygienic importance of the subject. Most of you are aware of the publication of my little work on this subject, and of the proposition which will be found in it worded as follows: 'Of all the injurious influences combined, none, however, are so hurtful to the integrity of the human ear as cold.'

"All the main propositions which the gentleman has put forth in his essay I approve of; but I would make this reservation, that it is always a difficult matter to determine whether we have a true catarrhal inflammation of the middle ear to treat, or a purulent one, so frequently do the symptoms run together and become mixed. In the ordinary or simple form of catarrhal inflammation of the middle ear, you will have a rapid development of acute inflammation, with pain, heat, swelling, and redness, and in from twenty-four to forty-eight hours a sudden giving way of the drum-membrane, followed by a discharge of mucus not mixed with fully-developed pus, and the child almost always soon recovers from it.

"In the second form you have an acute inflammation which involves the deep-seated tissues, blood-vessels, etc., and if not checked promptly will ultimately destroy the membrana tympani, and may involve the bone or brain itself, with profuse discharge, for days, weeks, or even months, of pus, blood, and broken-down tissue and bone. Now, I consider that the most important treatment is to relieve pain, and I find in little children with their distressing cries which appeal to every one's heart, that nothing is so good in the early stage as to apply a bag of hot salt or sand, and covering it with a piece of flannel, place the patient's ear over it, or applying by binding it to the ear, as the little one is very restless and tosses about. If there is no hope of the resolution of the inflammation, then moist heat should be applied by means of a large hop poultice covered with oil silk, and renewed when it becomes cool. After using all the ordinary means to prevent and control inflammation, and none are of so much importance as those which afford relief to pain and quiet the excited nervous system, I administer to children the syrup of chloral with bromide of potassium, or in place of the chloral the camphorated tincture of opium; while to the adult I find nothing so prompt to relieve the agonizing pain as morphia sulphat. and atropia sulphat., the first in doses of $\frac{1}{12}$ to $\frac{1}{8}$ of a grain, and the latter in $\frac{1}{15}$ of a grain to $\frac{1}{10}$, combined with a minute portion of the sulphate of iodine in solution, and administered hypodermically. Some good authorities, like Politzer, prefer to give the morphia in $\frac{1}{3}$ of a grain at night and repeated; but in many instances we have found it rejected by the stomach. If we have not been successful in checking the disease, and we find that the inflammation is followed by perforation, we have then purulent otorrhœa, which, if not checked, may involve the posterior membrane, and at times the mastoid process and cells, and if there is great dizziness present, the labyrinth is apt to be involved. A case of the first kind, abscess, in the posterior fold or Shrapnell's membrane, of the drum-membrane, I opened an abscess this day from a neglected catarrhal inflammation, with prompt relief to the tumulus. Again, we have a sub-acute inflammation of the middle ear, but no perforation or severe inflammation of the posterior surface of the drum-membrane: an effusion of blood or serum takes place, which, owing to the transparency of the membrane, can be seen as a yellow reflex with a dark hair-like line. This dropsy is to be treated by the use of the inflator of Politzer, the nozzle being carefully introduced

into the nose, a little water in the mouth, and with head carried forward and to one side, so as to facilitate the passage of the fluid contents into the pharynx; the patient swallows, and the air is propelled into the middle ear, and, if successful, the bubbles of fluid can be seen behind the surface of the drum-membrane.

"Some physicians resort to paracentesis, even when the Eustachian tube can be opened by the air-bag. Now, I am one of those who consider this operation a very simple one, and any physician can perform it if there is a good, large, not swollen meatus, and a speculum, good light, and forehead mirror; yet my experience is against its frequent performance in inflammation of the middle ear, as it often destroys the membrane entirely, or leaves a persistent and troublesome otorrhœa or chronic suppuration of the middle ear in scrofulous, tuberculous, or nervous patients.

"I have also noticed bad results follow the use of local depletion in this same class of patients by leeches or cups.

"But I approve of and perform paracentesis, and recommend it in healthy children and adults, when from the appearance of the membrana tympani there are sure indications that perforation is about to occur, when there is a yellowish green discoloration of the membrane, with bulging forwards, with a livid red swelling and intense pain radiating all over the side of the head and face."

Dr. G. G. Davis: "I am surprised that in this discussion the use of hot water has not been advocated more strongly. A quart of water allowed to run into the ear from a nasal douche will usually be sufficient. It is a plan recommended by Roosa in his treatise on diseases of the ear, and is one that I have tried with satisfaction. It is usually all that will be required for most of the milder cases and many of the severer ones. I think it should, usually, be tried before resorting to the severer procedures of leeching and puncture of the membrane."

Dr. Heyl: "The reference which was made by Dr. Burnett, in the opening remarks, to a class of middle-ear affections which, though in many features suggesting acute catarrh of the tympanic cavity, are really pneumatic disturbances, as illustrated by a case which I have now under treatment. Some two weeks since I was sent for by a gentleman in the upper part of the city, with the request to bring instruments for cleansing his ear, as he was sensible of great pressure upon the drum-head which, perhaps, might be due to wax. He gave me the following history: Several days previous to my visit, he had noticed on retiring to bed a sticking sensation in the ear; during the night this increased to a violent pain. In the morning he began to hawk and spit mucus or mucus-pus mixed with blood. After two or three days, on attempting to rise from bed and walk, he was obliged to vomit freely; this was apparently due to the effort of walking or maintaining the upright position. About this time I saw him. I found the pain much lessened, but a great sensation of pressure in the ear; hearing dull, noticeably so to the patient, who says that it has always been acute. Watch, $\frac{3}{4}$ ". Examination of the drum showed some injection along the malleus handle and membrana flaccida. Membrana tympani lus-

treless. Relief experienced from cautious inflation with the Politzer method. Under appropriate treatment the patient is progressing toward recovery. Now, what was the diagnosis of this case? At first I was inclined to think it was a case of catarrhal tympanitis, and rather expected to see perforation take place with the formation of pus. But on observing the progress of the case, I came to the conclusion that the real difficulty was about the pharyngeal orifice of the tube, which so affected the muscular arrangements of the ossicles as to interfere with the normal pneumatic condition of the middle ear, which I believe depends in a measure on the proper action of these muscles—at least those connected with the palate and Eustachian tube. I may simply refer to two other symptoms which this case presented.

"1. A difficulty of maintaining equilibrium; a sensation as if walking on a rocking boat, and the disposition to vomit which accompanied it. This, doubtless, was referable to the semi-circular canals, but a curious feature was that it was very much aggravated by the vibrations of the tuning fork placed on the mastoid. This effect of the tuning fork probably often occurs in middle-ear troubles, although I do not remember to have seen it so marked as in this case. It suggests the thought of the susceptibility of the nervous connections of the semi-circular canals to sound-waves.

"2. There were slight psychical symptoms in this case, such as great indisposition for work, or conversing with any one; a sense of uncertainty about the ability to perform work; a sense of mental instability. Careful observation will probably show that a very close connection exists between abnormal mental symptoms and abnormal intra-aural conditions."

Dr. Risley: "I feel indebted to the lecturer for calling forth a discussion on this very practical theme. Any scheme looking toward the hardening of one's self against cold-taking, should be very carefully scrutinized before its adoption. Regarding the operation for paracentesis of the drum-head, I think its importance has not been set forth with sufficient emphasis in the paper of the evening. I agree fully with Dr. Burnett in the views he has expressed regarding the rare necessity for its repetition.

"In the treatment of acute catarrh of the middle ear, strict regard should be paid to the stage of the disease. At the beginning of the acute inflammation, the general treatment is of great value, and he regarded tinct. of aconite, syr. of ipecac, spts. ætheris nit., etc., quite as important here as though the inflammation had attacked the mucous membrane elsewhere, *e. g.*, the bronchi. The aconite is an especially valuable adjunct to the local treatment employed.

"To guard the patient from all exposure is quite as important for the successful treatment of a severe acute catarrh, involving the Eustachian tube and tympanum, as in the treatment of a bronchitis or pneumonia; confinement to bed between woolen blankets should in bad cases be rigidly insisted upon. The local treatment is of great value, but must be directed with due regard for the stage of inflammation and its severity.

"In mild cases, freedom from exposure and an aconite mixture, with a little ipecac, will be quite sufficient, if the nasal passages and pharynx are

kept free. If the attack is more severe, showing marked swelling of the mucous membrane of the pharynx and nose, and is attended with pain, the efforts for relief from the intense suffering are first in demand.

"One of the simplest methods for relieving the pain—one always at hand, and in his experience one of the most effective—is the application of hot water applied to the external meatus. It must, however, be *hot*. It need not be applied forcibly or in large quantities. To pour the water in from an ordinary *pipette*, the head being held well over to the opposite side, is usually quite sufficient. The temperature of the water must be kept up by frequent repetition of the process, until the pain is relieved, which very soon results if the plan is to be successful. It, however, in some instances, seemed to aggravate the suffering of the patient. If relief does not follow the thorough application of the hot water, the leeches are applied in front of the tragus, as recommended by Dr. Burnett. If the inflammatory process is not arrested, there soon follows, especially in badly nourished or feeble persons, a stopping of the middle ear with mucus and exudates, with great aggravation of the patient's suffering. It is at this stage of the disease that paracentesis is usually beneficial, and very frequently urgently demanded.

"The appearances of the drum-head under these circumstances, the results of paracentesis and the usual features of this disease, I will illustrate in the case of a little girl nine years old—at the present time under treatment, but convalescing from a violent attack of acute catarrh of the middle ear, Eustachian tube, pharynx, and nasal passages. She was at the time under treatment for a subacute attack, which had caused tinnitus and some hardness of hearing. She had the day and evening before the attack gone through the excitement, fatigue, and possibly exposure, incident to a birthday party. In the night severe pain came on in the right ear, and the nose was stopped by an acute coryza. Sweet oil and laudanum were poured into the meatus, but without relief. The following day was stormy, so that she was not brought for advice until the third day, and was then found still suffering so greatly that she was crying with pain. The meatus was very tender, so that traction upon the auricle aggravated the pain. The membrane of the tympanum was a brownish red or copper color, and the superior posterior quadrant was bulging outward and downward; at the center of this almost bagging part of the membrane was a yellowish red point. I did not hesitate to perforate the drum-head at this point, and a moment later with the air-bag was able to force through the incision a few drops of a nearly chocolate-colored serum. The pain was relieved immediately. The meatus was greatly cleansed, a wick of borated cotton, saturated with a solution of atropia sulph., placed in contact with the drum-head, and allowed to remain, the pharynx and nasal passages washed with a weak solution of sulphate of zinc, and the child sent home, with instructions that she be placed in bed and the aconite mixture given if she should be feverish in the evening.

"The following day she was seen at her home; there had been no return of the pain; in forty-eight hours the wound in the tympanum was

closed; and at the end of the week she was quite recovered, even of the subacute catarrh, for which she had been under treatment before the violent onset of the acute inflammation.

"A thorough and careful attention to the coryza, which very usually precedes these inflammations of the middle ear, would prevent their occurrence in most cases."

Dr. F. J. Buck: "I have often relieved severe ear-ache almost instantly by placing some loose cotton in the bowl of a pipe; then moisten the cotton with sulphuric ether, and blow the vapor into the ear through the pipe-stem."

Dr. Wm. T. Taylor: "To relieve the ear-ache of children, I have used chloroform in a similar manner to that described by Dr. Buck."

Dr. Wm. S. Little: "It would be difficult to lay down any rule that would apply to all cases in the process of hardening the system so as to prevent catching cold. The sensibility of the skin varies so in individual cases, the effect of heat and cold, the action of irritants upon the

skin, producing different results in individual cases; the Turkish and Russian bath not being allowable in many cases.

"The hardening of the system by exposure has been advocated by non-medical men who have been close students of nature, but the *genus homo* does not thrive as other *genera* do in undergoing the process.

"The treatment of ear affection following catching cold is often rendered more easy, in addition to the methods already discussed by the author of the paper, and gentlemen following in the discussion, by inhaling medicated vapors; compound tincture of benzoin in boiling water being a very agreeable and soothing medication.

"The inhalation of burnt brown sugar is a very homely but very valuable method, several cases of severe catarrhal conditions of the throat and ear being cured by persons who had resorted to various plans of medication prior to their working in the refining room of a sugar factory."

EDITORIAL DEPARTMENT.

PERISCOPE.

The Treatment of Hay Fever.

Dr. Morell Mackenzie publishes a lecture on "Hay Fever" in the *Brit. Med. Jour.*, May 19, 1884, from which we extract the following:

The treatment of hay fever is by no means satisfactory, and in no disease is the old adage, that "prevention is better than cure," more truly applicable than in the case of this complaint. If the poison be continually introduced into the system, the antidote, if one exists, can have but little chance of effecting a cure. The first measure, therefore, must be to remove the patient from a district in which there is much flowering grass. A sea-voyage is probably the most perfectly satisfactory step that can be taken. Patients who are unable to go to sea should endeavor to reside on the coast, where they will generally be free from their troublesome complaint, except when land-breezes blow. Dwellers in towns should avoid the country, and those who reside in the country should make a temporary stay in the centre of a large town. It often happens, however, that such a change of abode is not practicable; and, under such circumstances, if the complaint be very severe, the patient should, if possible, remain indoors during the whole of the hay season. Many persons, of course, cannot keep in the house during the month or six weeks of the hay-fever period; and those who can, are apt to find such detention not only exceedingly irksome, but very injurious to the general health. If, therefore, a patient be obliged to go out of doors, he should plug his nostrils with cotton-wool or wadding, by means of one of Gottstein's screws, and should defend his eyes by wearing spectacles with large frames, accurately adapted to the circumference of the orbits. Plugging the lachrymal ducts with

small glass rods has also been recommended,* and Thorowgood speaks † favorably of a little apparatus containing a few drops of a camphorated or carbolized solution, which can be comfortably worn in the nostrils. Instead of *plugging* the nose, it has been advised‡ to close it by compression with a little metal clip. As rapid motion in the open air almost always aggravates the complaint, it may be advantageous to wear a veil over the face whilst driving. One made of "three ply" of fine silk gauze has been found very useful.¶ It is recommended that it should be made in the form of a bag open at both ends, one end fitting round the hat, whilst the other has attached to it a heavy wire ring about ten inches in diameter, which lies on the shoulders and keeps the veil off the face. Those who do not mind being occasionally mistaken for the "veiled prophet of Khorasan," will no doubt adopt this plan. Protected in this way, many people predisposed to hay fever escape altogether, whilst others contract the affection in a very mild form.

As the disease most commonly occurs in persons of nervous temperament, nerve-tonics and other constitutional remedies have been used for the purpose of warding off hay-fever, or controlling the violence of its attacks. Amongst these, quinine, arsenic, opium, and belladonna have been employed; but I have found valerianate of zinc, in combination with assafetida, more valuable than any other drug. I usually give the remedy in the form of pills containing one grain of valerianate of zinc, and two grains of the compound assafetida pill, doubling the dose at the end of ten days or a fortnight. I direct my patients to be-

* Hannay: *British Medical Journal*, 1881, vol. ii., p. 872.

† *Lancet*, 1881, vol. ii., p. 82.

¶ *British Medical Journal*, 1883, June 30.

gin taking these pills as the hay-season approaches; and, under the use of this remedy, many persons who formerly suffered most severely from hay-fever have ceased to be troubled with it.

When the disease is established, tincture of opium is of great benefit in controlling hay-asthma, reducing the secretion, diminishing the sneezing, and at the same time bracing up the nervous system. It should be given in small doses of five or seven drops twice daily, and a saline purgative should be taken on alternate mornings. Belladonna has been recommended, but I have had no experience of its use in this complaint.

I trust very little to local measures in the treatment of hay-fever; but when there is profuse secretion, with an excessive tendency to sneeze, the inhalation of strong ammonia salts often gives great relief. I have not found injections of quinine, as recommended by Helmholtz, at all useful. Though in a few cases benefit was derived, in most instances no effect was produced, whilst some patients were actually made worse. The good effect is probably to be explained by the injection mechanically washing away the *corpus delicti* rather than by any parasiticide action. The same remark may apply to the case in which Binz* states that a solution of one part of salicylic acid to one thousand of water, thrown into the nares, cut short the disease. The vapor benzoini of the Throat Hospital Pharmacopœia has occasionally produced a soothing effect; and I have also seen good results from insufflations into the nose of a powder consisting of one-sixteenth of a grain of morphia and one grain of bismuth. This should be applied several times a day. Ferrier's snuff may be substituted for the above formula, but it should be applied by insufflation. It is also said† that great advantage has been derived from the snuffing of pure salicylic acid, ten or fifteen grains being used in this manner in the course of the day. As, however, this powder is very "strong," I am inclined to believe that most persons would find the remedy worse than the disease.

In a few cases I have known some benefit result from the use of medicated bougies, such as the bismuth and acetate of lead Buginaria of the Throat Hospital Pharmacopœia; but, like quinine-spray, they occasionally aggravate the mischief they are meant to cure.

The upper lip and the margins of the nostrils should be smeared over with benzoated zinc-ointment two or three times a day, when those parts are inflamed, or aconite liniment may be used in the same way.‡

For the relief of the irritation of the eyes, frequent bathing with very cold water is sometimes useful, though Roberts|| appears to have found more benefit from warm and slightly salt water. Sulphate of copper (two grains to one ounce) or sulphate of zinc (two grains to one ounce) may sometimes do good, but I have found a lotion containing two grains of acetate of lead with two drops of dilute acetic acid in an ounce of water, the most soothing application. Sedative collyria

occasionally allay the irritation: for this purpose a small quantity of a solution of acetate of morphia (one to three grains to an ounce) may be dropped into the eyes when they begin to itch.

Asthmatic patients are often relieved by inhaling the fumes of nitrated blotting-paper, the good effect of which is further increased by steeping the paper in a solution of stramonium, datura tatula, belladonna, or lobelia. A patent American remedy, consisting of nitrate of potash and powdered herbs, of which stramonium or datura tatula is probably the most important, is sold under the name of "Himrod's Cure,"* and when this powder is lighted and the fumes inhaled, they sometimes quickly relieve the spasm.

In hay-fever, the food should be nutritious and easily digestible. Owing to the depression which the complaint causes, stimulants are sometimes necessary; but they should, if possible, be avoided, or only taken in small quantities. Light claret, hock, and whisky diluted with water, are the least injurious. Tea and coffee have a special value in the asthmatic form of the disease, both in relieving the spasm and counteracting the exhaustion which follows it. Thorowgood† recommends citrate of caffeine for the same purpose, especially in cases where the heart is weak; he gives it in doses of two to three grains, dissolved in water or in warm coffee.

A New Sponge.

In the *Lancet*, May 3, 1884, Dr. Sampson Gamgee says:

"To Sir Spencer Wells I am indebted for the suggestion which led me to experiment with a variety of materials, with a view to preparing a sponge combining absorbing power and elasticity, and cheap enough to be burnt after use, so as to render sponge infection impossible.

"My first idea was to make a combination of pitch-pine shavings and absorbent cotton, within absorbent gauze. The resulting ball answered the purpose fairly well, but it was not soft enough. It would be tedious and profitless to recount the experiments made with almost every variety of vegetable and animal fibre, in combination with absorbent gauze and cotton. Willow shavings and Manilla fibre had brought us to what appeared very near perfection, when I accidentally found that a ball of curled cocoanut fibre, enclosed in absorbent gauze, sinks in water. That established, we made other balls with absorbent cotton in the centre of the cocoa-nut, absorbent cotton round it, and then the gauze envelope; the idea being to take up the fluid rapidly and transmit it, through the springy cocoa-nut fibre, to the absorbent cot-

*The original formula of this remedy has recently been published in one of the pharmaceutical journals. It is said to consist of stramonium, lobelia inflata, black tea, and nitre, in equal parts. If a little powdered aniseed or fennel be added to this preparation, it certainly produces a compound which in appearance and effect is very similar to that of Himrod's remedy. Careful microscopic examination, made at my request by those familiar with vegetable structures, has, however, failed to detect any tea-leaf in Himrod's preparation, though, of course, it is readily seen when the formula now given has been used. On the other hand, bearing in mind the fact mentioned in the text, that the drinking of tea often gives great relief to asthmatics, it is not at all improbable that the herb may have some effect, if burnt and inhaled.

||New York Med. Gaz., October 8, 1880.

ton centre. By experiment, I found that a ball so made takes up most readily from sixteen to eighteen times its own weight of blood or water, which, when squeezed out, still leaves the ball elastic and absorbent, readily filling, and swelling out again, when dipped in liquid and squeezed, a number of times in succession.

"The results so far obtained were approved by Sir Spencer Wells, Sir William Mac Cormac, Dr. Richardson, F. R. S., Dr. Thomas Keith, Dr. James Sawyer, Dr. Robert Saundby, Mr. Joseph Bell, Mr. Christopher Heath, Mr. Pearce Gould, Mr. Edmund Owen, and Mr. Walter Whitehead, whom I only mention to acknowledge the very valuable assistance and friendly encouragement they have been good enough to render me.

"Once I had secured a good combination of fibres, it became a question how to render them perfectly and *permanently* antiseptic. This fresh start led on to another series of trials, of which it is only useful for present purposes to recount the end. Every endeavor having failed, it suddenly struck me that within the absorbent cotton nucleus of the sponge might be enclosed a very thin ball or capsule, containing the antiseptic, of any kind, and, within certain limits, in any quantity desired; the antiseptic to be set free by cracking the capsule with a squeeze, just before using the sponge. The idea proves perfectly practicable, and Messrs. Burroughs, Wellcome & Co., the manufacturing chemists, have undertaken to carry it out. Some little time must elapse before all the details can be perfected; but sufficient evidence has so far been obtained to warrant the belief that the principle of my sponge may be adapted to the fulfilment of many requirements, as an absorbent and antiseptic sponge, pad, or dressing, in civil or military surgery, in medical and in obstetric practice."

Injection of Solution of Corrosive Sublimate in Prostatic Retention of Urine.

In the *Brit. Med. Jour.*, May 17, 1884, Dr. Wm. Robertson writes: "Having lately read certain articles, part of which were taken up in discussing the merits of certain agents as injections for the bladder, I have been induced to relate shortly my experience in a case of retention of urine from enlarged prostate, with catarrh of the bladder, treated with corrosive sublimate injections, of strength 1 in 1,000. The patient, J. A., aged 71, married, was under treatment for a similar attack fourteen months ago, when suprapubic tapping was required for relief; and the length of time during which the attack lasted was six weeks. The present attack was ushered in with rigors, frequent desire to micturate, restlessness, constipation, and various other feverish symptoms. By the rectum was found a prostate about the size of an orange, tender and hot to the touch. With a large prostatic silver catheter, easy access was gained to the bladder this time, and eight or nine ounces of decomposing smoky urine were drawn off. By means of the same catheter I injected three ounces of the sublimate-solution warm, and allowed it to remain in the viscus three or four minutes. The same night the patient passed comfortably, with a much modified desire to micturate. The urine drawn off next morn-

ing was clearer, but yet cloudy, with less odor. During the day he could retain his urine up to the evening, when the urine drawn off was almost free from decomposition, and only cloudy towards the end of the stream. The night following this was one of comfort. A bungling use of the catheter next morning set up anew the former symptoms to a certain extent, with smoky urine and frequent desire to micturate. In twenty-four hours this had subsided, with a return of the urine to its normal (as far as this patient is concerned) state. The patient has now been one week under supervision, with injections night and morning, and can retain, with ease, his urine during the interval of catheterism. The propulsive power of the bladder is now considerable, and handling of the prostate is borne with much less distress. Defecation causes little or no pain. The urine is in quantity 50 ounces, of specific gravity 1012, acid and albuminous. Its color is amber. This is but one case; nor can the local use of the sublimate carry much weight until more extensive trial has been given it; but after having in similar cases used other ingredients for such injections, my experience does not furnish such a favorable result as I have had here; and in a patient who, from a consideration of his age alone, and also the state of his urine, requires the most cautious handling.

Determination of Albumen in Urine.

In the *Brit. Med. Jour.*, May 3, 1884, Dr. Oliver describes a ready method for the quantitative determination of albumen in urine. The proceeding consisted in comparing the opacity produced by a test-paper in a definite measure of the albuminous urine, with a standard of opacity which represented a known per cent. of albumen; and in adding water, when it exceeded the standard, until the two were seen to be exactly equal. The standard opacity (representing 0.1 per cent. of pure serum-albumen) was preserved in a permanent form by precipitating chemically pure alum by means of ammonia, the opaque fluid being sealed up for use in a short flat tube. The estimations were made in a flat graduated test-tube of a determined diameter, three-eighths of an inch. A definite quantity of the urine (20 or 40 minims, according as the urine was strongly or only moderately albuminous) was poured in, and the albumen was precipitated by either a ferrocyanic or a mercuric test-paper. The opacity almost at once produced was compared with that of the standard by placing immediately behind the tubes printed lines; when it over-stepped it, the urine must be diluted to the required degree. The number of times the volume of the urine had been increased by dilution represented so many decimals per cent. of albumen: for example, 20 minims of urine requiring to be diluted to 180 minims contained .9 per cent. Dr. Oliver showed, on taking the twenty-four hours' urine, how readily by this method the total amount of albumen daily discharged could be expressed in grains; it was only necessary to multiply the percentage by 4.36 (or roughly $4\frac{1}{2}$), and the number of ounces of urine: for example, .6 per cent. $\times 4.36 = 2.6$ gr. to the ounce, $\times 50$ oz. = 130 grs., total loss of albumen in twenty-four hours.

In this way, he believed that accurate data could be provided without loss of time for comparing the effects of treatment on the amount of albumen eliminated: and he suggested that quantitative analysis of albumen might become useful in diagnosing the forms of renal disease.

Tubercular Disease of the Thumb.

Before the Irish Academy of Medicine (March 28, 1884), Dr. Bennett showed a specimen of tubercular disease of the thumb, affecting half the ungual phalanx of the thumb of an old woman which he removed last summer. There was an ulcer beneath the thumb-nail. She had no glandular disease elsewhere, or trace of trouble in the axilla or any part of the arm. The ulcer had lasted for five or six years. The best attempt at diagnosis he could make was that it was the ulcer of cicatrices of Hawkins and Marjolin. He believed that it originated with some form of suppuration, and that it then progressed and finally resisted all treatment. It was warty, excavated, and extremely sensitive at the edges, and when a probe was passed, it could be felt that the bone was exposed, though not naked. There was no rough or carious bone. Other treatment having failed, and the pain being great, he amputated the extremity of the thumb, and the case had since done well.

Dr. Purser said the reason why the specimen was called tubercular ulcer of the thumb was for want of a better name. In the present specimen, he had not looked for a micro-organism, but the characters of the growth, as discovered by an ordinary examination, were those of tubercle with certain differences. In the present case, some of the small cells were epithelioid, and others lymphoid; but there was no evidence of caseation, and that was the point in which the case differed from ordinary tubercle; but the growths themselves had quite the appearance of recent tubercles.

Dr. Bennett said that, although he had not at first recognized the character of the ulcer, he concluded that amputation was the best course. This, however, was the first example of the disease that he had seen. Tubercular and scrofulous diseases affected the bones, both of old and young, and were liable to be mistaken for malignant diseases; but a superficial tuberculosis existing on a surface for five or six years, and causing absorption of the bone by its pressure, was quite new to him.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT MEDICAL LITERATURE.

—The Alumni Association of the Chicago Medical College have published in pamphlet form the proceedings of their eighteenth annual meeting. It contains a necrological report, the address of the president, and other matters of interest.

—The New York State Board of Health have published a report on a remarkable outbreak of typhoid fever at Port Jervis, clearly due to in-

fecting milk. It is written by Dr. F. C. Curtis, and is worthy the attention of all sanitarians.

—Two novels are announced by two distinguished medical men, one by Dr. William A. Hammond, and one by Dr. S. Weir Mitchell. Both of these gentlemen have extensive practices in the specialty of nervous diseases, and it is a matter of astonishment how they find time to indulge in the vein of romance writing. Assuredly, however, they have but to draw on their observation for facts more wonderful than any dream of fiction. We may expect from such men a psychological analysis more subtle than that of ordinary mortals.

—Those who like science treated in verse and a discussion of universal relations, will find such in a privately printed pamphlet by Judge Thompson, of Wheeling, W. Va.

—In a recent reprint, Dr. Samuel Theobald, of Baltimore, discusses at length some modern theories regarding the pathogeny of sympathetic ophthalmia, viewed from a macroscopic standpoint.

—In a little book called "What and Why," the advantages of the bicycle and kindred vehicles are set forth. It may be had from Mr. A. A. Pope, 597 Washington street, Boston.

—We have before us a little book by Dr. John B. Hamilton, Surgeon General U. S. Marine Hospital Service, entitled *Lessons on Longevity, Paragraphs on Home Hygiene, and the Art of Prolonging Life*. He treats in popular style of food, cooking, sleeping-rooms, plumbing, funerals, and other matters of that sort. If what he says is not new, it is at least useful. Published by W. H. Morrison, Washington, D. C.

—The President's Address of the Texas State Medical Association, by Dr. A. P. Brown, discusses evolution, the history of medicine, and other subjects, in a pleasant manner.

—An appreciative memoir of Dr. John Forsyth Meigs, by Dr. William Pepper, will be welcome to the many friends of that late distinguished physician. It is a reprint from the Proceedings of the American Philosophical Society.

—Dr. Moses Gunn, of Chicago, in a recent reprint, discusses in an interesting manner the philosophy of manipulation in the reduction of hip and shoulder dislocations.

—Ophthalmologists will be interested to read some clinical observations on the use of jequirity in trachoma, by Dr. H. Knapp. His conclusions are that it is a quick, but not a safe remedy, and that at present its use ought to be restricted to cases of old and intractable pannus.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,

JOSEPH F. EDWARDS, M. D.,

} EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance :—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - - -	7.00

For advertising terms address the office.
Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,

115 South Seventh Street,

PHILADELPHIA, PA.

AN OBSTETRIC CASE

(Price, \$15.00),

OR

AN ELECTRIC BATTERY

(Price, \$25.00),

AS PREMIUMS.

Any subscriber to the REPORTER who will send us before the 1st of July the names of three new subscribers with their yearly subscriptions (\$15) or five new subscribers with \$25.00, will receive, for the three, an Obstetric Case complete, and for the five, an Electric Medical Battery complete. They are new, of the best make, and of guaranteed excellence. The new subscribers will receive the REPORTER free from the date of the remittance until July 1st next.

Address

DR. D. G. BRINTON,

115 South Seventh Street,

PHILADELPHIA, PA.

AGAIN AN OLD "TRUTH" PROVEN WRONG.

It has been the general opinion amongst physicians, that most cases of death from tuberculosis happen about the twentieth year. In some not yet so very old text-books we find even the statement, that when an individual, whose parents have died of tubercular consumption, had passed his twenty-first year, he was past the danger of dying of the same disease, and in persons, who present the phthisical habitus, and in whom the hereditary influence is dreaded, the age from 19 to 21 is considered the most risky period.

The Imperial Board of Health of Prussia, an institution whose President is Dr. Koch, and whose observations and investigations have already been in more than one instance of inestimable value to our profession, has recently published a treatise by Dr. Würzburg (*Allg. Med. Centr. Zeit.*, 31, 1884,) on "The influence of age and sex on the mortality due to tubercular phthisis." The statistical tables referring to Prussia (perhaps the most reliable in the world) prove that during the five years, 1875-1879, of every 10,000 persons of all ages living in Prussia the following percentage of deaths due to tubercular phthisis was recorded :

	Percentage.
Under 1 year	23.45
From 1 to 2 years	20.41
" 2 to 3 "	12.51
" 3 to 4 "	6.83
" 5 to 10 "	4.66
" 10 to 15 "	5.86
" 15 to 20 "	18.37
" 20 to 25 "	30.24
" 25 to 30 "	36.73
" 30 to 40 "	41.12
" 40 to 50 "	48.42
" 50 to 60 "	67.94
" 60 to 70 "	93.18
" 70 to 80 "	61.72
Above 80 years	25.80

These statistics prove that after a larger percentage of the first childhood the minimum of death-rate is met with from 5 to 10 years, and thence up to the period of from 60 to 70 years a continuous increase is noted. These statements apply not only to the state of Prussia as a whole, but also to every city and borough ; and it is as-

tonishing to observe the regularity which the death-rate evinced in every province, the death-rate being all over the same, often to within one-twentieth of one per cent.

The same condition has been noted in Sweden and in the United States, with the only difference that in these countries the death-rate increases even beyond the seventieth year, so that no diminution whatever takes place after the first increase happening at the tenth year.

England, however, makes a remarkable exception. There the highest death-rate falls between 20 and 30 years, while between 50 and 70 the least number of people die of consumption.

Concerning sex in Prussia and Sweden, the male sex suffers decidedly more from the malady, while in England and the United States the female sex has a slightly higher percentage in the death-rate. In countries in which the male sex denotes a greater mortality, the latter increases with advanced age, while in those in which the female sex predominates in the death-rate, the greatest number of victims is recorded during the period of development, and continues thus up to the 50th year, whence the men also evince a higher mortality.

If there is any difference in the death-rate between city and country, it is that up to the 50th year the mortality is greater in cities, while after that age more persons seem to die of consumption in the country than in the city. But the difference in percentage is very small.

EXPERIMENTAL RESEARCHES ON CORTICAL ATROPHY.

For the purposes of determining the effect of atrophy of the gray cortical substance of the cerebrum, Dr. V. Monakow (*Neural. Centrbl.*, 12, '84,) has made a number of experiments. After destruction of the part of the posterior internal capsule of a recently born rabbit, containing probably the fibres of the occipital lobe, the grown-up animal evinces besides a defect in the ganglionic cells of the corpora geniculata externa, and in the middle white substance and in the gray matter of the anterior corpora quadrigemina, a diminution

of the whole occipital lobe. The white substance showed atrophy in a high degree, but the cortical substance was also greatly diminished in quantity. The third layer of the cortex, with the larger ganglionic cells, was mostly injured, and the fifth of the bridge followed the first in degree, while the others did not indicate any decided alterations. Division of the internal capsule of a recently born cat caused a remarkable inhibition of the development of the motor tracts, and atrophy of the motor area in the ascending parietal convolutions of the left side. Here also, especially the great cells of Betz of the third layer were atrophied, otherwise only the nerve-fibres of the fifth layer were slightly degenerated.

Whether the destruction of the pyramidal tract or of the distribution of the fibres of the corpora quadrigemina, or of both, produced the atrophic conditions, has not been determined by these experiments. Still, they teach us, in all lesions of the brain, by a careful examination to determine the original morbid process, to decide what morbid alterations might be secondary. They also explain certain forms of want of development, as they are met with in idiotic persons, and in such where a disease of the brain in early childhood later leads to want of development of certain parts of the organism. It may be possible, in this manner, to demonstrate the existence of trophic centres, just as the atrophy noticed in limbs affected by infantile paralysis has been proven to be in connection with and due to atrophy of the large ganglionic cells in the anterior cornua.

ON THE PRESENCE OF NEEDLES IN THE SUBCUTANEOUS TISSUES—THEIR MIGRATIONS.

In a clinical lecture recently delivered in the Hôpital Charité, Dr. Desprès has communicated some interesting facts respecting the singular toleration of needles by the subcutaneous tissues, and the migrations of these bodies. He relates the case of a young man, who, with the leg flexed on the thigh, falling on the anterior aspect of the knee, violently hit this part of the body against a long darning-needle, which was driven into the joint and disappeared. The youth con-

tinned to walk about as if nothing had happened. Four days after he appeared at the clinic. He then complained of severe pain in the popliteal region. Dr. Desprès examined this region and readily found and extracted the needle. Here the needle had traversed the joint and penetrated the popliteal space.

The migration of needles in the tissues is a well attested fact. Otto, of Copenhagen, communicates the case of a young girl, a patient of his, who had swallowed an immense number of needles, and two hundred and ninety-five of these were extracted from different parts of the body. Twenty-two were removed from the left breast.

Villars had a similar patient, a hysterical girl, who habitually swallowed quantities of pins and needles. "The pins advanced more rapidly than the needles. The patient describes the progress of the needles as being more painful, despite its slowness, than that of the pins."

With regard to the extraction of these foreign bodies, Desprès advises to "make haste slowly," unless the needle can be actually felt and fixed under the skin.

Cutting down on the supposed site of the needle, and groping for it with the probe and forceps, is apt to be disappointing. If the needle can be clearly felt in the subcutaneous parts, the point can generally be pushed through by a little skillful manipulation, so that a cutting operation will be unnecessary. Such foreign bodies seldom if ever produce abscesses.

RAILWAY MEDICAL SERVICE.

A circular has been issued by A. A. Talmage, fourth vice-president of the Wabash railway, stating that it has been determined to establish at an early date a hospital for the care and treatment of employees. Suitable buildings will be erected at a convenient location, and rules are laid down governing the admission of patients. Notice is given that after June 1, 1884, the sum of fifty cents each month will be retained from the wages of every man paid \$50 per month or more, and thirty-five cents from other employees. All

employees of the road will be entitled to the benefits of the hospital. Injuries received in fights or brawls or the result of vicious or immoral habits will not be treated at the hospital's expense. The Missouri Pacific adopted the hospital plan five years ago, and the contributing employees endorse the system fully.

This is an example which we earnestly hope will be imitated by all the other leading roads before many years. A medical service of this nature should form part of the organization of every line. The liability to accidents is at all times present, and it is a plain duty of the company to take all reasonable precautions that passengers and employees shall suffer as little as possible from the inevitable risks to which they are exposed.

The method of deducting a certain sum from the wages of the men to meet the expenses of the medical service may seem a little hard, but this should be regarded in the nature of an insurance against accident. It will be amply compensated by the certainty of prompt and efficient surgical aid in case of injury.

THE PARASITES OF MONEY.

To the carriers of infectious material, money has at last been added. Recently, Prof. Reinsch in Erlangen (*Allg. Med. Centr. Z.*, 31, '84), examined a number of coins, and found, to his astonishment, that all coins which showed some encrustation, little sediments, etc., on their surface, contained living bacteria. R. then collected coins of all nationalities, and made the same observation in all coins that had been in circulation for a number of years. When the adherent dirt-particles are removed with a perfectly clean (aseptic) knife, and dissolved in distilled water, a sufficiently powerful microscope will at once reveal the bacteria. The dirt sticking to coin seems to offer to these microzymes a soil specially fertile and favorable to their development. Considering the immense circulation of money passing through millions of hands, it may be probable that coins form no small factor in the transfer of zymotic diseases.

A series of coins which had for some years been in circulation were freed from their dangerous parasites by placing them in a mild, boiling solution of caustic potash, which, by removing all dirt and dust-particles and all incrustations from the coins, liberated them also from their by no means innocuous tenants.

NOTES AND COMMENTS.

Antiseptic Inhalations in Phthisis.

Dr. C. Nelson Gwynne publishes a paper on this subject in the *Medical Press*, May 7, 1884, in which he says that while he believes that the bacilli are reasonably secure from the action of antiseptics, yet as a valuable adjunct to the general treatment he is convinced of their very great importance. The almost unanimous opinion regarding their value by the patients themselves confirms him in his opinion. That they "ease the breathing," "assist up the phlegm," "lessen the phlegm," are the expressions he daily hears regarding them; and the benefit derived is so great that many of his patients make use of the respirator-inhalers much more frequently than he had recommended, and after many months of experience still are as firmly convinced as ever of the benefit they receive from their use. The principal ingredients he has used are carbolic acid, creosote, thymol, iodine, and turpentine; and all these his patients have had no difficulty in using, nor had any dislike to, with the exception of the iodine. The etherialized tincture is, he finds, well recommended; but he could never induce his patients to make use of it for any length of time, nor did they speak favorably of the benefit derived from it.

There are a great number of antiseptic respirators in use, but the one he generally adopts is Dr. Wm. Roberts'. It is of blackened metal, perforated with large holes at the front, shaped to the lips, and half or three-quarters of an inch in depth, with a hinged lid which opens outwards, and allows the introduction of some cotton wool saturated with the material intended to be inhaled. There can be little doubt that impregnating the air of the room with antiseptics will finally take the place of respirator-inhalers, and already many plans have been devised for doing this. If towels saturated in carbolic acid are hung in a room, it has been found that after a few hours nearly all the carbolic acid will have disappeared from the towels, and will have been

taken up by the air of the chamber. Of all the antiseptics, creasote perhaps holds the highest place for this purpose. There are well authenticated cases recorded of phthisical cases having quite recovered by engaging in the manufacture of this article.

Treatment of Whooping-Cough.

Thus far, the treatment of whooping-cough has not been very satisfactory. Bromides, chloral, morphia, belladonna, asafetida, quinine, have all been tried in vain. Careful treatment of the accompanying catarrh, keeping the secretions going, the application of an asafetida plaster to the chest, decided doses of quinine and an occasional dose of chloral at night to insure sleep, seemed to constitute the most successful procedure.

Recently, Dr. Moncorvo, in Rio de Janeiro, has written a monograph on whooping-cough. His observations, which are rather extensive, have led him to the following conclusions:

1. Whooping-cough, the nature of which, until recently, was the subject of the greatest dispute, seems, to judge from the latest clinical observations and microscopical examinations, to belong to the zymotic diseases.

2. The disease seems to be due to the presence of micrococci, which develop themselves to an alarming degree in the mucous membrane of that part of the larynx situated below the glottis, and infiltrate the epithelial cells.

3. Resorcin, applied directly to the mucous membrane of the larynx, has not only diminished in a very short time the number of the attacks of coughing in cases in which it was employed, but it has also decidedly cut short the course of the malady. (*Allg. Med. Centr. Zeit.*, 31, 1884.)

The best method of applying resorcin in these cases is its administration by an atomizer. If this cannot be had, it should be blown in the usual manner into the larynx by the aid of a quill. The only trouble is that whooping-cough is apt to attack young children, and that in them all direct applications to the larynx are difficult to execute. The internal administration of resorcin is, however, utterly useless.

A Convenient Method of Applying Antipyretic Treatment.

Dr. George Mundie thus writes in the *Brit. Med. Jour.*, April 12, 1884:

"A married woman was suffering from general pyrexia complicated with erysipelas. The temperature rose to over 106° Fahr., and seemed to threaten a fatal issue; and I had strongly urged

had been used for one of them, happening still to be in the house, I had it filled with water, and substituted for the bed on which she lay, placing only a single blanket between the patient and the bed. The result was that in six hours the temperature had fallen two degrees; next day it was 103° Fahr., and the patient ultimately made a good recovery. It has since occurred to me that a water-bed might often be made serviceable, when an actual water-bath could not be employed.

"The second case was that of a child aged about four, who had been suffering from diarrhœa. I saw it at my surgery twice; and a week after the last occasion I was sent for hurriedly, and found that the child, although it had been out and seemed very well that day, had been suddenly seized with rigidity of all extremities. The intellect was quite clear, and the child was smiling, and seemed happy. Next morning it was seized with strong convulsions, the temperature having risen to 107°. I immediately placed the child in a bath, bringing the temperature down about 1.5°. I could not, however, prolong the bath as I wished, although it evidently gave relief. I was unable to have the bath again used, and the child succumbed the same evening. When the child had been brought to me, there was nothing to indicate any severe illness. I made a post-mortem examination, and found extensive ulceration of the bowels (typical), especially in Peyer's patches. I then regretted the bath had not been given a more effectual chance, as it was evident that a reduction in temperature was what was indicated."

Partial Inversion of the Uterus by Tumors.

The patient was suffering from a polypus-like tumor prolapsing into the vagina. The tumor began at the posterior wall of the uterus, was removed with scissors, and in consequence of partial inversion of the uterus, perforation of the latter took place. The severe hemorrhage ensuing caused Dr. Werth (*Arch. f. Gyn.*, xxii. p. 65,) to proceed to total extirpation of the organ. The recovery was slow but perfect. Referring to the case Dr. W. remarks, that heretofore too little attention had been paid to the inversion of the uterus, induced by tumors, and he explains the morbid process by contending that the walls of the organ become weakened, and that in consequence of the continuous pressure exerted by the growing tumor, the neck of the uterus is widened

to such an extent, that by the also continuous traction of the tumor a partial inversion is bound to happen, as all favorable conditions—flabbiness of the walls, dilatation of the neck, persistent traction—are permanently present in these cases. For the removal of these tumors W. recommends their enucleation after laying open the capsule, to treat them, therefore, as interstitial myomes.

Cortical Hemiplegia with Word-deafness.

A man, æt. 37, who seven years before had been infected by syphilis, had in the year 1878 an apoplectic attack with right-sided, and 1879 one with left-sided hemiplegia and aphasia. Three months later the aphasia had disappeared. The year following he was again seized with apoplexy, followed by left-sided hemiplegia, aphasia, and now also word-deafness. The patient had at his disposal but a few words; his faculty of hearing, as has been well proven, is intact; but he wants the understanding for spoken words; neither can he read written words. Psychological disturbance has not been noted. Without any change in his condition, in 1883 death suddenly ensued. The post mortem showed: Destruction almost of the whole right posterior central convolution, of the parts of the superior parietal lobule near it, and of the gyrus supramarginatus. Oppenheim (*Centrlb. f. d. m.*, W., 15, '84,) declares this lesion to explain the hemiplegia sinistra. In the left hemisphere a partial destruction of the first two temporal convolutions was found, which had to be considered as the cause of the sensory aphasia.

Hepatic Abscess.

A paper, by Dr. S. West, upon Multiple Abscesses in the Liver, at the Clinical Society of London, March 14 (*Med. Times and Gaz.*, March 22, 1884), gave rise to a discussion of some interest. Numerous cases were cited of hepatic abscesses owning no primary cause outside of the liver it-

Poisoning by Hemlock.

Several cases of poisoning occurred recently among the boys belonging to the training-ship Cumberland stationed on the Clyde, Scotland. It appears that a detachment of the boys was on shore for walking exercise, and several of them amused themselves by collecting various roots and herbs growing near the shore. Of one of these roots a number of the boys partook, believing it to be harmless; but, shortly afterwards, all who had eaten of it were attacked by sickness and other signs of poisoning. No less than ten became seriously ill, the chief symptoms being great stupor and loss of power in the limbs. Steps were quickly taken to obtain medical aid, and, under proper treatment, all eventually recovered; but considerable anxiety was felt for some time in reference to five of the cases that were removed to the infirmary, the state of unconsciousness having lasted for some hours. An examination of the herb showed that it belonged to the umbelliferæ, and was one of the hemlock species.

Treatment of Condylomata.

Salicylic acid and boracic acid are both very good remedies in syphilitic condylomata. Formerly, we often used to remove larger warts of that kind with the scissors, and then cauterized the wound; but since we have been employing the following powder, which is dusted three times daily over the new growths, we have never had occasion to have recourse to any other remedy:

R. Hydrarg. muriat. mit.,	gr. xxx.
Acid. borac.,	gr. xv.
Acid. salicylic,	gr. v.
M. f. pulv.	

All moisture and disagreeable odor at once ceases, and who has not seen the effect of this powder, would scarcely believe it: the condylomata almost visibly dwindle away.

Hysteria in the Male Sex.

Cases are not extremely rare where hysteria occurs in males, but one was recently reported to the Parisian Société des Hôpitaux which offered a striking peculiarity. A young man with a number of hysterical symptoms suffered also with constant pain in the iliac region, just where in women the ovary is located. Dr. Joffroy explains this by the presence in man of an important nervous plexus situated beneath the location of the ovary in woman. This is the seat of the pain in both cases, and the tender ovary of hysterical women is principally an example of nervous sympathy.

Pilocarpine in Puerperal Eclampsia.

As of interest in connection with the cases which we have already reported, we note in the *Med. News*, April 26, 1884, that Dr. E. L. Marchal, of Alabama, reports a successful case. One single dose of one-fifth grain of muriate of pilocarpine was given hypodermatically, and though the women lay comatose for twenty-four hours, there were no more convulsions. Dr. M. thinks that pilocarpine is especially indicated where there is, as it were, a locking up of the secretions.

Studies on Alcoholism.

Dr. Mierzejewski, of St. Petersburg, has recently given much study to the results of the abuse of alcohol. He thinks that the impurities of distilled liquors have much to do with their hurtful effects. He commends, therefore, the example of Belgium, which applies the whole tax on drinks to maintaining the sanitary police, part of whose duty is to secure purity in the beverages. This suggestion of his is also worthy of the attention of our own legislators.

New Test for Albumen.

Dr. G. Johnson recommends as the surest and most reliable test for albumen, picric acid in powder form. The smallest possible quantity of the powder, added to the undiluted urine, will at once reveal the presence of albumen.

The Relations of Ovulation and Menstruation.

This much-discussed question seems no nearer a definite conclusion than ever, for we find in a long article on the subject by Mr. Lawson Tait in the *London Medical Times*, May 10, 1883, that af-

ter looking carefully into the subject he is satisfied that the evidence so far has completely destroyed the ovular theory of menstruation. Yet in the same paragraph, he says that he is persuaded that the investigation is worth further perseverance.

SPECIAL REPORT.

OPHTHALMOLOGICAL MISCELLANIES.*

BY CHARLES S. TURNBULL, M. D., PH. D.

In reviewing the literature of ophthalmology we have been induced to note a few of the novelties of this special branch of the practice of medicine, because we feel confident that many interesting and unique cases must be lost to those who do not have time enough to read all that is published in the several special journals throughout the world. Unless one is working day by day in this special field, he can form no idea of the vast amount of literary work annually published by ophthalmologists at large. The eye is divided and subdivided, and studied macroscopically as well as microscopically, some workers even devoting large portions of a lifetime to the embryology of but a part of the optical apparatus.

We are indebted for most of this material contained to the *Archives of Ophthalmology*, edited in English and German, and issued quarterly by Drs. H. Knapp, of New York, and C. Schweigger, Berlin, in conjunction with more than half a hundred of distinguished men throughout all parts of the world, each contributing to make up a volume of over 500 pages of rich and rare literature. When we consider that this constitutes but a portion, much less than half, of all that is written, it is easy to imagine how impossible it would be for any one man in active practice, to read all that might, even on account of its novelty, be of interest to him.

To look back over a period covering about three years, and without reference to a special date, we would notice the use of a "magnet" for the removal of particles of steel and iron from the interior of the eye, devised by Gruening, of New York; the same instrument has been used for the removal of pieces of steel from the anterior chamber, and cornea; another for the detection of the presence and location of pieces of steel and iron in the eye by the indication of a magnetic needle, by Pooley, of New York.

Hirschberg reports the successful removal of a

piece of iron from the eye, and Jany a chip of iron from the vitreous, with the electro magnet; he says, "real triumphs are gained with the magnet only in those cases where we have to deal with a piece of iron which has but recently entered and is suspended in the vitreous, and which, with forceps, hooks, and spoons, can but rarely be removed without permanent damage to the eyeball."

Magnus recalls the fact that the magnet had been used as early as 1646 by Fabricius Hildanus, and, as he expressly mentions, at the suggestion of his wife.

Jeffries, of Boston, removed a piece of iron from the eye by the electro-magnet through a corneal section, and Oppenheimer removed another through a scleral section; Gruening's magnet was used in this case.

Herman Schafer, in speaking of the effects of eserine and the mydriatics atropine, duboisine, homatropine and hyoscyamine, states in regard to the influence of eserine upon the three agents, atropine, duboisine, homatropine, that it counteracts the effects of homatropine completely and permanently; that of duboisine, and more particularly that of atropine, however, only when instilled in larger quantities, and then only for a brief period, after which it yields again to the effects of the latter.

In general, it is sufficiently demonstrated that, as respects the dilatation of the pupil, atropine, if somewhat slower, possesses a more lasting influence than duboisine; that the latter dilates the pupil in a shorter time, and momentarily acts more energetically, but loses its influence more quickly; finally, that homatropine develops its influence in a briefer time than either of the other agents, but produces a lesser dilatation of the pupillary diameter, and is the first to decline in its effects. The degree of concentration in which the homatropine is employed is apparently without influence upon the duration of the effect.

The accommodation is paralyzed more rapidly by duboisine and homatropine—by DUBOISINE even a little more so than by homatropine; with the latter, however, the normal state returns in twenty-four hours, with duboisine after three to four days. Paralysis of the accommodation by atropine proceeds very gradually, and persists the longest.

In accordance therewith would be the practical application of these three agents. Were it desired to secure simply dilatation of the pupil for the purpose of examining the fundus, or to paralyze the accommodation for the certain determination of the state of refraction, homatropine is decidedly to be preferred to the other drugs.

*A paper read before the Alumni Association of the Auxiliary Department of the Medical Department of the University of Pennsylvania, April, 1884.

Risley concludes, "That for the correction of anomalies of refraction in otherwise normal eyes, the homatropine is to be preferred."

If, on the other hand, a therapeutical effect is desired, homatropine is to be set aside, on account of its insufficient and too restricted effect, and the application of atropine and duboisine can alone enter into consideration.

Risley, from a therapeutic standpoint, concludes "That if retino-choroidal disturbance is also present, hyoscyamine or duboisine are preferable, (a) to atropine, because of the shorter duration of the treatment; (b) to homatropine, because of their more persistent control over the ciliary muscle; and that hyoscyamine is preferable to duboisine, since the tendency to systemic poisoning is not so great.

Shäfer recommends the use of duboisine in iritic conditions, with or without extensive synechiæ, where atropine had been employed for some length of time, and with but partial success, on account of conjunctival and ciliary injection. Duboisine, he says, never causes conjunctival irritation, and even diminishes that caused by atropine. And we cordially endorse the recommendation of duboisine in iritic conditions. Knapp says of quinine amaurosis that the characteristic features, according to Roosa, Wecker, Voorhies, Michel, Gruening, and himself, are:

1. Total blindness subsequent to the taking of large quantities of quinine.

That the total blindness, in all the cases thus far made known, was only temporary.

2. Pallor of the optic discs.
3. Marked diminution of the retinal blood-vessels, in number and calibre.
4. Contraction of the visual field.

K. mentions some other symptoms: "1. Diminution of the color-sense (red-green, then green blindness); 2, diminution of the light-sense (as if a veil was over the eyes); 3, the pupils during the total blindness are irresponsive to light, but (Gruening) move on accommodative efforts; 4, anæsthesia of the cornea; 5, impairment of hearing, to total deafness and tinnitus aurium in every case, though transient."

The subjective noises and deafness, though exceedingly frequent symptoms of quininism, are always transient, at least he has not been able to trace one case of persistent deafness or tinnitus aurium to the use of quinine alone. (L. Turnbull has long since emphatically expressed himself in a similar way.) The impairment of sight, he says, will disappear entirely in the mild cases, whereas in the severe typical ones the restoration of the central acute-

ness of vision seems to be complete only in a certain number of cases; in almost all, however, a fair amount, $\frac{20}{100}$ to $\frac{50}{100}$ of S., is regained. The contracted visual field expands slowly, commonly does not reach its natural limits again.

The progress of quinine amaurosis, even in advanced cases, is, on the whole, good, as there is thus far no case of permanent blindness on record, and the typical, i. e., fully developed cases, are very rare. How frequent the mild cases are, and how rapidly they recover, remains for further investigation to ascertain. No beneficial mode of treatment seems yet to have been discovered. The "depleting therapy" to which V. Graefe ascribes the recovery in his second case will, in view of the marked ischæmia of the retina discovered of late, scarcely find any advocates now. Nitrite of amyl, given in the way of inhalation, by Voorhies, Gruening, and Michel, showed no effect. Strychnia and other remedies, as well as electricity, were likewise inefficient. Horizontal position, as long as the general anæmia, and particularly that of the brain and eye, are marked, seemed beneficial. Generous diet, with perhaps gentle stimulants, and as soon as practicable sojourn and exercise in a healthy, invigorating atmosphere, appear rational means of recovering strength, and supplying the retina with what it most needs—blood.

Chisholm uses the actual cautery needle in the treatment of conical cornea. The operation is performed with a fine sewing needle, heated to whiteness in an alcohol lamp, and thrust through the apex of the cone. The subsequent cicatrization causes the flattening of the cone. Dr. C. also uses a needle designed for the destruction of the hair-bulbs, in cases of displaced cilia, by electrolysis. It consists of a needle set into a handle, which is introduced cold into the root of the hair-bulb. By pressing on a button connection is made, and the needle becomes heated, and the electrolytic action is manifest by the bubbles of gas escaping.

Wall reports a case of congenital absence of the eyeballs, "anophthalmia." The tutamina oculi were perfectly formed, but there were no eyeballs, even in a rudimentary form. The lachrymal gland was present. The child was a white male, and six months old.

Ayers mentions concerning the physiology of the visual purple, and sums up his conclusions as follows: "We know that the purple is a photochemical substance which is sensible to light, and that its seat is in the outer segments of the rods, whereas it is never found in the cones. The cones, on the other hand, being the only ele-

ments found in the fovea centralis, we are forced to the conclusion that distinct vision, both for objects and for colors, is independent of its existence. In the higher classes of animals it is sensitive to light, but in some deep-sea fishes, cephalopods, etc., it has its seat in the rods, but is no longer sensitive to light, although it has the same color as before. Where it is not sensitive to light, the optical structure of the eye is very defective. It is an albuminoid compound, and is a secretion of the pigment epithelial cells of the retina; but this secretion is not controlled by any of the larger nerve-trunks, which have a part to play in the functions of the eye. We know of no drug which can diminish its secretion, but pilocarpine and muscarine greatly increase it."

Galezowsky reports a case of *congenital irideremia*, (absence of the iris) through several generations.

Wolfe (Glasgow) reports a case of *bleeding tumor of the iris*, about four mm. in diameter, bleeding every four to six weeks.

Chisholm reports a *piece of metal in the eye for twenty-three years* without causing sympathetic ophthalmia.

Bremer, among 223 deaf mutes, found nine cases = 4 per cent. of *retinitis pigmentosa*.

Haffner reports the *rare migration of a round worm 3 cm. in length, into the left lower lachrymal canal*, in a child suffering from severe whooping-cough.

Sigismund reports a *small splinter of wood kept in the eye for forty-seven years* without any disturbance.

As ophthalmological anomalies, Keyser reports three cases of *congenital dislocation of crystalline lenses* (ectopia lentis); in one, aged twenty-six, the lenses were dislocated differently, but not symmetrically, as is usually the case. In the right eye, the lens was dislocated inward, and the left eye directly upward. In the other two cases, which were also anomalies, the lenses were dislocated directly downward, entirely out of the region of the pupil. These two cases were daughter and mother.

A case of *double pupil, diplokorina*, in but one eye of a lady aged twenty-six. There was a broad band $1\frac{1}{2}$ mm. in width, running across, from margin to margin of the iris, at an angle of 110° . It extended only from the extreme pupillary edges of the iris, and was of the same thickness and color, and continuous structure of the iris. Patient had never suffered from any inflammation of the eye. As a congenital anomaly of the iris, it was rare, as occurring in but one eye.

(To be continued.)

CORRESPONDENCE.

Vomiting During Pregnancy.

EDS. MED. AND SURG. REPORTER:—

Mrs. ———, multipara, in the second month of pregnancy was taken with intense nausea, followed in a few days by vomiting. This condition lasted three weeks, during which time my patient was brought to the very verge of the grave. Every prominent and boasted specific was used, including "pop-corn" and "ingluvin;" every one was rejected as soon as taken, notwithstanding our perseverance with them—"usque ad nauseam"—and she positively declared that my remedies were worse than her disease.

Everything, however, bland and unirritating, was almost instantly rejected, and even the very mention of any article of diet induced violent retching. For eleven days not one particle of food was taken and retained a moment. My patient's brain became affected. She talked at random, believed that her whole abdomen was being pulled out, piled pillows on the stomach to hold it down, etc. Pulse feeble and rapid, with intense thirst. My patient was starving to death. To produce abortion now was seriously considered, but fearing its after effects, we concluded to try other remedies. Believing, from her condition, that if I could bring her power of will to assist, I commanded her to take one-half teaspoonful of "Beef Peptonoids," by Reed & Carnick, every half hour. For twelve hours this was retained partially, but after that time it too was rejected. She had gained a little. Our next resort was a dernier one, as we supposed, to "Horsford's Acid Phosphate," and chicken water, which, we are happy to say, acted like a charm. The nausea and vomiting ceased, and my patient is to-day in her usual health. JOHN W. AYLER.

Poolesville, Md.

A Unique Recovery from Wound of Knee-joint.

EDS. MED. AND SURG. REPORTER:—

During an experience of over thirty-nine years, I have met with a good many singular cases of gun-shot wounds. But on May 11, 1871, was called to a case which terminated in a way, as far as I can learn, which may truly be termed unique.

Ben Grant, aged about 29 (colored), hauled a load of goods from the river, and with it a musket charged with duck-shot; taking out his freight, he took the gun by the muzzle and pulled it out of the rear of the wagon; it was discharged, with the muzzle nearly touching the patella; horizontally across that bone the charge passed, and carried away four-fifths of it as neatly as if cut out with a gouge. Neither the condyles nor any other bone was injured. I determined to see if the knee could not be saved. Approximated the edges of the huge gap with long strips of adhesive plaster, gave him a few doses of morphine to be taken at stated intervals, and left a lotion composed of carbolic acid, glycerine, whisky and water, to be constantly applied on the wrapping over the wound; visited the case for several days to note progress, etc. If he had any fever, it was scarcely

perceptible; suffered but little pain; the wound had no unhealthy symptoms. He was kept supplied with the lotion for a long time. To my astonishment, after taking out the small remnant of patella left, on account of necrosis, and keeping up passive motion of the knee-joint, the wound gradually healed, and in about eleven months was well. He now has as serviceable a knee-joint as he ever had, and can perform any labor, and has done so for nearly twelve years.

I examined the leg a few days ago; there seems to be nothing which fills up the gap of the lost patella; no union of the tendon of the quadriceps and ligamentum patella, but simply a vacancy. How the complete motion of the knee-joint and its strength are maintained, is a mystery to me.

If any one who reads this article has ever seen, read, or heard of such a case, please let it be known.

G. R. RAMSAY, M. D.

Lawtonville, S. C., April 23, 1884.

Rheumatism of the Stomach.

EDS. MED. AND SURG. REPORTER:—

G. W. S., M. D., asks for the suggestion of a treatment for the case of his female patient. It may be presumed that he has made his diagnosis, and that the case is one of those obstinate and curious nervous and rheumatic affections which so often attack females about the age of his patient. It is best not to wait for the return of the pain, but to commence treatment at once by the application of six or eight leeches to the epigastric region if the slightest tenderness or pain should be evinced by pressure over the pit of the stomach. The leech-bites should be allowed to bleed for two or three hours, and in a day or two a flying blister, three inches by four, be placed upon the accustomed seat of the pain. A powder composed of six grains of calomel and eight of rhubarb, should be given at bed-time, and followed in the morning by a saline purgative to stimulate the bowels and liver to a healthy action. This powder may be repeated once a week, and after the action of the first dose, the following pills and mixture should be regularly taken:

R. Sulphate of quinine,	grs. xxj.
Pulv. ferri sulph. (sic.),	grs. vij.
Pulv. aloes (sic.),	grs. iij.
Pulv. capsicum,	grs. vij.
Syrup,	q. s. M.

In 21 pills divide. Sign.—Three pills three times a day before each meal; and,

R. Iodide of potassium,	ʒj.
Vin. colchici sem.,	ʒiij.
Syrup simple,	ʒjss.
Aqua destil.,	ʒiv. M.

Shake well and take a tablespoonful three times a day after each meal. Should the patient be restless at night, I would give:

R. Bromide of ammonium,	ʒj.
Bromide of sodium,	ʒij.
Tinct. henbane,	ʒss.
Syrup simple,	ʒij.
Aqua menth. pip.,	ʒiv. M.

Shake well. Sig.—A tablespoonful or two at bed-time. I would repeat the blister once a month, and continue the treatment for two or three

months, varying it according to the physiological effects of the medicines prescribed. Electricity may also be used. J. B. JOHNSON, M. D.

Washington City, D. C.

NEWS AND MISCELLANY.

How Liston Reduced an Obstinate Dislocation.

In an address published in the *Edinburgh Med. Jour.*, May, 1884, Dr. Alexander Keiller relates the following amusing anecdote of the great Liston:

"We have already referred to his powerful build, the mere appearance of which was more than enough to make even the biggest bruiser hesitate before encountering Liston's fisticuff, in either the noble or ignoble art of self-defence; and in thinking of our present hero as an object of physical power, we shall here cite the particulars of a case which went to exhibit his force of skillfully-applied will as well as muscular dexterity. A strong fellow of a carter was one day admitted into the old Infirmary in consequence of an overlooked dislocation of the shoulder-joint, which puzzled the surgeons on duty to reduce, especially as their repeated attempts at reduction were greatly frustrated by the too obviously determined resolution of the obstreperous and unusually resisting monster of strength, whose unmanageable muscularity Liston was afterwards induced to alone cope with and subdue, and which created a scene more akin to that of bull-baiting than to human surgery.

"We were fortunate enough to witness this new trait of tact as well as of strength, and on the still unsubdued and as yet unrelieved animal being again led into the enclosed ring, he was immediately pounced upon by the herculean Liston, who at once firmly grasped the obviously fixed, because immovably dislocated extremity, and which he continued powerfully to pull and twist, and then to violently manipulate, under a perfect storm of the most dreadful oaths and personal kicks, even against the region of parts by no means well or safely protected. Liston, however, was quite equal to the awkward situation, and as every kick with dangerous force was launched at him in front, he knew his anatomy too well not to swing round so as to receive them on amply-cushioned parts behind, until his own time came to return the madman's blows and imprecations with confounding, and at the same time most successful interest; for, while engaged keeping up the extension required to overcome, if possible, the muscular contraction in order to facilitate the reduction aimed at, Liston knowingly and cleverly seized his opportunity, the most precious opportunity in such cases, of staggering the muscles into comparatively flaccid abeyance. Liston, while keeping up the extension with one of his big and powerful fists, and fiercely eyeing his still cursing and kicking surgical victim, loudly exclaimed: 'You d—d scoundrel, what are you swearing at?' and with one momentarily-released right mighty hand struck him a bang between the eyes, when immediately, through Liston's masterly manœuvring, in popped the stubborn joint of the now hanged-up-eyed carter, who ob-

vionsly failed to appreciate either the laughter or the applause of the audience."

Connecticut State Medical Society.

The following papers were read at the ninety-third annual convention, held at New Haven, May 28 and 29:

"The Medical Profession and its Claim to the Respect and Gratitude of the Community," by Dr. E. B. Nye, of Middletown. "Medicine, Fifty Years Ago," by Dr. R. W. Matthewson, of Durham. "Points on Strangulated Hernia," by Dr. G. W. Harris, of Old Lyme. "Stone in the Bladder," by Dr. W. H. Carmalt, of New Haven. "An Unsuccessful Case of Wiring a Simple Fracture of the Patella," by Dr. Carmalt. "Subtrochanteric Osteotomy," by Dr. Carmalt. "Extirpation of the Tongue for Cancerous Disease," by Dr. Carmalt. "An Ulcerating Mucous Patch of the Vulva, with Condylomata about the Anus," by Dr. F. E. Beckwith. "The Germ Theory of Disease," by Dr. N. E. Wordin, of Bridgeport. "The Treatment of Conjunctivitis," by Dr. F. M. Wilson, of Bridgeport. "The Early Diagnosis and Treatment of Potts's Disease," by Dr. George B. Packard, of Hartford. "Malarial Diseases Cured without Quinine," by Dr. Ambrose Beardsley, of Birmingham.

Officers for the ensuing year: The nominating committee presented the following list of officers, for whom the Secretary was instructed to cast the ballot of the Society:

President—B. N. Comings, of New Britain.

Vice-President—E. C. Kinney, of Norwich.

Treasurer—E. P. Swasey, of New Britain.

Secretary—S. B. St. John, of Hartford.

Missouri State Medical Association.

At the twenty-seventh annual session, held in Sedalia, May 20, 21 and 22, the following papers were read: "Eczema," by Dr. H. Ohmann-Dumesnil, of St. Louis. "The Cause and Cure of Quackery and Quackery," by Dr. G. M. Dewey, of Keytesville. "A Case of Slow Pulse," by Dr. Glasgow, of St. Louis. "Neoplasms from a Practical Standpoint," by Dr. E. H. Gregory, of St. Louis. "Idiopathic Sarcoma of the Skin," by Dr. Hardaway, of St. Louis. "Periodic Pains Caused by Diseases of the Womb and its Appendages, not Relieved by Anti-periodics," by Dr. P. V. Schenck, of St. Louis.

Officers for the ensuing year:

President—Dr. H. H. Middlekamp, of Warrenton.

Vice-Presidents—Drs. T. F. Prewitt, of St. Louis; W. E. Evans, of Boonville; B. G. Dysart, of Paris; H. W. Lane, of Jasper; S. G. Griswold, of New Haven.

Recording Secretaries—Drs. J. H. Thompson, of Kansas City; N. M. Baskett, of Moberly.

Corresponding Secretary—Dr. F. J. Lutz, of St. Louis.

Treasurer—Dr. C. A. Thompson, of Jefferson City.

After reading several papers by title, and referring them to the Committee on Publication, the Association adjourned to meet in St. Joseph, on the second Tuesday in May, 1885.

Louisiana State Medical Society.

At the annual meeting held at *Baton Rouge*, May 21, 22, and 23, the following papers were read:

"Annual Address," by Dr. Davidson. "The Principles Controlling the Mind and Directing the Tendencies of the Age," by Col. K. A. Kross. "Acute Plastic Iritis," by Dr. Bruns, of New Orleans. "The Spleen; its Anatomy, Pathology, and some of its Lesions," by Dr. G. B. Underhill, of New Orleans. "Tetanus and Tetany," by Dr. M. Schuppert. "Contagion and Germs," by Dr. Hardie. "Cremation," by Dr. F. Formento, of New Orleans.

Officers for ensuing year:

President—Dr. R. H. Day, of East Baton Rouge.

Vice-Presidents—Drs. C. J. Bickham, of New Orleans; E. S. Lewis, of New Orleans; T. J. Buffington, of East Baton Rouge; C. M. Smith, of Franklin; I. J. Newton, of Bastrop; T. J. Allen, of Shreveport.

Nebraska State Medical Society.

At the sixteenth annual meeting, held in Omaha, May 13 and 14, 1884, the following officers were elected for the ensuing year:

President—Dr. F. G. Fuller, of Lincoln.

Vice-Presidents—Drs. G. N. Peebles, of David City, and M. J. Gahan, of Grand Island.

Permanent Secretary—Dr. A. S. Mansfelde, of Ashland.

Corresponding Secretary—Dr. R. R. Livingston, of Plattsmouth.

Treasurer—Dr. R. C. Moore, of Omaha.

Grand Island was selected as the place for holding the next annual meeting.

Hospital Chaplaincies in France.

M. Desprez, surgeon to the *Hôpital de la Charité*, has written to the *Journal des Débats* to state his experience of the working of recent legislation, by which all persons connected with religious bodies are excluded from the Paris hospitals. Himself a Republican and a free-thinker, he nevertheless emphatically condemns the new order of things. The lay assistants who now take the places of the Sisters of Charity at the bedside of the sick are, he declares, far less efficient than the nurses who have been displaced, and he condemns the whole system of secularization which comprises the suppression of hospital chaplaincies, as contrary to the interests of the poor.

A Growing Interest in Hygiene.

At the late meeting of the Louisiana State Medical Society, the Committee on State Medicine reported through its chairman, Dr. S. E. Chaillé, of New Orleans, that it had placed in the hands of Judge Sery the following subjects, to be elaborated into bill form, and presented to the General Assembly:

Law for the creation of a State Board of Health, whose members shall be selected from the various districts of the State.

Law requiring the teaching of hygiene and elementary physiology in the public schools.

Hardness of Hearing in Children.

Dr. Gellé, of Paris, has discovered that about 20 to 25 per cent. of school children can only hear within a limited range. It has also been noticed that the poorer classes of children are specially liable to this affection, the fact being explained by the want of attention to trifling ailments of the ear. In France a practical result has ensued from the above observations, it having been arranged for children to be placed at a distance from the teacher's desk which would correspond with the strength of their hearing.

Pepper Succeeds Stille.

At a meeting of the Board of Trustees of the University of Pennsylvania, held on June 3, Dr. William Pepper was elected to the Professorship of The Theory and Practice of Medicine, rendered vacant by the resignation of Dr. Alfred Stillé.

Items.

—In the *London Med. Times*, Dr. Herbert Collier recommends the local application of sulphurous acid in lupus vulgaris.

—Dr. H. R. Davenport, of Nanticoke, Pa., is reported to have fallen dead recently while engaged in dressing a wound.

—In the *Peoria Med. News*, May, 1884, Dr. Robert Boal reports the case of a woman who had retained a glass pessary in her vagina for twenty-one years.

—The state of Texas has virtually declared non-intercourse with all ports and places south of 25° north latitude, and Matamoras quarantines all travel by land from points south.

—A young man has died in England, probably from tetanus, the sequel of a wound of the elbow received in a struggle with a panther in China some months previously.

—An attempt is being made by some of the American Prison Societies to establish at Washington a permanent central office for the collation of the criminal statistics of the United States.

—Professor Purjesz, of Buda-Pesth, states that he has found Friedländer micrococci of pneumonia in other diseases, and has not always found them in pneumonia. He denies the infectious character of the disease.

—A case showing the importance of an efficient inspection of meat markets, is recorded from England. Four children and their parents were seized with violent illness as the result of eating calf's liver, and one of the children, aged nine, died. It was found on investigation that the liver came from an animal which had been slaughtered for disease.

—In the *Brit. Med. Jour.*, May 17, 1884, Dr. Arthur E. J. Barker reports a case of aneurism of the popliteal artery, cure by digital compression in six hours and a quarter, after failure of instrumental compression and ligature.

—It is said that by the following simple method almost instant relief of ear-ache is afforded: Put five drops of chloroform on a little cotton or wool in the bowl of a clay pipe, then blow the vapor through the stem into the aching ear.

—The Naval Museum of Hygiene, in Washington, although of recent growth, will be found to possess an interesting collection illustrating sanitary science, together with a good library. The National Museum and the Museum of the Department of Agriculture contain also much that is of interest to members of our profession.

—In the *Brit. Med. Jour.*, Dr. Dobson relates a case of early maternity. A girl who began to menstruate at eleven years of age was delivered by forceps of a male child in February last, being at that date thirteen and a half years of age. She had, therefore, become pregnant at the age of twelve and three-fourths years.

—The *Med. Press* says that no case should be given up as an incurable in which only single remedies have been employed. It often happens that syphilitic patients who exhibit no kind of improvement under iodide of potassium, will get rapidly well if submitted to the influence of mercury; and many other instances might be cited.

—An attempt to isolate the bacillus of enteric fever will probably be made under the stimulus given by the munificent offer of a Fellow of the Linnean Society of New South Wales, to give a prize of \$500 for the best essay on "The Life History of the Bacillus of Typhoid Fever." Compositions must be written in English, and delivered at the Society's house by December 31st next.

In Dalldorf, Germany, a monster was born with the following peculiarities: It was a boy, and lived fourteen hours; it had 16 fingers, eight on each hand, thumb and little finger being double, but the two parts were grown together, and the other fingers were united by a web; otherwise nails and joints normal. It also had sixteen toes, crooked and with joints not fully developed, but nails and single toes plainly discernible. The face evinced a cleft palate, but the most remarkable fact was the utter want of a tongue, while two teeth each were present in front in the upper and in the lower jaw.

QUERIES AND REPLIES.

G. W. S., M. D.—From the brief and imperfect history of your case given (*MED. AND SURG. REPORTER*, May 31, 1884), would infer that the pain in stomach was of a gouty origin, after excluding chronic inflammation and cancer. Would treat the case by *restricting and selecting* the diet in the most careful manner, with reference to amount and digestibility (for more than likely she is a high liver); by the use, internally, of guaiacum and colchicum combined, and given in whisky, or whisky and glycerine; of bromide of lithium given in four parts simple syrup and one of syrup of ginger; all to be given in the usual doses of the agents, and each combination to be given three times a day; and of *French thapsia plaster* as counter-irritant over stomach. Keep up a more or less constant crop of pustules on epigastrium with plaster. Beware of the use of morphia or chloral in such a case, lest you worse your case rather than better it in the result. L. N. DAVIS, M. D.

Farmland, Ind., June 2, 1884.

DEATH.

JONES.—Wednesday morning, April 30, 1884, Dr. H. G. Jones, of Evansville, Ind., in the sixtieth year of his age.

THE MEDICAL AND SURGICAL REPORTER.

No. 1425.]

PHILADELPHIA, JUNE 21, 1884.

[Vol. L.—No. 25.]

ORIGINAL DEPARTMENT.

COMMUNICATIONS.

ON PAROXYSMAL FEVER—NOT MALARIAL.

BY J. H. MUSSER, M. D.,

Physician in Charge of the Medical Dispensary of the Hospital of the University of Pennsylvania; Pathologist of the Presbyterian Hospital.

(Concluded from page 738.)

Not only must pent-up or forming pus be considered a factor in the causation of a periodical fever, but confined serum or forming serous exudation may undoubtedly give rise to intermitting fever. A case of subacute pleurisy with effusion, in which there occurred, in the course of the disease, distinct intermitting fever, came under the writer's notice. The usual evening exacerbations were present, but in the morning the temperature had fallen to, or almost to, normal. So marked were the paroxysms that an empyema was suspected, and doubt only removed by paracentesis, proving the effusion to be serous. Two similar cases have come to his notice in private practice, both in children. The one, a lad 11 years old, had a dry cough for three weeks, with afternoon malaise and fever. The attendant ordered quinine with but little benefit. An examination of the lungs revealed a large collection of fluid in the left pleural sac, which rapidly disappeared under treatment. The temperature was recorded but once daily for obvious reasons, but at times in the morning, again in the evening. Invariably an evening rise, a morning fall, were noted; but it never ranged higher than 102°, and there were no profuse sweats following. From the rapid disappearance of the fluid, and the speedy renewal of

the lad's health, the effusion was called serous, and not purulent.

It may seem very trite to record such simple cases, but when, only lately, a child was seen in consultation, ill from a supposed meningitis, but truly so from an actual serous pleuritic effusion, one should feel that nothing is commonplace, and that it is the little things that need to be constantly dwelt upon. With this remark it may be stated that the fever of pneumonia may be intermitting. Later in the paper, cases of catarrhal pneumonia will be referred to; but now the croupous variety is considered. Four cases, all in children, are recorded in the writer's note-book. Two of the cases were in his care from the first; two were attended by other physicians, coming to him later.

In the first case he was egregiously deceived. The child, *æt.* 4, for five days was well, to all intents and purposes, in the morning, eating and playing about, with possibly only a slight cough. In the afternoon the temperature would rise to a great height (104 $\frac{3}{4}$ °), and the child would be sick until midnight. Repeated examinations of the lung could not detect a pneumonia until the fifth day. He was misled by the absence of dulness and of bronchial breathing, and the occurrence of tympany over the affected lung, as has been rarely noted.

Case number two, of the same character, occurred in a girl 7 years old. A chill, followed by high fever, with nausea and vomiting, substernal pain and cough, marked the onset. Seen the third day, her temperature in the evening was 104 $\frac{1}{2}$ °, with the above symptoms intensified, and a very rapid pulse (140) and rapid respiration (48).

Both the fourth and fifth days the temperature was normal in the morning, high at night. On the fifth day bronchial breathing was first noted at the right base; on the seventh day, dullness; on the ninth day resolution began; after the fifth day the fever was continuous. It seemed like a case of retarded pneumonia—as regarded physical signs—according to the observation of Dr. Andrew Clark.

Following the outline indicated by Murchison, the next form of intermitting fever he discusses is that due to endocarditis. The following case* of ulcerative endocarditis, the febrile range of which was characterized by daily paroxysms, is of interest. There was no difficulty in recognizing the nature of the affection.

TEMPERATURE RECORD.

	A. M.	P. M.
21	1—	103 $\frac{2}{3}$ °
22	100 $\frac{1}{2}$ °	101 $\frac{3}{4}$ °
23	98 $\frac{2}{3}$ °	99°
24	98°	105 $\frac{1}{2}$ °
25	97 $\frac{1}{2}$ °	103 $\frac{1}{2}$ °
26	99°	103°
27	99°	100 $\frac{3}{4}$ °

The writer observed it during life, and deems it worthy of being recorded in this connection.

It would be a great surprise to know how many persons in the latter stages of phthisis, when giving a history of their complaint, say that it was preceded by malaria, or malaria broke them down. Over and over again is such a sad tale told us in the medical dispensary, and it is a matter of fact that not only do the laity, but many physicians, consider early cases of phthisis as malarial in nature, entirely overlooking the local troubles. When speaking of catarrhal fever, the subject will be adverted to again, but the cases of tubercular origin are sometimes none the less examples of intermitting fever, non-malarial. Repeatedly my notes show cases that had been treated for malaria in the early stages. Not only in the formation of tubercle in the lungs, but also in the brain, is the process accompanied by daily paroxysms of fever at times. One case that came under notice was particularly impressive.

The attending physician was going out of town for the summer, and left in the writer's care a little girl five years old, in the fourth week of her fatal illness. She had always been a bright child, of nervous temperament and tubercular diathesis. The illness was of four weeks' duration, marked in the early period by failing in flesh and strength; in the latter period by a chill or chilli-

ness every evening, followed by a night of restlessness and fever. She never complained of headache, nor did she vomit, while her bowels were regular. Eight days before the present attendant saw her, her physician visited her, and attributed the symptoms to malaria; quinine was used. Four days thereafter headache began. The day the writer saw her (fourth week), she had had a slight convulsion and other unmistakable evidences of tubercular meningitis, of which she died in seventy-two hours.

How terrible to be compelled to tell a fond mother the innocent malaria only simulated the baneful meningitis! The writer once made the mistake of attributing a periodical headache to malaria; tubercular meningitis was the cause of the pain. It is seen then, and is well known, that many manifestations of that disease are periodical.

The succeeding case of chronic hepatitis with enlargement, illustrates that form of intermitting fever which is hepatic in origin. The diagnosis was made without difficulty, especially the differentiating from intermitting fever of malarial origin. The following abstract of the history includes all the important points:

George W.,* *æ.t.* 43, German farmer, of Manayunk, contracted diarrhœa during the war, which has always shown some tendency to return. Has had malaria; probably has had syphilis; otherwise been very healthy. Family history good. Admitted September 2, 1877, with well-marked jaundice; emaciated, and presented the symptoms of itching, dark-colored urine, languor and sleepiness, and a small, slow and feeble pulse.

The jaundice appeared gradually in February of 1877, preceded by several days of diarrhœa. Since then marked dyspeptic symptoms, relieved by attacks of diarrhœa; stools at times clay-colored, at times normal. Some œdema of feet, but ascites never detected. October 2, liver from fourth interspace to two inches below margin, on deep percussion, margin smooth and resisting; no pain or tenderness. October 15 to 25, uncontrollable hicough. Extreme exhaustion, rapid emaciation, deepening jaundice, semi-typhoid state; death, November 4. Autopsy revealed the diagnosis to be correct.

The temperature record is noted with the remarks of Dr. Guiteras, whose resident physician the writer was at the time, on its curious range, in order to associate the case with a paper on fevers.

"I find that every third temperature is pretty regularly a high one, the fall being very great in the two intervening temperatures; so that the rise and fall do not present the usual relations to the morning and evening hours. The curious range of temperature may be due to an intermittent absorption of effete products from the liver, or an intermittent arrest of the oxygenating processes going on in the liver, an arrest that must influence the general temperature, if we remember that in health the temperature of the organ reaches 106°."

In another paper* of the writer may be found reported a case of primary cancer of the gall-bladder.

Early, in fact almost until death, the attending fever was thought to be of malarial origin. The writer, as well as others, made the mistake. Until a few months before her death the fever was distinctly intermittent, with chills; later it became remitting, and then continuous. Although there were jaundice and occasional attacks of vomiting, there were no special evidences of localized disease. The spleen was enlarged, and so it was thought to be a miasmatic fever. The change in type, the extreme exhaustion, and the emaciation, caused this idea to be abandoned. Until death it was obscure. A sufficient cause for the temperature range was found at the autopsy in a suppurative inflammation of the bile ducts, and the healthy portion of a gall-bladder, the remainder of which was the seat of carcinoma. One can see now that more stress should have been laid on the occasional vomiting, the slight hepatic tenderness, the previous history of biliary colic, the persistent and deepening jaundice, and the great emaciation, and thereby a diagnosis been made between miasmatic fever and suppurative fever.

Here will briefly be recorded two cases illustrative of the fever of hepatic origin, not because of one difficulty in their recognition, but because one

of them, the first, had been treated for malaria.

This one was the case of M. Mc., æt. 50, who suffered at irregular intervals, often repeatedly in a week, with attacks of severe pain in the epigastrium accompanied by a chill and followed immediately by fever and sweat, and in a few days by jaundice. He died several months afterwards in the writer's care, of obstructive jaundice from impacted calculus, after two of these attacks in succession.

When these attacks occurred every day or every second day, it can be readily seen how a mistake in diagnosis could have been made. Attention to details, however, with the therapeutic test, would have been good aid. The paroxysms, by the way, were no doubt due to the irritation of the discharging calculus. The other case was that of an impacted, possibly ulcerating biliary calculus. The history of the case, the jaundice, and the local inflammatory changes, prevented one from erring.

In addition to the preceding examples of paroxysmal fever, a series of cases will be adverted to which Murchison has not referred to in his lectures, and with the nature of which it is of the utmost importance to be perfectly familiar. Reference is made to catarrhal inflammations of pulmonary, the gastro-intestinal, and the genito-urinary mucous membranes, with secondary intermitting fever resulting therefrom. Especially important is it, for unless the fever is traced to its source, grave organic mischief will become so pronounced as to lead to disastrous consequences. Witness a phthisis following an overlooked bronchial catarrh.

It savors much of the teachings of Broussais, to say that catarrhs are the source of fevers; but there is no doubt that just so far as the philosophic Frenchman erred in that extreme, so do we at the present day err in the other, by attributing most fevers to a zymotic process. Prof. Pepper,* in a timely and instructive address, calls attention to these dangers: That fever is too often considered as due to a zymosis; that zymotic diseases are of self-limited duration; hence that active treatment is of no avail, and especially that the accompanying catarrhs are neglected. Further, on account of these beliefs, the catarrhal process that is often the cause of a fever is overlooked, and thus the commencement of serious local disease is not thwarted.

Reference was made, in another portion of the paper, to the frequency of assuming early tuber-

* On some of the relations of catarrhal affections. Trans. Am. Med. Assoc., 1881.

cular disease of the lung accompanied by intermitting fever, to be due to a miasmatic fever. The following notes illustrate the clinical course of some cases of catarrhal disease of the air passages, which often are the forerunner of so-called catarrhal phthisis. Other examples have been noted, in which here have been only slight catarrhs, without hemorrhage, much cough or emaciation, with attendant fever, occurring in paroxysms.

One of the most typical cases of paroxysmal catarrhal fever came under observation in August, 1880, and was the first to lead to the investigation of this question.

A man, forty years old, of previous good health and habits, of good family history, and residing in a healthy neighborhood, sought advice for "chills." Daily, at 11 a. m., he would have a chill, followed by fever and sweat. The entire paroxysm continued until 6 p. m. His digestion was impaired, and his bowels were constipated. The usual treatment was employed. He reported twice that the chills had ceased to return at once when the medicine was finished. He also reported that his sweats continued throughout the night, and that he was losing flesh and strength. At the third visit, he was much dissatisfied, for a former slight cough had grown more pronounced, he had bloody mucous expectoration, and the chills continued. Upon careful examination, a distinct area of consolidation at the root of the right lung with attending blowing breathing, and some sub-crepitant râles, were found. Active treatment was determined upon, and in six weeks the patient was cured. He has followed his occupation ever since (engineer), is heavier than he ever was, and in perfect health.

Further: A young miss of twenty years, the past winter, was conducted through an attack similar in many respects. Originating in a severe cold, with harassing cough, chest pain, no expectoration and with loss of appetite, nausea and constipation; she lost flesh, and had, the first two weeks of her illness, daily morning chilliness, fever in the afternoon (102°), followed by an exhaustive sweat. During this time the physical signs of a bronchitis were present, with marked localization of the inflammatory process at the right apex. A day of undue exposure and exertion was followed by a severe chill and rapid rise in temperature, with distinct evidence of catarrhal pneumonia at the location indicated above. Chills and fever daily, profuse sweats, emaciation and gastric derangement, were prominent for two weeks. The former symptoms then subsided, but

it was fully two months before the lung cleared up, and the patient gained flesh and strength. The family and friends constantly reiterated their opinion that the attack was primarily malarial.

Probably the most difficult, the most occult form of paroxysmal fever of catarrhal origin to recognize, is the one due to that lesion of the intestinal tract. There are no physical signs to betray it, and generally the intestinal derangement is considered secondary to the febrile process. It seems impossible to distinguish the specific from the catarrhal form, save by the presence or absence of the enlarged spleen, the change in the urine of malarial subjects and of the blood when the malaria is chronic, especially when a recent writer tells us that epigastric pain, vomiting and constipation, are symptomatic of malaria in children. The following record is a typical illustration of this variety, and is a most instructive and pertinent case:

E. M., æt. 5. Inherits a tubercular diathesis from mother. During November and December of 1881, had no appetite, was obstinately constipated, and lost flesh. She became delicate and puny-looking. The latter part of December she was seen on account of the above symptoms and of an irregular fever. The course of the fever was at first difficult to determine, but finally it was found to be distinctly intermittent. She was visited at various hours of the day, and found that at 11 a. m., daily, she would be cold, shivering, and begging for extra covering. Her extremities, nose and ears would be very cold, her lips bluish, and the features pinched. At the same time the pulse would be rapid and the temperature in the mouth 102°. In a half hour the exterior warmed, and very soon she would have high fever, the temperature rising to 103°-103½°. The febrile stage lasted three or four hours, and was not followed by profuse perspiration. Save being weak and without appetite, by night she would be perfectly well. Quinia was given in continuous doses at first, afterwards in doses to anticipate the paroxysm; but without any good effect. The paroxysms were lessened in severity only, while the already poor appetite was made poorer and the digestion more impaired; for two weeks an anti-periodic treatment was continued, and at the same time laxatives were used to overcome the constipation; at this time (January, 1882,) she was thin and worn, the paroxysms of fever were daily, the appetite was very poor, the breath offensive, the tongue covered on the dorsum with a yellow-white fur, pointed, and with no papillæ; vomiting occasionally occurred, and always some pain after eating;

the bowels remained obstinately constipated. It seemed to me, after a time, the fever was a secondary matter; that the gastro-intestinal disorder was primary, and that such disorder was subordinate to the diathetic constitution. Hence she was placed on small doses ($\frac{1}{8}$ gr.) calomel with bicarb. of soda (5 grs.) every three hours. In three days cod-liver oil with syrup of the hypophosphite of lime was added to the treatment. At once she began to improve; her appetite first, then her bowels, became more regular. In two weeks the child rapidly improved under this treatment, after being treated previously for more than two weeks for malaria. It may be added here that twice or three times E. became constipated with similar febrile symptoms noted above, and that the parents, without my advice, cured her with the cod-liver oil mixture.

A case very similar to the above was also seen. It is useless to report the details of the case; remedies directed to the gastro-intestinal catarrh, with accompanying intermitting fever, effected the cure.

A case of stricture of the pylorus, in its course, at one time presented daily chills and fever. Quinia did not control the paroxysms. During the time of the fever, and for a week afterwards, the stools of the patient were composed of mucous or membranous casts of the intestinal canal, or of a pultaceous mucoid discharge.

These cases incontestably prove the proposition that intermittent fever is often due to catarrhal inflammation of the intestines, and that remedies directed to this locality alone will cure the disease.

This clinical record will be closed by the report of an observation of a case, the nature of which is somewhat obscure. It is not given, therefore, without some misgiving. It appears that the only title that could be applied to it would be paroxysmal fever of neurotic or hysteroidal origin.

The patient was twenty-five years old, of a rheumatic diathesis and nervous temperament. She presented a history of "chills and fever," recurring at irregular intervals for two years. The paroxysms were of the quotidian type and the attacks lasted one or two weeks. Considered to be malarious; quinia or cinchona was always given by her attendant, and the usual remedies for malarial toxæmia used, without cutting short or preventing the attacks. The writer attended her through two attacks. They were of the following nature: Preceded by dyspeptic symptoms for a few days, a violent chill attended the onset of the attack, accompanied by severe headache, with tender spots, and one or more localized points of

pain in the body. In one of the attacks the pain with the first chill was fixed at the end of the spine with exquisite tenderness; in another, it was in the epigastrium. The chill was an hour in length, and followed by fever. With the fever the face would flush, the eyes "burn," and the skin be hot and dry. The temperature would rise to 103° or more, the pulse be full, bounding, rapid. Evidences of gastric catarrh, with constipation, were also noted. During the paroxysm, the most pronounced emotional disturbances were manifest, so that had fever been absent it would have been without difficulty considered a case of hysteria. A sweating stage of two hours followed the fever.

The paroxysms recurred daily for a week, but with the repetition of each one the pain would be seated in another portion of the body—in the occiput, the shoulder, or the knee-joints—while the emotional disturbances would be also present. The pain was described as unbearable, and could not be influenced by almost incredible doses of the usual anodynes. Quinia was given in enormous doses in the first attack, without any beneficial influence.

The fact that the paroxysms occurred towards night, and that they were accompanied by hysterical symptoms of a high degree, the inutility of quinia and the absence of enlarged spleen, rendered the opinion that the case was of neurotic origin, probable.

The second attack was very similar. Vomiting was, however, a more persistent symptom. The duration was about one week, and it appeared to yield to remedies addressed to the hysteria and the gastric irritability. The whole tenor of the patient's life has changed since then, so that for two years she has not had a return of the supposed malaria, notwithstanding she is exposed to the same malarious influences.

Time will not permit a review of the various affections in detail, in order to establish a differential diagnosis between these simulative disorders and a true intermittent. Any attempt at a positive diagnosis of paroxysmal fever, however, should not be made without keeping in mind the following proposition: In the first place, one would say that given a case with a chill and fever, a diagnosis of intermittent ought not be made from the nature of the first paroxysm, unless it be vital to do so, as in a pernicious intermittent. Then, if such a case is presented that yields but partially to anti-periodics, they should be discontinued and a fresh start in the diagnostic inquiry taken.

In order to fully establish a diagnosis, a careful study of the antecedents of the patient should be made relative to previous health, habits, place of residence, and family history. Then, in favor of malarious intermittent, we should, after this study, expect a morning hour for the chill (Flint), the well-known changes in the composition of the urine, and if chronic, the enlarged spleen and the pigment granules in the blood. If with one or more of these favorable factors present we could exclude all possible source of organic disease, by an examination of each individual organ, the blood (leukæmia), the eye ground (tuberculosis), the lungs, liver, and gastro-intestinal tract, we would be warranted in the diagnosis of malarial intermittent.

It seems, further, to be of value to note that emaciation of a high degree is more common in non-malarious intermittents.

The same may be said of exhaustion. The latter occurs to a certain degree, and is attended with a pronounced anæmia, so easily recognized as of malarial origin. Then, too, a long sweating stage and a low febrile range rather disprove the presence of the malarious influence.

Enlargement of the spleen is not to be considered, in acute intermittents, as of little moment. In a series of twelve cases of intermittent in children, eight presented the enlargement, which had subsided a year after the first examination.

There is but little doubt that fever is of neurotic origin, and the examples which have been recorded to-night more aptly illustrate this cause than any other class of cases. The profession is so thoroughly imbued, however, with the idea of no fever, unless a zymosis or blood-poisoning, that it is of practical value to refer to the mechanism of fever briefly. As shown by others, disastrous results oftentimes ensue by addressing means to the cure of a zymosis, or by passively allowing a febrile process to continue its supposed self-limited course, when actually a zymosis was not present, and remedies otherwise applied would have been beneficial. The reference to the mechanism, therefore, is to show that often fever is of a reflex origin due to peripheral irritation—a neurosis.

The element of intermittency itself is a powerful argument in favor of its neurosial origin. This is not the time to engage in philosophical speculation, or to demonstrate the relation of the fundamental principle of the rhythm of motion so grandly elaborated by Spencer; suffice it to say that to no other set of tissues or systems could we look to but the nervous system for an explanation of intermittency. Aside from this,

however, in the masterly study in morbid and normal physiology by Wood, on the mechanism of fever, we find sufficient argument and proof "that a depressing poison or a depressing peripheral irritation acting upon the nervous system which regulates the production and dissipation of animal heat," causes fever.

Among the illustrations presented to night, there are some which strongly indicate the reflex origin of fever from peripheral irritation; witness the case of vesical calculus or of gall-stone. By what other supposition could the phenomena be explained? Likewise, though with an element of doubt intermingled, in the cases of gastro-intestinal catarrh, the fever may be considered as due to reflex processes. In the other cases, the fever is, no doubt, due to the absorption of a poison which acts upon the nervous system; and as opposed to Charcot and Billroth, one would think that the phenomena of intermittency are due not to paroxysmal discharges of pus or poison into the blood, but to rhythmical responses of the nervous system to a constantly-acting poisoned blood.

3705 Powelton Avenue.

NOTE ON A SPECIMEN OF INTRA-CAPSULAR FRACTURE OF FEMUR WITHOUT UNION.*

BY HENRY LEAMAN, M. D.,
Of Philadelphia.

Mrs. Mary A. Nugent, aged sixty years, fell, January 23, 1884, while attending her household duties. Was not dizzy at the time.

I saw her first January 24, 1881; she was then lying on a settee, but was unable to stand or move about. On examination, from the preternatural mobility intra-capsular fracture was diagnosed. My attendance was continued at intervals during the months of February, March, April, and May. She was unable to help herself in any way; by help she could be gotten on a Charleston chair, and this was the only treatment attempted. The most of her pain was in the adductors; there were shortening and eversion of toe.

She continued in the same room and on the same settee and chair until I was called to see her, January 6, 1884, when I found her dying from exhaustion. She died January 8, 1884. Privilege was granted to examine the hip. The specimen here presented was obtained. The acetabular cavity was normal in appearance. The

*Read before the Philadelphia County Medical Society, March 19, 1884.

head of the femur lay in the cavity free. The socket and head of the bone were covered over with a membrane, firm but somewhat incomplete. Upon this surface the upper extremity of the femur had formed an artificial joint, the neck having been absorbed. In the surrounding tissue on the inner side was a fragment of bone one and one-half inches long.

This case has no special interest, except, perhaps, in the fact that the head had undergone fatty degeneration, and that the patient made so little progress towards locomotion, never being able to walk on crutches. Doubtless degeneration in other parts of the body caused her death. But no further post-mortem was granted.

HOSPITAL REPORTS.

NEW YORK HOSPITAL.

CLINIC OF PROF. WILLIAM H. DRAPER.

Reported by W. H. SEELYE, A. M., M. D.

Iodism and Zoster.

(GENTLEMEN: This is the patient whom you saw some time ago suffering from an iodic acne and eczema of the legs (see page 523). He came into the hospital with the lesions of constitutional syphilis, for which he was successfully treated by the mixed treatment; and after the disappearance of the syphilitic lesions, the treatment with iodide of potash was continued, until the specific physiological effects of the drug manifested themselves in the production of a cutaneous eruption. And I called your attention at that time to the fact that this was an illustration of the effect which iodine sometimes has upon the nutrition of the skin. He has been here ever since that time. Though he got well of the eczema upon the withdrawal of the iodine, yet he remained here because of a furunculosis, which seems to have been another consequence of the iodism.

Last Saturday night, about five days ago, my attention was called to him, and I found him suffering intensely from a neuralgia, which he referred to the lower part of the right side of the chest, and to the upper abdominal region. I found no lesion in the chest or abdomen to account for the pain, and so I looked upon it as a simple neuralgia, and gave him morphia to relieve it. The pain recurred on Sunday, and so in addition to the morphia to relieve the neuralgia, applications of poultices and turpentine were made to the skin, for the purpose of exciting counter-irritation. On Monday night I found that the amount of counter-irritation produced was in excess of what had been expected from the remedies, and so they were withdrawn. On Tuesday night I observed groups of vesicles over this region, which appeared more distinct than they are now, though they were partly concealed by the hyperæmic condition of the skin. And at the same time the pain was so severe, as to cause him to scream out when touched.

Yesterday it was less so, but still large quanti-

ties of opium were necessary to make him comfortable. The pains were of the characteristic neuralgic character, were sharp, shooting, or lancinating, and were aggravated by movement or by taking a long breath; so he held the right side of his chest almost perfectly still in breathing. Yet there was no sign of any lesion in the chest or abdomen. The neuralgia was in fact in the skin; and it is a neuralgia of the lower dorsal and upper lumbar nerves. This remarkable effect of counter-irritation is one that is sometimes observed, and especially in that form of neuralgia of the trunk and extremities which is attended by a vesicular eruption, and which is called herpes zoster. The eruption is vulgarly called "shingles," from a corruption of the Latin word "singula," meaning a belt or girdle; and it is so named from the fact that the eruption sometimes forms a partial girdle around the body. But this does not often happen. Zoster is usually unilateral, but it occasionally occurs upon both sides, and in such cases the extremities may so nearly approach one another as to form a nearly complete girdle. It was said formerly that if the eruption was upon both sides, it was always a fatal disorder. But it is doubtful if by itself, alone and uncomplicated, it is ever fatal. It is a very painful, but as a rule, I think, a very benign disease. It is one of the most satisfactory illustrations of the trophic disturbances of the skin, which sometimes occur along with disturbances of the sensitive nerves, which we have. The cause of this disease is not well understood, some thinking that it is due to peripheric irritation, and others that it is the result of some central irritation. But that it is due to an irritation and congestion of the roots of the spinal nerves is, I think, the most generally adopted belief of the present day. This neuralgia may occur in many localities, such as in the head and in the branches of the fifth nerve in all three of its distributions, and also in the distribution of the cervical nerves to the neck and shoulders, and lower part of the scalp, and also in the trunk and limbs. Pain is the prominent symptom at first, and is what especially attracts attention. It is sometimes only of moderate severity, and this is the rule particularly in the young. In them and in healthy adults it is not apt to be very severe. But after middle life, and especially in old and feeble people, it is one of the severest kinds of neuralgia that you will ever meet with. But the neuralgia itself does not always disappear after the eruption has disappeared; and even after every trace of the local disturbance has gone, the administration of opium is sometimes needed. The eruption is therefore only an incident of the disease, and not an essential of it; but the lesion itself is in the roots of the spinal nerves, and so the pain may persist long after the trophic disturbance of the skin has entirely subsided. Locally all trace of eruption is apt to subside, in a young and vigorous patient, within a week or ten days; but in the old, and in feeble persons past middle life, it is not always so simple an affair. For in such patients I have seen the vesicles become filled with a sanious fluid which underwent decomposition, and thus the parts affected became the seat of a gangrenous inflammation. But this is liable to occur only in debilitated and broken-down pa-

tients, and you do not expect it in healthy adults. But the greatest suffering is from the neuralgia, which may precede the eruption, and continue while it lasts, and persist for weeks or months after it has disappeared. This case is not a good illustration of zoster as you usually see it: for here we have in addition another dermal lesion, from the application of a vesicant to the skin, which obscures the proper lesion of the zoster. The disease is now subsiding, and the man is suffering less pain.

In regard to the treatment of this malady, I regret to be obliged to say that it is for the most part palliative, and I do not know as you can do much except to relieve the pain. Quinine and opium, and all the measures which you would adopt in the treatment of any other case of neuralgia, should be tried. Occasionally I have seen belladonna to the skin seem to do some good; but I do not know that it does, because where I have used it, it has been in connection with opium or other anodynes. On the theory that this disease depends upon a congestion, or an inflammatory condition of the roots of the spinal nerves, it has been suggested that the pain might be relieved by the application of the thermo-cautery along the spinal column. And if this man's neuralgia continues, I shall advise such an application here. I have never tried it yet, for it is a comparatively recent suggestion, so I know nothing as to its efficiency. But in cases like this, where medicines seem of little use, I think it is best to try any new method of treatment which offers any hope of success.

Cardiac Palpitation.

The next patient is a woman, 44 years of age, born in Ireland, a widow, and was admitted to the hospital November 24. There is nothing of importance in her family history. She has had three children, all of whom are dead. One died in utero, and the last one died three and a half years ago. Seven months before admission her menstruation ceased, but it returned after a time; and then it stopped again, and she has not menstruated for the past four months. She has been subject to occasional weak spells. Six or seven years ago, she had an attack of rheumatism in the foot, which lasted two months. She does not use alcohol in any form. Four months before admission she was taken ill, and she was told that she had kidney disease. She complained of pain in the back and hips, of cardiac palpitations and a sense of oppression in the chest, and of attacks of vertigo and ringing in the ears, of floating specks before the eyes, and of a slight cough. These symptoms have been constantly increasing. Her bowels and micturition have been normal. On admission her pulse was 96, respiration 22, and temperature 101°. Her urine was amber-colored, of an acid reaction, of a specific gravity of 1.020, and it contained a slight trace of albumen, and a few leucocytes, but no casts.

Gentlemen, I want you to observe the charts which contain the record of the vital signs in this case, from the time of her admission until now; because this is a good illustration of a disorder which you will meet with almost every day of your life, and with which you will at times be much puzzled. The most striking feature of this record is the extreme frequency and

irregularity of the pulse. And most of the symptoms can be explained by the great irregularity in the circulation and distribution of the blood, which this sort of heart action necessitates. Cardiac palpitation is a very common disorder, and it is sometimes only a transient symptom, which disappears with the cause. And this may be indigestion, great emotion, excitement, anger, grief, or sudden loss; and when the cause, whatever it is, passes away, ordinarily this disturbance of function disappears also. It is not always, however, a transient phenomenon, but it is sometimes a persistent one, and the source of great distress. And these cases of persistent palpitation I have observed under a great variety of circumstances. I have noticed that this persistent irregularity of the heart may come from a great nervous shock. For example, I have known it to occur in men who from a condition of affluence had suddenly become paupers. Or it may be the result of great grief or a sudden fright, and these emotional disturbances are sometimes the cause of persistent as well as transient palpitation. And you should bear this fact in mind. Age will have an influence over the occurrence of this persistent palpitation, and sometimes it is connected with that critical period in a woman's life which is known as the menopause; and I have seen a considerable number of such cases. In fact at the period of menopause you are very apt to have in many women marked disturbances of the circulation, and this manifests itself in irregular action of the heart, and in transient congestions which are evidenced by sudden flushings of the face, dizziness, tinnitus aurium, *muscae volitantes*, and hallucinations of sight and hearing. These cases are sometimes associated with that particular form of palpitation which was long ago described by Graves and also by Basedow at about the same time, in which you have also a disturbance in the circulation of the thyroid gland, and in the loose connective tissue just behind the eyeballs. This triad of symptoms was so frequently found together by them, that they looked upon this association as constituting a special form of disease, and so in honor of them it was named Basedow's or Graves' disease.

Now, it is a mistake to suppose that this association of symptoms is essential to Graves' disease, and Basedow's disease, for the essential element is the disturbance in the blood and circulation, which is manifested by this extreme frequency and irregularity of the heart. The enlargement of the thyroid gland is a frequent but not a constant symptom, and the same is true of the exophthalmic enlargement. For there may be an irregular action of the heart accompanied by an enlarged thyroid gland, but with no exophthalmos; or there may be exophthalmos and no thyroid enlargement; or both may be absent and the disturbance of the cardiac circulation may be the only evidence of the disease. Or if both the thyroid enlargement and exophthalmos have been present, one may disappear for a time, while the other persists.

Now, I have mentioned emotional disturbances and the menopause as the common causes of this condition; but they are not the only ones. It would seem sometimes as if this derangement of the nervous energies which control the circulation

occurred in connection with simple anæmia in men and women both. And it also sometimes occurs in connection with organic heart diseases, but this is not essential to its occurrence. But as a result of this increased frequency of the heart's action, you do frequently get a cardiac hypertrophy.

Now, here is a woman 41 years of age, who is evidently passing through the menopause, and this disturbance of the circulation has occurred to some extent in her. When she came in she had this extreme irregularity of the pulse and respiration which you have seen, and some enlargement of the thyroid, and a slight degree of exophthalmos. She has had besides what is occasionally observed in this disease, namely, a slight degree of fever. Her temperature has been above the normal ever since she came in, and at times it has been pretty high. Thus, yesterday, at one time it was 104.5°C, and with this there was a very rapid and feeble pulse, and a frequent and irregular respiration. With her, therefore, the cause of these disturbances seems to be permanent, and not yet under the control of any remedy that has been used. You may ask what is the cause of these disturbances in the vital signs? And I answer, that I do not know. It has been thought by some that it is a disease of the sympathetic system; and careful explorations have been made in the sympathetic system of nerves, in order to find out this cause. And experiments have been made by making lesions in the sympathetic nerves, in order to see if these symptoms can thus be reproduced in animals. In a few cases lesions in the cervical sympathetic are said to have been found post-mortem. It seems probable that the lesion is either one of the central nervous system, or of the sympathetic system; for the disease often occurs in purely nervous subjects, and it also is frequently found in women at that period of life when nervous derangements are most apt to occur, the menopause. But exactly what the nature of the lesion is, is not known.

The prognosis in a fair proportion of cases is good. At all events, some get perfectly well. But some get pretty well and then relapse again, and a few do not recover at all. When associated with organic cardiac affections, you of course cannot expect a perfect recovery, and in pure and simple Graves' disease you do not look for it.

In the treatment of this disorder, the most important element is rest. Putting the patient to bed is a most useful expedient in all forms of palpitation. You know that in a state of health there is a difference of fifteen or twenty beats a minute between the pulse-rate of a person in the erect and in the reclining posture. And this difference is not due simply to the muscular effort put forth in retaining the erect posture; for this same variation of the pulse with the change of posture has been observed in the case of a man who was strapped to a board in such a way that no muscular effort was required for him to maintain the erect position. It is therefore important in all cases to give the patient the advantages of the recumbent position. Some effect seems to be thus produced in the cerebral circulation, which results in increasing the inhibitory action of the pneumogastriæ.

The next important indication for the treatment

is to remove the cause of the disturbance. When it occurs as the result of shock, you cannot do anything to remove the cause. But if the cause is connected with the menopause, you may do something here to give relief, by the use of such remedies as will equalize and regulate the circulation. Digitalis is of very great service for this purpose, and Trousseau even went so far as to say that digitalis is a specific for this disease; but this is not quite true. I have sometimes thought that strychnia was of some benefit. In cases with anæmia, iron in combination with digitalis is of great service. But the great point is to keep the patient at rest in the recumbent posture, and to feed him carefully, so as not to aggravate his sufferings by adding indigestion to his other ailments. And then you should give your attention to regulating the circulation and to the administration of nerve tonics and iron, and if possible to the procuring of refreshing sleep. These are the broad principles of treatment, which are sometimes attended with success and sometimes not. I have known the iodide of potassium to relieve a severe case of palpitation in a lady who came to me for treatment. And it is a remarkable fact in this connection that Trousseau says that under no circumstances is iodine to be used in this malady. I must admit, however, that I have never seen the iodide of potassium do as much good in any similar case since; and I am even in some doubt whether the iodide had anything to do with the improvement in her case; but I am not sure that it did not. I will mention as a curious fact in this connection that the same lady was relieved at another time of a persistent chronic bronchitis by the use of potassium iodide. So perhaps with her this remedy is a specific for many other disorders, as well as those of the circulation. It has not done any good here, nor has digitalis or iron. There is a persistence of the symptoms here which has thus far resisted the influence of all drugs. We can only try to relieve her now by the use of stimulants, and morphia with quinine.

MEDICAL SOCIETIES.

PHILADELPHIA NEUROLOGICAL SOCIETY.

The first stated meeting was held Monday evening, February 25, 1884, the Vice-President, Dr. Charles K. Mills, in the chair. Dr. Mills read a paper on "The McGinnis Case."

A history of the case, including an account of the crime, and a discussion of the formation, proceedings and reports of the commission to inquire into the mental state of McGinnis, was given.

The facts indicating the insanity of McGinnis were summarized by Dr. Mills, in the course of his paper, as follows: A bad family history; evidences of the monomaniacal character, as shown by a study of his life and present condition; the existence of a delusional state, and even of special delusions of a depressive and persecutory type; the presence of hallucinations of hearing and sight, the former being connected largely with persecutive ideas; some manifestations of religious monomania; a history of alcoholism, and the fact that his chief delusion, that of marital infidelity,

was one often found in chronic alcoholic insanity.

The next paper was entitled "Case of Unilateral Spasm, Hemiplegia, and Aphasia, Following Measles in a Child Two Years and Four Months Old," by Lambert Ott, M. D., Assistant in the Nervous Department of the Post-Graduate Course of the Jefferson Medical College.

Boy, aged two years and four months, healthy and intelligent, talked well for one of his years. April 2, he had a mild attack of mumps. Seven days later, he was seized with premonitory symptoms which ushered in a well-defined attack of measles. Other children in the same house were just convalescing from this exanthema. No physician was called, and nothing more was done than keeping him warm in bed and administering an occasional purgative. On the tenth day after the beginning of the disease, the mother states that he felt well, was laughing and playing in bed, but instead of the dull yellowish stains which remain after papules of measles have faded, his skin was dotted with spots of a purplish hue. The same morning the mother noticed a twitching of the muscles of the right eye and right side of face, and soon after similar movements of the right arm and leg. He remained conscious during the spasm, but was unable to speak, motioning for anything he wanted. After the spasm had existed an hour, the leg ceased to move, and was found to be paralyzed. Half an hour later the arm-jerk stopped, and the limb lay powerless by its side; the face movements continued only a few minutes after the arm became quiet, when the side of face was observed to be paralyzed. While the right-sided convulsive seizure was going on, the left arm and leg were affected with choreic movements, which subsided soon after right-sided paralysis was manifest. Two hours after the first appearance of the spasm, I noted the following condition: Ptosis of right eye; no change in pupils, and no disturbance in movements of eye-balls. When he cried the right side of the forehead remained smooth, while the left was markedly corrugated; no paralysis of tongue, but complete *aphasia*. I was unable to investigate the special senses, on account of the age of the child. Motion in the right arm and leg was completely paralyzed, sensation partially. He was conscious, and drank water with very little difficulty. The left side of the body showed no disturbance of sensation or motion, excepting occasional choreic twitching. The dread the child had of strangers prevented me from examining the heart. Temperature, 101°C; pulse, 120; respiration, 20, and very irregular. Some bronchial catarrh.

Second day. Temperature 102, pulse 130, respiration 40. Had no vomiting; intelligence remained good; tongue dry; passed water and feces involuntarily. During the next six days his fever remained high, cough increased, and evidences of catarrhal pneumonia developed.

About the ninth day the mother called my attention to a bulging of the right side of the chest, resembling the deformity produced by a large pleuritic effusion, with a marked lateral curvature of the spine, the convexity being toward the right side; percussion of the lung of this side elicited hyper-resonance, and auscultation, normal breathing with prolonged expiration. The chest deformity was apparently due to contraction of

the muscles of the left side. He had conjunctivitis of right eye, and dribbling of saliva from the right angle of the mouth. Was very irritable, and often carried his hand to his head and moaned. Urine examined and found normal. The choreic movements of left side returned, but were not as marked as at first.

In the second week the muscles of the face began to regain power.

In the third week there were no marked changes in his condition, except a peculiar swelling and tenseness of the paralyzed leg, which persisted four days, and suddenly disappeared during one night; the next morning the leg was very flabby. Electro-muscular contractility was fair. In the latter part of the third week his head was drawn to the paralyzed side, the chin pointing to the left, showing the peculiar influence of the healthy sterno-mastoid and other neck muscles, which was pointed out to me by Dr. Eskridge. The muscles of the right side of the neck were flabby; those of the left side were hard and tense. Lifting the head would place it erect, but when unsupported, would fall into its former position. In the fourth week movements were noticed in the arm, and in the fifth week the leg began to regain power. He was now, for the first time, using a few monosyllables, as *ma*, *pa*, etc.

In the fourth month he walked fairly; used a few more words, especially the simpler ones.

In the sixth month of his disease his general health was good, and he was talking more, but only using such familiar words as children learning to speak usually employ. His gait was fair and he was able to run, but there existed a marked weakness of the flexor and extensor muscles of the anterior part of the right leg, and of the extensor muscles of the right arm.

I look upon the case as one of embolism of the left middle cerebral artery, obstructing the first branch, called the frontal-external and inferior, which supplies the third frontal convolution (convolution of Broca) wherein resides the centre of speech; also the second and third branches, called respectively the anterior parietal of Duret, or the artery of the ascending frontal convolution of Charcot, and the posterior parietal artery, or the artery of the ascending parietal convolution of Charcot. These two latter branches supply the motor centres of the extremities (Ferrier). The fourth branch, which supplies the angular gyrus, was probably not obstructed, as vision remained apparently unimpaired.

The motor centre of the facial muscles occupies a region in close proximity to those of the extremities, which is also supplied by branches of the middle cerebral artery.

There are some marked peculiarities in the case.

First. The age of the patient, two years and four months.

Second. There was no loss of consciousness, which Hamilton says is the exception. In most cases there is either partial or complete loss of consciousness.

Third. The disturbance of conformity of the chest, on the ninth day after the spasm.

Fourth. The falling of the head to the paralyzed side twenty days after the spasm.

Whenever he had a good night's rest, he was

able to hold his head erect for two hours; after that time it lay to one side.

The order of recovery of the paralyzed parts was as follows: First, it is well to recall that the lower extremity lost power first, next the upper extremity, then the face, and later the neck and chest. In order of recovery, the face, neck, and chest showed the first signs simultaneously, then the upper extremity, and next the lower extremity. When considerable power had been regained, quite noticeable yet was the weakness of the extensor muscles of the forearm, which gave the hand the peculiar position that resembles the wrist-drop of lead palsy.

Most interesting of all was the occurrence of aphasia. Here was an active little boy, twenty-eight months old, who talked connectedly and as well as usual for one of his age, is suddenly stricken with unilateral spasm, followed by hemiplegia and total loss of the power of speech. His intelligence did not wane one whit during the whole trouble. When thirsty, he protruded his tongue against the upper lip. If the parents told him the doctor was coming, he immediately manifested great fear, and beckoned for his mother to come near him.

If he wanted some article in a distant corner of the room, he pointed his finger at it and began to whine. When they put their hands on the wrong article, he intensified his whine, by which they understood it was not what he wanted. As soon as they touched the desired object, a smile came over his countenance.

In the fifth week he spoke his first words, as "pa," "ma," and "no." Later, other simple words were added to his vocabulary. The mother, a woman of experience, having had eight children, made a remark which struck me very forcibly, that it seemed to me as if he had to learn to talk over again. At no time did he misapply a word, as calling a "chair" a "table." When once he knew a word and its application, he always used it afterward. At this date (nine months after the attack) his speech is disconnected. If he desires to express a thought, he can make a good beginning, but is unable to finish. For instance, he wants to use the sentence, "Katie, get my hat in the other room!" he can only say, "Katie, get my hat ——" for the rest of the sentence he uses signs. His being unable to finish a sentence is not that he did not know the word "room," for when used otherwise he had no trouble in recalling it. When he used three or four words in succession, his speech powers seemed at an end.

The discussion on Dr. Ott's paper was opened by Dr. Francis Dercum, who said he was inclined to regard the interesting case reported by Dr. Ott, as more likely to be one of hemorrhage than of embolism. It is well known that the miliary aneurisms described by Charcot and others, occur sometimes in the very young, therefore, one of the conditions which leads to hemorrhage may be present in infancy. The absence of valvular disease of the heart was also against the idea of embolism.

Dr. Dercum thought that the symptoms presented by the case indicated a lesion of the internal capsule and basal ganglia, rather than of the convolutions. He referred to the more frequent occurrence of hemorrhage in this region, and

also of the wide extent of cortex that would have been required to be involved in order to explain the phenomena.

Dr. Charles K. Mills agreed with Dr. Dercum that, from the history of the case, the absence of recognized heart lesions, and the age of the patient, the case was probably one of hemorrhage. He believed, however, that some of the facts indicated a cortical lesion. One of these was the existence of choreic movements on the side opposite that which was paralyzed.

According to Duret, when irritative lesions of the cortex occur, they produce not only spasm on the opposite side of the body, but also may cause contraction or spasm on the same side, the result being brought about through irritation of the sensory nerves of the dura mater, which irritation is conveyed to the bulbo-medullary centres.

Dr. Mills referred to the completeness of the paralysis, as a matter of great interest in connection with the views of Broadbent as to the communication of well-worn commissural channels of those parts of the central nervous system which preside over movements of the two sides of the body which are associated.

Dr. James Hendrie Lloyd referred to the remarks which Dr. Ott had made about the angular gyrus not having been involved, and said he was not aware that any well reported cases of embolism affecting the angular gyrus and causing blindness had been published.

Dr. Dercum said that the occurrence of choreic movement on the side of the lesion could be as well explained by the transmission of irritation by means of the commissural channels of the brain, as by the views of Duret.

Dr. Ott closed the discussion, and said in favor of embolism is the sudden appearance of the attack, and an array of symptoms which usually follow an embolus in the left middle cerebral artery. In favor of cerebral hemorrhage is the disorganized condition of the blood as a resultant of measles, predisposing to such an occurrence.

On the conclusion of the discussion of Dr. Ott's paper, Dr. Charles K. Mills read a "Note on the Use of Nerve Pressure for the Relief of Hysterical Contracture."

In three cases, Dr. Mills had resorted to strong pressure, applied, by means of the thumb or fingers, to the trunk of the nerve supplying the muscles affected by the spasm in contracture; in a case of hysterical spasmodic torticollis, and in one of hysterical contracture of the wrist and hand, the condition passed away, and remained relieved; in a case of long-standing contracture at the knees under the effects of pressure on the sciatics the spasm disappeared, but recurred. The procedure was simple, and had value, both as a means of diagnosis and treatment. Whether the effect was produced by mental effect, by causing a temporary paresis, or by the pain, he was not prepared to say.

Dr. Wharton Sinkler spoke of having used the method unsuccessfully in a case of facial spasm, which was not, however, hysterical in character.

—M. Gérard Lagüe (*Lyon Med.*) states that syrup of gooseberry will completely disguise the taste of iodide of potash.

EDITORIAL DEPARTMENT.

PERISCOPE.

Large Doses of Calomel in True Croup.

Dr. O. T. Schultz contributes a very interesting paper on this subject to the *American Practitioner* for May, 1884. He first details the method introduced and extolled by Dr. Reiter, of Pittsburgh, Pa., who holds that that this inflammation is due to "too much fibrine in the blood," which condition is produced by the liver having lost its fibrine-destroying power, and that mercury is the specific for compelling the liver to resume this function. Be his theory right or wrong, Dr. Reiter has put it into practice with great boldness, and with astonishing results. And he anchors his faith fully and squarely upon mercury in all forms of pseudo-membranous inflammation—fibrinous, septic, and gangrenous, sthenic and asthenic—and without ever engaging in those delicate subterfuges, steaming, burning, or cutting. His results are reported to be marvelous, and unattended with any unpleasant after-effects, while the boldness with which he pushes mercury makes one's hair stand on end. Dr. Schultz then goes on to relate the case of his own boy, whom he treated according to Dr. R.'s method. He says:

After all the usual remedies had been tried and failed, in my despair I concluded to try Reiter's method. The treatment was begun at 9 a. m. on 13th. The patient was given calomel: twenty grains at 9 a. m., ten grains at 10, five grains each at 11, 12, 1, 2:30, 4:30, 6:30, 8:30, 10:30, 12:30, 2:30, and 5 a. m. of 14th, being *eighty-five grains* in twenty-four hours. No other remedial measure was made use of.

"During this time his condition was as follows: At 12 m. of the 13th he is sleeping quietly, breathing easily; the hard sound in inspiration and expiration is replaced by a soft gurgling or bubbling; the cough is loose; large, loose râles are heard in the larynx; the surface is warmer than normal, soft but not moist; the pulse is very fast and small. At 2 p. m. profuse vomiting; glairy mucus with yellowish flakes; there is one thin, loose, not fetid passage. At 2:30 no more dyspnoea; stridor entirely absent; voice clearer, stronger; cough not frequent, loose, barking. Vomited again at 2:45; water and flakes looking like membrane, bearing occasional clots of blood; a similar vomit at 4, and a thin, loose stool containing flakes of white mucus. At 6 is bright, playful, breathing noiselessly; eats some, which he has not done since yesterday; cough still hoarse, loose; voice clear, possessing some timbre, not much given to creaking. Went to sleep at 8 o'clock, sleeping quietly, breathing normally, without any rattling in larynx or any signs of dyspnoea; no fever; an abundant, dark passage, coming on rather hurriedly at 11. From this on he slept soundly and well till morning, his sleep broken only by occasional barking cough and by taking his medicine. At 7 a. m. of 14th, he had another dark passage; the voice is

clear; cough at times hoarse at times not, loose; respiration easy and noiseless; some feverishness, and pulse is rapid and small. Hydrargyrum bichlorid., one-sixteenth grain, is ordered every two hours; but the second dose causing vomiting in half an hour, the dose is reduced to one thirty-second of a grain. About noon began to complain of frequent attacks of belly-ache. Cough is only at times hoarse, respiration is easy, voice is clear; no appetite, no fever. By 4 p. m. has had two passages; the pain in the abdomen continues, is paroxysmal. In the evening the cough appears drier and is more frequent, and has the characteristics of bronchial cough; small dry râles are heard now for the first time in both lungs. At 10 p. m., hydrargyrum bichlorid., one one-hundredth grain, and ipecac, was begun—a dose every two hours. At night patient slept quietly and well, with scarcely any cough.

"At 7 a. m. of the 15th, somewhat hoarse; appetite better; bright and playful; looks pale and has lost considerable flesh; belly-ache is gone; bowels are normal; cough raw, dry, not hoarse, not severe; mercury and ipecac continued.

"On the 16th, the bronchial catarrh was in resolution; soft, mucous râles had taken the place of the dry sibilant; cough loose, not hoarse; the boy was bright and playful; appetite had fully returned; bowels moved normally. The medication was kept up till the 17th, when there was no further occasion for its continuance.

"Remarks.—The change from 9 to 12 o'clock of the first day was something wonderful. Several hours before vomiting occurred respiration had become easy, and the obstruction in the larynx softened. Patient was lying in a peaceful slumber, the anxious expression of the morning entirely effaced.

"As further proof of the melting away of the exudation, we find a few hours later the voice partly resuming its timbre. Quite a change from the weak, dead, flat sound of the morning. The vomited matter evidently contained portions of membrane. The act of vomiting was a sudden and powerful effort. There was not much gagging, and after the stomach was relieved, quiet was restored. The vomiting was evidently caused by the mercury. There were but six easy feculent passages in the forty-eight hours of the mercurial treatment. There was no straining, but considerable termina set in on the second day, which at once disappeared when the dose of the mercurial was diminished. The bronchitis following upon the croup was evidently equally benefited with the primary disease. The mental hebetude, feverishness, extremely rapid, soft, and small pulse, pale, bloated face, swollen neck, steady increase in the laryngeal symptoms notwithstanding the previous treatment, justify the diagnosis of true croup; and this opinion is confirmed by the flakes of membrane vomited and the course of the disease, corresponding, as it does, in all respects with that described by Dr. Reiter, the originator of this method of treatment."

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

AN OBSTETRIC CASE

(Price, \$15.00),

OR

AN ELECTRIC BATTERY

(Price, \$25.00),

AS PREMIUMS.

Any subscriber to the REPORTER who will send us before the 1st of July the names of *three* new subscribers with their yearly subscriptions (\$15) or *five* new subscribers with \$25.00, will receive, for the three, an Obstetric Case complete, and for the five, an Electric Medical Battery complete. They are new, of the best make, and of guaranteed excellence. The new subscribers will receive the REPORTER *free* from the date of the remittance until July 1st next.

Address DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA, PA.

EXAMINATION OF FOOD AND DRINK.

In every community, and in large cities in every district, so-called "Institutions for the examination of food and drink" will be established after July 1st of this year all over the kingdom of Prussia. The preparations have so far advanced that every one of these institutions will be opened by that time and ready for work.

Each station consists of the district physician, of a veterinary surgeon, and of a chemist. They all have the necessary simple apparatus, of which experience has shown that they are needed for such examinations.

In every province, besides, there exists a central bureau, whose members are recognized authorities in their special branch of study, and where all the more expensive apparatus are kept, which are employed in the more elaborate examinations. Whenever cases come before the local stations needing the most thorough and searching examination, then such cases are transferred to the central bureau. If scientific questions of great importance arise in the central bureau, and a difference of opinion exists between the members constituting the bureau, the matter is referred to the Scientific Deputation in Berlin, as the highest tribunal, and there finally decided.

To guard the local stations against annoyance, nobody can have food or drink examined by them except he pays for it in accordance with a schedule of prices provided for by the Government. Only reports intended for the authorities must be made free of charge; for that purpose the members of the local station receive their salaries. If, for instance, a citizen thinks a certain article of food or drink to have been tampered with, or to be for some reason or other not wholesome or not as represented, the citizen complains to the police authorities or to the district attorney, to the court or to certain other officials. No matter to whom the complaint is at first made, the matter is at once turned over to the police authorities. They prepare a statement, containing the name and residence of the plaintiff, under oath, the name and residence of the person who sold the food or drink respectively, of the manufacturer,

and all the facts of the case. Refusal of anybody to forward, as by law directed, any such accusation of a citizen, or negligence on the side of the police or any other authority in obeying the directions of the law, is punished severely by imprisonment and fine. The police magistrate transmits the statement to the local station, and if they are there able, to decide the question—if they are not, the case passes through the central bureau or the Scientific Deputation, but returns to the local station—they return the statement, accompanied by their report, to the police authorities. Should the charge have been groundless, the matter rests there; but should the adulteration, diseased condition, or decomposition of the food or drink have been proven, the case is transmitted to the public prosecutor, who at once proceeds according to law against the guilty parties, and after judgment has been obtained, the papers are returned to the police authorities, who have to see that by publication in the most widely-read newspapers, and by placards put up in public places or otherwise, the judgment, with a description of the case, finds the utmost promulgation.

In case of epidemics, etc., the examination into their causes, etc., is also made by the local station—or in important cases by the central bureau, or even the Scientific Deputation in Berlin—and the Government is advised as regards the means to be employed for their extinction.

While, therefore, it is made easy to discover and punish adulteration of food and drink, dealers and manufacturers are also protected against wrong and groundless suspicions, as nobody ever discovers anything about the charge which a citizen has made, if the charge itself has not been proven.

A BENEFICIAL LAW.

The following law will go into execution in Germany, July 1 of this year. Wherever more than one thousand mechanics or laborers are living in one locality and are engaged in one trade, as in factories, on railroads, on buildings, or in any other occupation, those engaging and paying them for the labor performed must insist upon the for-

mation of beneficial societies for cases of sickness. The government had tables drawn up by experts, which prove from statistics what contributions for certain purposes are necessary, to guarantee the successful operation and the existence of such societies. If, for instance, one thousand men engaged on railroads—a perilous occupation—combine for the purpose of guaranteeing to each member, in case of sickness, a sum equivalent to his wages received when working, which sums are weekly to be paid for a period of thirteen weeks, and if the society besides binds itself to provide also medical attendance, the amount to be contributed for that purpose by each member amounts to about three cents per week. To these three cents the owner of the factory, or railroad, or the trade organization (necessarily existing, as the law demands it), adds for each member of the society one cent per week, and the same the community must do, in which the society resides.

In communities where such societies do not exist, because the number of persons employed does not reach the height demanded by the law, the community itself must guarantee every mechanic or laborer, no matter how employed, and not belonging to a society of that kind, free medical attendance for a period of thirteen weeks, and an amount weekly, equivalent to the wages received. The necessary money has to be collected from bosses, mechanics, and laborers actually employed, and if not sufficient, by taxation. When a community consists of less than one hundred inhabitants, several such communities must unite for the one purpose. Contracts are made with regular physicians, resident in the locality where their services are needed, and their compensation is fixed by law.

Certainly there is too much of paternal government and encroachment on individual rights in this law for us to hope ever to see it executed in our own country; still its beneficial consequences can scarcely be calculated. Any person earning his bread by manual labor, now has the guarantee in Prussia, that in case of sickness he is certain for a period of thirteen weeks of not only continuing to receive his wages, if his dis-

ease should last so long, but also of free medical attendance. Much misery will be thus relieved and done away with.

NOTES AND COMMENTS.

Paralysis of the Serratus Magnus Alone, without Participation of the Rhomboid Muscles.

An almost unique and very instructive case was recently observed by Ferrier. A heavy bag fell on the right shoulder of a laboring man, who had always enjoyed remarkably good health. Pains and disturbances of motion soon developed themselves in the right arm, and the symptoms were exactly those of paralysis of the serratus muscle. The main interest of the case centered in the fact, that the shoulder-blade assumed that position, which can be met with during rest only when the serratus magnus is paralyzed without the least participation of the rhomboid muscles; the shoulder-blade of the diseased side stood higher and more towards the middle of the back than the left, and the same was the case with the angulus scapulæ. The electric examination of the serratus and its motor nerve demonstrated complete reaction of degeneration, while the rhomboid, the lower part of the cucularis, the levator anguli scapulæ, the infrapinatus, the teretes and the scapular part of the deltoid, evinced for both currents an increased muscular excitability.

Stooping, round shoulders, irregular height of the shoulder-blades, greater prominence of one, etc., etc., all these abnormal positions may be corrected and removed, if the case is not one of too long standing, and if the causing element (as occupation, etc.) can be done away with, by methodical faradization of the muscle or muscles at fault. But we have too often noticed in such cases complete faradization of all the shoulder or back muscles. If we admit that faradization increases the power of a muscle—and this fact cannot be denied—we must see the importance of first discovering the muscle weakened in a given case, and then faradize this muscle alone. The same holds good with manipulation, and with Swedish gymnastics. The motions to be practiced by the latter have all to be made with the one view—of strengthening the weak muscle. It may be that we can thus explain why some manipulators meet with great success, and others with none at all. If, in the case above cited, the serratus alone is faradized, and gymnastics are practiced with only that muscle in view, a cure will be established

within a few weeks, and improvement be at once noticed; while, if the same is done with all the muscles of the shoulder-blade in a case, of that case a cure could take place only by accident, and after a treatment of many months.

Pressure on the Pons by an Aneurism.

In a case in which the post-mortem demonstrated the existence of an aneurisma of the arteria basilaris, compressing the right half of the pons, the clinical picture showed progressing paralysis of the four extremities, specially expressed on the left side. Several days before death the following symptoms were added: Comatose condition, twitchings of the left side of the body, and of the right orbicularis palpebrarum, and frontalis, nystagmus, causing abduction of the bulbi from the median line towards the right, and dyspnœa. But the most interesting phenomenon which Drs. Hallopeau and Giraudeau (*Union Med.*, 27, '84,) observed was the following: As soon as the head of the patient was bent forwards, respiration came to a stop in expiration, the symptom at once disappearing on bringing the head in the opposite position. H. and G. suppose that on bending the head forwards the pressure of the aneurisma on the pons was increased, while on turning the head backwards the tumor was lifted up from the pons and the pressure released. The stand-still of the respiration in expiration is attributed to irritation of the vagus-nodule, for the same phenomenon as in this patient is observed on irritation of the trunk of that nerve. The nystagmus and the deviation caused by it, as well as the twitchings in the right upper facial region, was probably induced by irritation of the origin of the right facialis-abducens.

Peptonuria as a Clinical Symptom.

From a very interesting article written as a thesis for obtaining his diploma by Dr. Fenomenow (Petersburg) and published in the *Deutsch. Med. Zeit.*, 37, '84, we abstract the following important facts:

1. Peptonuria is invariably met with during the final stages of croupous pneumonia, and stands in direct connection with the resorption of the croupous exudation.

2. The presence of pepton in the urine of persons suffering from diffused kidney disease probably depends upon peptonization of the urinary tubule-casts.

3. Peptonuria in phthisis pulmonalis does not

depend upon the extent of the morbid process, but upon the rapidity of its course.

4. In cases of typhoid fever, complicated by constipation, and in cases where the temperature ascends above 40° C. (105° F.), peptonuria is a common appearance.

5. Occasionally, peptonuria is also observed in scarlatina, exudative pleurisy, nephritis, puerperal fever, and in cases of organic disease of the heart, when compensatory hypertrophy ceases.

Diabenzolsulfonic acid is the finest test for peptones in the urine, causing, when peptones are present, at once an orange-yellow discoloration.

Naphtalin in Diarrhœa.

Especially in the diarrhœa of children, naphthalin seems to be an invaluable remedy. Prof. Rossbach, in Jena, has made a series of observations, and discovered that in all catarrhal conditions of the intestines, whether they coexisted with ulcerations or not, also in all inveterate, chronic intestinal affections, and in those of the small intestines as well as in those of the large bowels, provided they did not depend upon organic, incurable diseases, as cancer, etc., naphthalin was a specific, and invariably caused the disappearance of the malady. He never noticed any bad side or after-effect, and most of the naphthalin passed off again by the bowels, while a small percentage of it, changed to phenol, made its appearance in the urine. The usual dose for adults was from eight to ten grains daily. The remedy had also a very favorable influence upon all cases of vesical catarrh, the purulent discharge at once ceasing, and he attributes its beneficial effect in such cases to the changing of naphthalin to phenol in the urine—as phenol, especially in the nascent state, is a very powerful aseptic remedy, at once destroying all micro-organisms with which it comes into contact.

Patients generally do not object to the taste of naphthalin, if it is purified and obtained by sublimation; as a corrigens for its odor, a few drops of bergamot oil can best be recommended. (*Deutsch. Med. Zeit.*, p. 379, 1014.)

Micrococci Causing Loss of Hair.

Without any detectable cause, and without the accompaniment of any other symptom, a male individual was attacked by alopecia, which the patient himself attributed to infection, contracted in a hair-dressing saloon. In the region of the right temporal bone was observed a circular place, 5 to 6 ctm. in diameter, perfectly bald. In its

centre were noticed a few white hairs on the shiny skin, while the margin contained a zone covered by epidermis-scales. In this zone the hairs appeared broken and stunted in their growth. The least pull on a hair at once caused its falling out, the bulb always coming with it. By coloring, Dr. Sehlen, who reports this case in the *Centrbl. f. d. Mediz. Wissensch.*, 15, 1884, was enabled to prove the presence of small, round cocci, which were less than a millimetre in size, and found in large quantities surrounding the hair in the cells of the epidermis, and sprinkled between the sheaths of the roots of the hair. The author has instituted a series of cultures not yet concluded. A mild solution of corrosive sublimate ($\frac{1}{3000}$) destroyed the cocci and established the re-growth of the hair.

Are the Anterior Columns Excitable?

Van Deens first pronounced the view that the anterior columns of the spinal cord are not excitable. Fick proved by his experiments the contrary. But the majority of all investigators was in favor of Van Deens' view. Dr. Mendelssohn has recently tried to solve the disputed question in a different manner from his predecessors. In accordance with the physiology of the posterior columns, the fact is established that motion induced by their irritation is of a reflex character. If, therefore, on irritation of the anterior columns, the motion in the muscles of the extremities produced by it should take place more rapidly, the response to the irritation be quicker, than that ensuing on irritating the posterior columns, we would have the proof that the anterior columns are directly excitable. Mendelssohn's experiments on frogs have really established this important fact. When he irritated the anterior columns of a frog, the motion ensuing in the extremities made its appearance far more quickly than was the case when he irritated the posterior columns. (*Deutsch. Med. Zeit.*, p. 409, 1884.)

Alumen Ustum in Intermittent Fever.

Schidlovsky, a Russian physician of some repute, was the first to employ burnt alum as a remedy in intermittent fever. Lately, another Russian doctor, A. Sawwinsky, in charge of the hospital at Podolsk, near Moscow, has used it in twelve recent cases of the same disease, and with surprising effect. He administered eight grains of the drug twice daily. Even twenty-four grains were easily borne by the stomach, provided a large cupful of water was taken immediately after it.

Drs. Sattikow and Gawrilks, stationed in the Caucasus, reported some time ago that they had also employed this remedy, but utterly without success. Whether it acts only under special conditions, will yet have to be determined, and as Dr. Schidlovsky enjoys a well-merited reputation for veracity, it might be well, considering the present high price of quinine, to try the remedy on a more extended scale, so that we may learn the indications for its use.

SPECIAL REPORT.

OPHTHALMOLOGICAL MISCELLANIES.

BY CHARLES S. TURNBULL, M. D., PH. D.

(Concluded from page 757.)

W. Sykes contributes clinical notes and remarks on a *disease of the eyes peculiar to colliers*.

The sight first fails in bad light, and grows gradually worse, till the pupils are dilated and insensible to light, and only a perception of light remains, while nystagmus is well marked. Recovery takes place on exposure to light and air, without other treatment. The miners attribute the disease to the bad light given by the safety lamp, but Sykes believes it to be toxic, from gases accumulating in the pits.

Sorokin writes of *parasitic growths in the eye*.

The forms observed by Förster and Gräfe do not belong to leptothrix. In the cornea of an eye which had perished from panophthalmitis, he observed long, thin, opaque filaments; they are thicker than those of leptothrix-buccalis, show a tendency to twist themselves lengthwise around each other, or to assume a curved form. Attempts at cultivation failed, excepting in human blood; here the filaments lengthened, gathered themselves together in a curved form, showed transverse marks of segmentation, and divided into two to five pieces of different length; the process lasted from twenty-five minutes to one hour. The new pieces congregated, and thus formed additional bundles. This is a new form, leptothrix oculorum Sorokini. In an eye effected with panophthalmitis after iridectomy, and also in an existing catarrh of the lachrymal passages, he found filaments dividing dichotomically, having a thickness of two or three division-marks of the micrometer; they also exhibited transverse division, and thus formed widened rings. The twigs branch off only where there are transverse divisions. Besides these, there were folds of cells of various size and shape. All attempts at cultivation failed.

Leydig, of Bonn, speaks of *The Eye-like Organs of Fishes*.

Certain spots upon the ventral surface of some sea-fishes, which by Leuckart had been explained as secondary eyes, are not taken as organs of special sense by Leydig, who supposes that they are allied to the spendo-electrical or electrical organs of other fishes.

Wetschamton reports *An Anomalous Structure of the Human Eye*.

Absence of both irides. Both eyes turned in and up.

Wiethe. A case of *Congenital Deformity of the Pupilla*.

The papilla showed two dark elliptical depressions, likely colobomata.

Lagethschnikoff reports a rare case of *Elephantiasis Palpebrarum*.

Both lids are very much enlarged; the upper hangs down to the nasal angle. The disease began in early childhood. *Filaria sanguinis immitans*.

Gouvêa Hilario (de Rio Janeiro) reports a case of *Aniridia Congenita of Both Eyes, with Deficiency of Ciliary Bodies and Anterior Part of the Choroid*.

Man, 23 years old; complete absence of iris in both eyes; lenses dislocated upward, so that there was an aphakic space at the lower corneal margin. There was no sign of the presence of ciliary processes, nor of the anterior part of the choroid, while the posterior part was more or less normal, as were also the blood-vessels of the retina.

A knotty and most weighty question which is of the greatest interest to all medical men and parents is answered, and in our opinion well sustained by experience, in the conclusions of Berlin and Rembold, of Stuttgart, who say: "The present slanting system of penmanship should be retained, and the school-boards and teachers should understand the necessity and importance of these directions, so as to enforce them with the proper intelligence and energy." The best means to accomplish this seems to be the embodiment of a short abstract of B. and R.'s report.

1. The inclination of the letters. *i. e.*, the angle which the downward stroke makes with a line perpendicular to the ruling of the paper, should be 35° to 40°.

2. The book should not be placed to the right, but as nearly as possible before the median line of the body, and so inclined that the direction of the writing rises from the left and below to the right and upward at an angle of 30° to 40°.

3. The position of the body as follows: (a) The upper part of the body remains upright as far as

possible, so that it is supported by the spinal column, which is prevented from becoming tired by resting its lower portion against a support. (b) The transverse axis of the body, the connecting line between the shoulders, is parallel to the longer edge of the table. (c) The body must not be pressed against the edges of the table, but kept at a distance of about 3 cm. from it. (d) The head, whose transverse axis is also parallel to the longer edge of the table, is lowered but slightly toward the latter. (e) The elbows must be kept a little lower than the edge of the table, and at an equal distance from the body. (f) The forearms, not the elbows, are laid upon the table in an almost symmetrical position, the book being placed in the median line of the body.

4. This position of the body is to be maintained during the whole act of writing, the upper part of the body and the upper arms to the point of support of the forearms upon the table's edge remaining quiet, and the hand and forearm alone performing the act of writing. (a) The movements necessary to produce the letters and single words must be performed by the joints of the fingers and the wrist. (b) The right forearm must not move its point of support upon the table's edge outward, as the writing advances along the line, but must revolve about it as a centre, thus describing an arc upon the table. In order to facilitate adherence to the particular directions (only given here in brief), it is advisable, especially in smaller children, to shorten the lines. (c) When a new line is begun, the forearm must describe the same arc backward with greater rapidity. As more lines are written, the wrist and finger-joints must be more and more bent.

5. The head also must not change its position; the slight rotation from left to right in writing is not injurious.

*In view of the deleterious consequences of a too close approach of the eyes in writing, and the fact that in the youngest children this is the case to a very high degree, producing most unfortunate results, which for anatomical reasons cannot be obviated by changing the regulations, the following suggestions are made:**

1. Reading and writing, playing with small objects, in general work requiring close vision, should be forbidden in the schools for younger children, the kindergartens, etc., whence the children frequently enter school with eyes already myopic.

2. Instruction in writing should be limited as much as possible the first year; reading of distant objects (blackboards) should be first taught, then the books, and finally writing, the time not ex-

tending beyond half an hour the first years, and limited to five to ten minutes, followed by a pause of a few minutes.

3. The letters should be large, symmetry and beauty being of less importance.

4. The slanting lines of the blackboards and books should be omitted.

5. Writing, especially at home, should be limited as much as possible, and permitted only when the child's home is sufficiently light and airy.

6. The teachers should impress the children with the importance of assuming the correct attitude when writing at home. Instructions to parents would also be desirable.

According to Karwat Würzburg, the nutrition of the crystalline lens is impaired in atheroma of the carotid, a circumstance which materially favors the development of cataract. Embolism of the central retinal artery may also result.

Holstein, of Berlin, criticises the various reports on antiseptics in ophthalmology, and comes to the following conclusions:

1. The great danger of septicæmia, which threatens the body after severe surgical operations, need not be feared in ophthalmology, as the intra-ocular pressure and firm fibrous envelopes of the globe make septicæmic infection of the body very difficult. Therefore, antiseptic treatment is unnecessary.

2. The serpent ulcer, dacryo-cysto-blennorrhœa, and the specifically infectious conjunctival blennorrhœas, should be treated with antiseptics on account of their septic nature.

3. The strict antiseptic bandage, according to Lister, cannot be applied to the eye as it is not practical, as it irritates.

Boracic acid has thus far proven the best antiseptic. It does not irritate, but will disinfect.

Chisholm, of Baltimore, and L. Turnbull, of Philadelphia, recommend bromide of ethyl as the most perfect anæsthetic for short, painful surgical operations. Narcosis can be produced in a minute, and lasts two or three.

According to Mauthner, the electric light increases vision and color-perception. The arc-light is not steady, and therefore injurious; the incandescent is steady, and theoretically no objection can be made to it, but experience alone can decide as to its value.

Sakewitsch found a few cases of extraordinary acuteness of vision among the soldiers of the 14th regiment of Russian dragoons, two cases with $V = \frac{8}{20}$, three with $V = \frac{7}{20}$, and seventeen with $V = \frac{6}{20}$.

*Italics our own.—C. S. T.

According to Mari, *forty centigrammes of santolin are sufficient to produce an effect lasting twelve hours*. Bright surfaces appear a greenish yellow; dark ones, especially shadows, violet; red assumes a purple tinge; yellow seems pale; blue has a greenish tinge; violet and purple become darker; orange seems pink; greenish-yellow is changed to grey. The spectrum is shortened, especially at the violet end. In a violet-blind person the whole spectrum was displaced.

Dobrowolsky calls attention to the fact that most of the scholars of the Ural high school are children of *inhabitants of the prairies*, to which must be ascribed their *acuteness of vision* and the *rarity of myopia*, and not to the favorable hygienic condition of the schools.

Königshöfer says the *direction of the writing is entirely immaterial*, as far as the laws governing the movements of the eye are concerned. The sole cause of the various bad attitudes of the body is the attempt to find the most comfortable position of the wrist and fingers.

Makrocki saw several little *nodules in the upper lid* of both eyes of a lady. After incising the skin over them, several well formed lashes were extracted.

Berger describes two (extremely interesting and instructive) cases of *paralysis of the acoustic and fifth nerves, with paralysis of the facial nerve, due to the caries of the petrous portions of the temporal bone*. In one of the patients the cornea of the affected side had remained intact, though without sensibility; in the other, there was neuro-paralytic keratitis.

Hasner observed a *paralysis of the left oculo-motor nerve* in a girl seventeen years of age, which always occurred, for the four last years, *as soon as menstruation begun*, and lasted for three days. Hyperemia, due to menstruation, at the origin of the left oculo-motor nerve, was probably the cause, producing transient paralysis by pressure.

Thompson observed *painful blepharospasm*, and spasm of the ciliary muscle, *after exposure to the electric arc-light*.

De le Peña found an *echinococcus behind a highly diseased and blind eye*, which he had enucleated. Once before he had noticed a similar case. According to him, echinococcus passes through three stages of development, presenting the following symptoms:

1. Slight exophthalmus, with V. normal and tension normal, slight and transient pains.
2. Increased exophthalmus and decrease of vision and high tension.
3. Marked exophthalmus, dislocation of globe

outward—complete loss of vision, suppuration of the cornea.

P. Barabaschew reports another interesting case. Patient twenty-seven years of age, formerly a soldier. Marked *echinococcus exophthalmus* of right eye, chemosis painful, necrosis of cornea, V = 0, choked disc, the orbit filled with a smooth, tense tumor, distinctly fluctuating and dislocating the globe downward and outward. "In 1877, while he was a soldier, a shell exploded near him, and he became unconscious. After half an hour he recovered, when he noticed that vision in right eye was greatly impaired. Two months later the eye gradually began to swell. Diag. by exclusion; echinococcus of the orbit. When punctured f. 3 viiss. of colorless liquid was discharged (tracts of albumen, much Na. Cl.). After the puncture, severe reaction, oedema extending to the temple, lasting several days. Operated by making an incision at the upper inner edge of the orbit, preserving the globe. Fifteen larger and smaller echinococci were removed, varying in size to that of a pigeon's egg, and finally the original cyst. After the operation, severe reaction and slow recovery (as also in another case described some time ago by the same author).

Parigot, of Lyons, (Ferrier and others) recommends *inoculation against pannus*, and bases his claims on five cases which he cites. The pus should, however, be taken at the chronic stage of of blennorrhoea, as the affection produced is the less severe.

Wecker, of Paris, has made a series of experiments with the *infusion of jequirity* recommended by him for producing purulent ophthalmia to cure trachoma, and has arrived at the following results: Undoubtedly the infusion produces a purulent inflammation of a croupous character, the intensity of which can be regulated by the number of applications. The granulations rapidly disappear, and even if it should be necessary to produce this inflammation several times, the treatment is less disagreeable and dangerous than inoculation. The cornea is not endangered. W. says it is especially indicated in the torpid forms of granular conjunctivitis (trachoma). Wecker and Moura, of Brazil, claim priority in the use of jequirity.

Deuffe, Paris, reported at the Acad. of Med. de Belgique, March 31, 1883, on his *experiments on jequirity*, and to the conclusion, "the inflammation produced by it fails to accomplish any therapeutical results."

Gruening, New York, reports two cases in which he used *jequirity with excellent results*. One was a girl of 19, the other a man of 83.

Mazza applied *jequirity* in thirty cases of *trachoma*. Excellent results were obtained in five severe cases in which the disease had lasted four years, and there was extensive pannus; the cornea became perfectly clear. In five other cases improvement was not so marked, while in fifteen others no changes whatever took place; in the remaining five cases the result was absolutely negative. He never saw it make a case worse.

Paggi succeeded with *jequirity* in one case of *trachoma*, but failed in a second.

Ponti also applied *jequirity* in four severe cases of *trachoma* and *pannus*. Results were excellent, especially as to the clearing of the cornea. Besides the usual symptoms, he observed in two cases considerable *salivation*, and in one *profuse perspiration* and *nausea* at the height of the inflammation.

Simi obtained an excellent result with *jequirity* in a case of *mixed trachoma*. The disease had lasted two years, and had not yielded to various methods of treatment.

Tuberculosis of the conjunctiva has been seen in seventeen cases, so also *condylomata*.

CORRESPONDENCE.

A Reply to G. W. S., M. D.

EDS. MED. AND SURG. REPORTER:

Under the head of "Treatment Wanted" in May 31st No., page 701, by Dr. G. W. S., I have to say that I have found several cases very similar, occurring mostly in women, and have attributed them to irregular nerve or muscular action of the small intestine, the jejunum, from which a constipated condition of that portion prevents the passing downward of the bile, and after a time it is poured back into the stomach, where it is the source of great irritation. The remote neuralgic pains doubtless depend on the central irritation, while the pain at the pit of the stomach arises from muscular spasms of the stomach itself from the presence of the alkaline bile neutralizing the normally acid fluids of that organ. Of course the bile could never get back into the stomach except by being prevented from going downward, or by a reverse peristalsis of the jejunum or duodenum. When in the stomach it is a foreign body of opposite chemical action from the gastric fluid, and at once checks further transformation of food by the stomach. Not only so, but the nerves of the stomach are injured so that digestion is not soon started up again. Hence the importance of fasting after an attack of bilious vomiting, and the administration of an acid, particularly the muriatic, and pepsin, when food is given.

Thirty years ago I was in the way of giving such cases emetico-cathartics, so as not only to dislodge the bile, but to open the bowels and cause this downward action. This was a very effectual way to get rid of the trouble, but it was severe and

distressing, and required the detention of the physician till the first effects of the medicine at least were over. In recent years I quiet the pain at the pit of the stomach by hypodermic doses of morphia combined with atropia. The morphia so combined is much less sickening than when given alone. Having given the morphia, I give sulphuric acid to neutralize the alkaline bile and render the contents of the stomach acid again. The difficult part is now to be undertaken, that is to get the bowels open and acting downward once more. A large dose of calomel will do it after a time, but I do not like it. A saline, as the Rochelle salts, the citrate of magnesia, etc., will also do it. The best thing, however, is the sulphate of magnesia, with sulphuric acid enough to acidulate it, or the addition to the magnesia of the juice of a lemon. Plain water, or an acidulated water may be given, but no foods for some time, as they will irritate and delay recovery.

Having restored the gastric functions, the next thing is to keep the bowels henceforth free by the use of a mild aperient, as the cascara cordial in small quantities two or three times a day, or the infusion or extract of senna in combination with aromatics and calomel. Whatever laxative is used, it should be one which acts specially upon the upper part of the alimentary track, and not like thousand and one pills which glut the market, whose chief constituent is aloes. The treatment should be continued and supplemented with bitter infusions containing iron, through the intervention of sulphate of magnesia. To these nuxvomica or strychnine may be added. Rye pudding with cream for breakfast will save considerable other physic. Plain foods, with exclusion of pastries, sweetmeats, doughnuts, etc. All sorts of assasant fruits, particularly currants, with greens, vegetables, plain bread, etc., will do much towards a permanent cure of such cases.

For my theory of the torpidity of the small intestines, I have not the guidance of many authorities, yet the facts of such cases can more easily be accounted for on such a supposition than on any other. I have seen patients whose bowels in their lower part seemed to perform their functions fairly well, yet who were troubled with central torpidity. I think we have too often concluded that if the bowels acted fairly well in their lower part all was right above, and we have not taken into account that the liver and pancreas empty their contents into the canal some twenty feet from the outlet, and that therefore there may be chance for much functional disturbance of the upper part, with little show for it below, only a somewhat sluggish movement of the colon. Will not some others who have thought in this direction give their views of these cases of regurgitant bile? Truly, E. CHENERY, M. D.

Professor of Principles and Practice in the College of Physicians and Surgeons of Boston.

—M. Duprez, a veterinary meat-inspector, of Paris, fed some rats on trichinous meat for thirty-one days; they remained in perfect health. A piece of muscle was removed from the thigh of each animal, and was observed to be free from both young and encysted trichinae.

NEWS AND MISCELLANY.

The Kentucky State Medical Society.

HELD AT BOWLING GREEN, JUNE 3, 4 AND 5, 1884.

Reported by Alien Kelch, M. D.

The twenty-ninth annual meeting of the Kentucky State Medical Society was called to order at Bowling Green, by Dr. J. N. McCormack, president, at 2 o'clock, p. m., Tuesday, June 3.

After prayer by the Rev. J. L. Caldwell, Dr. T. J. Townsend, of Bowling Green, chairman of the Committee of Arrangements, was called upon, and spoke as follows:

"Mr. President, and gentlemen of the Kentucky State Medical Society: In behalf of the physicians of Warren county, it is my pleasant duty on this occasion to welcome you to Bowling Green. You could not have selected a place better suited for meeting than this beautiful little city. Adorned by every appliance that art with nature can contribute, it offers special inducements for business and social pleasure; and we would have you understand that our earnest desires are satisfied *only* when known that the object of your visit here is fully realized. You are with us at a time when your distinguished presence is most appreciated, and we know your coming is a happy day to the medical profession of Warren county. You are here to dispense harmony and affiliation, to encourage and perpetuate the fostered principles of progressive medicine, to read and discuss recorded observations that illumine and expand the great domain of medical science, and now we gladly welcome you to Bowling Green. To give expressions of welcome, this city will not be an exception to the time-honored customs of conviviality. Receptions and excursions have been arranged for your enjoyment, and in their order will appear in the printed programme. To-night, an address, "Cause of Consumption," Dr. J. W. Holland, Louisville, Ky. Wednesday evening, from 9 to 11 p. m., receptions by Mr. and Mrs. D. M. Lawson, Mr. and Mrs. P. J. Potter, Dr. and Mrs. J. N. McCormack, Residence street. Thursday at 1 p. m., car will leave depot for boat excursion through locks and dams on Barren river; will return at 9 p. m. Friday morning, excursion to Mammoth Cave."

Following this report of the Committee of Arrangements, the Hon. C. W. McElroy, in behalf of the physicians and residents of the city, delivered an eloquent and cordial address of welcome, which was responded to in behalf of the visiting delegates by Dr. Dudley S. Reynolds, of Louisville.

The regular proceedings of the convention were begun by the report of the Committee on Medical Ethics by Andrew Seargent, M. D.

Dr. J. P. Thomas, of Pembroke, to whom had been assigned the subject of *Materia Medica*, reported that he had given a fair test to the hypnotic paraldehyde, suggested as a substitute for chloral and opium, and his investigations had led him to regard it as a very mild hypnotic, adapted only for those cases of insomnia due to excitation of the nervous system. Kairine, as an antiperiodic and febrifuge, unless used in dangerous doses, he found not equal to salicylic acid nor quinine.

He remarked that he had unexpectedly produced almost fatal paralysis of the heart by its use in one case, with ten grains. Hyoscyamine in one case of insanity of the form of acute mania seemed rather to increase than allay the excitement.

DISCUSSION.

Dr. J. M. Matthews, of Louisville, said: "I take it the report of this committee is among the most important, and just one remark I was struck with and would like to have illustrated. He speaks of substitutes for chloral. I have used chloral for years, and from my own experience I must confess I am out with it. Its treacherous nature renders it a very uncertain and sometimes very dangerous drug."

Dr. J. W. Holland, of Louisville, said: "I had hoped to hear included the word opium in connection with chloral, in reference to their mutual action upon that form of insanity known as melancholia. Sydenham, however, called attention more than a century ago to the cordial qualities of opium. If there be already a melancholia, it proves more profound when chloral is employed than when opium is used, and the tendency to suicide is increased. I fear hyoscyamine is responsible for much the same effect."

Dr. Stone, of the Western Lunatic Asylum at Hopkinsville, said: "Hyoscyamine we have used not very extensively, but almost altogether hypodermically and in large doses, frequently attaining by this method as high as one-twelfth or one-tenth of a grain. In smaller doses we have kept it up for ten or twelve weeks, but we have found no material advantage from it over other drugs used to accomplish the same purpose. It will procure sleep, and that very promptly, in acute mania, and sometimes better than chloral. I agree with Dr. Holland as to the superiority of opium over chloral in melancholia. I have in mind one case, that of a lady who was kept on the chloral treatment for two years without improvement, and who, under a six-weeks' morphine treatment, recovered and was discharged. When chloral is used, we generally combine with it bromide of potash."

Dr. Pinckney Thompson, of Henderson, said: "I can not conceive that any man would expect chloral to cure anything other than that which it cures by the relief of a spasm of pain, such as a gastric neuralgia, where a full dose will often relieve at once, in this and such other affections as do not tend to recur immediately upon the cessation of the effect of the medicine. As to the danger from its use, the same may be said of all hypnotics when the dose is too large; they are all poison when used in poisonous doses."

Dr. W. M. Fuqua, of Hopkinsville, said: "I have used chloral from the very earliest introduction of it, but never to the extent I have for the last two or three years; as a remedy I think it has its place, and subserves a good purpose. It is for the discreet practitioner to find out that place, and govern his use of it by that dissemination. I think there can be no question that it produces, when long-continued, anemia of the brain; that it exercises a powerful effect on the cardiac centres, and that it is accumulative. The fact has not been referred to that it is anæsthetic as well as hypnotic."

Dr. R. M. Ferguson, of Louisville, read a paper on "Nature of Glaucoma." In substance he spoke as follows: "The special feature of glaucoma is the increased hardness of the eyeball. There are four ways of accounting for this, (a) hardening of the enveloping membrane from such change as calcification or ossification; (b) active contraction of the sclera; (c) increased secretion into the eye; (d) diminished secretion from the eye. He dismissed the first two methods of accounting for the hardness, because no facts support either of them in glaucoma. With reference to the third, but little is known, yet it is exceedingly probable that in many cases it is the initial step in the beginning of the disease. The continuance of the tension produces varied secondary changes. The constant teasing of the muscle in ciliary neuralgia might, it appears, bring about an over-abundant secretion of intra-ocular fluid. The fourth supposition offers more conclusive arguments to sustain it than either or all the others. In this direction recent investigations have yielded gratifying results."

Dr. Ferguson traced the natural direction of nutritive fluids from the ciliary processes to its escape from the eye, by means of the spaces known as "Fontana's spaces," about the canal of Sclemm, into which they open. Now, interference with this course results in non-elimination of intra-ocular fluid. It is certain that upon this hypothesis many cases of glaucoma can be explained, and that it offers the best explanation of that form of glaucoma least understood, viz., the simple variety. Many affections may cause a narrowing of the lymph-channels, each varying to a certain extent the picture of the disease, all however tending to the same result.

The speaker explained how enlargement of either ciliary body or crystalline lens approximates them, and thus narrows the circumlenticular space. Brailly's investigations having shown the lens to be contracted in the senile eye would not preclude the possibility of its having at a previous stage been enlarged.

Various congestions of the head would produce the same result by distension of the vessels. In irido-cyclitis, where the periphery of the iris is retracted, and in cases of iritis, where the pupillary margin is completely adherent to the lens capsule, and in other conditions arising from these, we have conditions favorable to the development of glaucoma.

This line of reasoning was continued until a very fine theory of the nature of glaucoma was evolved.

In the discussion of the paper which followed, Dr. A. W. Johnston, of Danville, inquired for a reason for the fact that seventy per cent. of cases of glaucoma occur among the Jewish.

Dr. Dudley S. Reynolds did not recognize such a statement to be a fact. He had observed the disease to be most frequent among those persons most liable to strain the power of accommodation, as among sewing-women, students, and watch-makers.

Dr. J. W. Holland, of Louisville, seeing the discussion about to drop, said that inasmuch as no one had been able to give an explanation of so singular a fact, he could only account for it on two grounds, and that was certain personal peculiar-

ities, and the fact that they did not eat pork. (Laughter.)

Dr. Wm. Bailey asked if it was not a fact that Jewish women sometimes had glaucoma. If they did, he would not accept the personal peculiarities of Dr. Holland's theory.

Dr. A. M. Vance, of Louisville, called the attention of the association to a new process for producing local anæsthesia for the minor operations in surgery. It consisted simply in the modified application of the spray of ether. Dr. Vance states that anæsthesia occurs long before the parts are frozen, and he begins his operations in a few seconds only after the spray begins upon the part, and has it played upon the parts just preceding the knife as the operation is continued. In this way an eye, he said, had been enucleated without general anæsthesia, a tracheotomy had likewise been successfully performed, and he had cut the whole plantar fascia in a child without a flinch beyond what was first made when the cold ether struck the part. He reported it to be his uniform custom to resort to it alone in all tenotomies.

Dr. Pinckney Thompson said: "I can conceive that if this could be done, it will remove one of the great dangers of tracheotomy. If it can be made to reach not only the skin but the deeper structures, it would add, in my judgment, many successes to that otherwise generally fruitless operation. As for myself, I have only practiced it in one instance of hæmorrhoids and in that it was certainly preferable to any general anæsthesia with which I have had experience."

Dr. J. M. Matthews said: "I have been exceedingly anxious to learn of some way in which to tie a man's piles without having to resort to general anæsthesia: I therefore tried this plan in several instances, but my experience with it has not been so glowing as Dr. Vance's has. In the limited number upon whom I have tried it, the pain following the operation has been excruciating."

Dr. Holland said: "We must not forget that he (Dr. Vance) proposes an entirely different process from that of freezing the tissues. Two reports, each very positive, and directly opposite in character, are here made to us, and I am therefore inclined to suppose that the results in the two cases depend upon the manner in which this anæsthesia is produced. In the meantime, I wish to impress upon the minds of the profession the necessity for care in the use of ether, on account of its inflammability. Tracheotomy is an emergency operation, generally performed at night and by artificial light, and it requires great care in handling this substance on account of its great danger."

Dr. T. H. Stucky, of Louisville, read a paper on "Catarrhal Headache."

WEDNESDAY FORENOON.

Dr. L. L. McMurtry, of Danville, read a paper on "Improvements in Surgery."

The first portion of the report was devoted to the consideration of the subject of anæsthetics. Recent investigations as to the comparative merits of sulphuric ethyl, ether, chloroform, bromide of ethyl, and anæsthetic mixtures of these agents, were reviewed in detail. The experimental inves-

tigations of Dr. B. A. Watson, of Jersey City, were carefully considered. His conclusions were, that sulphuric ether is decidedly the safest anæsthetic which has yet been employed in surgical practice, the mortality being relatively small when compared with that of chloroform, bromide of ethyl, and the mixtures employed. These results of experimental study are confirmed by clinical experience. Dr. McMurtry doubts if any agent will ever be found which can carry patients so near the border lines of life in safety. He doubts if anything is accomplished in avoiding danger, by the indiscriminate exhibition of alcohol before giving an anæsthetic. He then discussed the method introduced by Molliere, of administering the vapor of ether per rectum—the recent publications of Dr. William F. Bull, James B. Hunter, and Robert F. Weir, upon this mode of anæsthesia. The brief experience already recorded he claimed demonstrates the danger of the method, as exemplified by intestinal hemorrhage and diarrhœa; but the advantages of a method which suppresses the period of excitement, permits accurate regulation, avoids bronchial irritation, and aids materially in operations about the face, are apparent, and the method deserves to be tested thoroughly. In concluding this portion of the report, the speaker commended the ether inhaler of Dr. Allis, of Philadelphia.

The greater portion of Dr. McMurtry's paper was devoted to recent improvements in abdominal surgery. He discussed at length the treatment of wounds of the intestines, and declared the indications of treatment in contused, lacerated, punctured, and gunshot wounds of the intestines, preventive of fecal effusion and peritonitis. To secure the first, the wound of the tube must be securely sutured, however small it be. To do this, and cleanse thoroughly the peritoneum, the abdomen should be opened by abdominal section. The speaker in this connection called attention to the very confident views expressed by the late Dr. Marion Sims in 1882, which he thus quoted: "I have the deepest conviction that there is no more danger of a man's dying of a gunshot or other wound of the peritoneal cavity, properly treated, than there is of a woman's dying of ovariectomy properly performed," and remarked that in the able paper of Dr. Parks, recently given to the profession, on this subject, this statement of Dr. Sims was deemed prophetic.

Dealing with another branch of abdominal surgery, Dr. McMurtry alluded to the difficulties and uncertainties which surround the diagnosis of abdominal tumors. These difficulties were so great that in a large number of cases the diagnosis can only be positive when the abdomen is opened. He detailed illustrative cases from his own experience. In one case, that of a young lady with a fluid accumulation in the abdomen, the patient had been in the hands of several skillful surgeons, with a different diagnosis by each. After aspiration and the removal of two gallons of fluid, complete recovery ensued, thus showing the tumor to be a cyst of the parovarium.

After discussing at length the differential diagnosis of abdominal tumors, the speaker concluded with the statement that "while the results already achieved in the brilliant domain of abdominal surgery surpass the expectations of the most

speculative enthusiast of half a century ago, there remains a vast and rich outlying province as yet untrod by the restless foot of genius."

"There is one feature of the report," said Dr. A. W. Johnston, "to which I would call your attention, and that is the absence of any reference to the importance of drainage in the treatment of wounds of the abdominal cavity. It is one of the most important features of the after-treatment of these wounds. Lawson Tait speaks of drainage by the alimentary canal; he says he has made it a practice to purge these patients, and that he secures excellent results from the practice. We all know that when a purgative is given and succeeds in bringing an operation, water must come from somewhere, and this method I have found to act well in two cases recently under my charge. One of them exhibited marked improvement from the action of the purgative. His abdomen was distended, and he vomited frequently, but after the large dejections secured by calomel and podophyllin he recovered rapidly. After ovariectomy I think the large drainage-tubes now in use very much to be preferred over the small ones selected formerly. In one case upon which I operated, when the tumor was removed the attachments were found to extend all throughout the abdomen, and the large bleeding surface rendered the application of the persulphate of iron in some places a necessity. The large drainage-tube afterwards used permitted the clots formed by it to pass with ease."

Dr. D. W. Yandell, of Louisville, was understood to say: "With reference to the future of gunshot wounds of the peritoneum, as expressed by Dr. Marion Sims in the quotation read, the question was discussed a good deal between Dr. Sims and myself, and he took the extreme ground to which I objected then as now, as not expressing the real condition of our knowledge or resources. He says, 'I have the deepest conviction that there is no more danger of a man's dying of a gunshot or other wound of the peritoneal cavity, properly treated, than there is of a woman's dying of an ovariectomy properly performed.' That is to say that 97 per cent of wounds of the abdominal cavity ought to recover. There can be nothing certainly more misleading, both to the people who are, after all, our auditors, and to the profession, than that statement. What I wish to say is this: that you take the experience of the individual members of this society, and it will result that out of six cases of gunshot wounds of the abdomen, four will die—one of peritonitis, two of hemorrhage, and one of septicæmia. Two will die of hemorrhage, then, and two of something else. Now, in performing ovariectomy, you are prepared for hemorrhage, and you know when and where it will probably occur, and you are therefore prepared to meet it. Again, the shock is deeper from a shot-wound than from that made by the surgeon's knife, and the wounded person is seen for the first time in that condition. Further, no man has yet been so wise as to be able to say what course a ball has taken after it has once entered the body; and while I believe it is good surgery to open the cavity, as taught by the master of us all, yet there are many cases where it is not good surgery: that is to say, here is a man who has had a ball from a Derringer pistol pass

through him; you find him pulseless and cold—desperate. Under such circumstances I do not believe it is good practice to open the wound for anything. With cutting wounds it is quite otherwise; the shock is not so great. All about the wound the tissues are puffy, and it is evident hemorrhage is taking place. Under those circumstances the indication to open the wound and find the bleeding vessel is plain. All I wished to say was this—that the declaration of a great man, published in a moment of enthusiasm, is misleading; that the statement is not sustained by facts, nor likely to be sustained; and that shot-wounds are incalculably more dangerous than the knife of the surgeon in operations. I would therefore say, as a matter of consolation to gentlemen who meet with shot-wounds, that they need not recriminate themselves if the patient should happen to die, for they will sometimes, and that not infrequently, die from no want of proper attention.”

Dr. J. A. Larrabee said: “Of course I do not propose to discuss the surgical bearing of this paper. I noticed the remarks on anæsthetics, and it is of them I wish to speak. I object to the deductions on the use of chloroform. If a death occurs from its administration occasionally, it must not be forgotten that it is used in a very great number of cases. In the first place, this is, as I understand, intended to be pushed only to that extent sufficient to overcome the objections of the patient, after which profound anæsthesia is to be accomplished in the usual manner. That has been done in a limited number of cases, yet among that limited number one death occurred. It should not be overlooked that different means are to be employed for resuscitation according to the anæsthetic employed. When danger is threatened from ether, pulling out the tongue and stimulating the muscles of respiration are eminently proper; but with chloroform it is different, for the heart here fails first, and it is the organ to which attention must be directed.”

Dr. Stone, of the Western Lunatic Asylum, at Hopkinsville, spoke of the importance of resorting to every means at the command of the surgeon to avoid mistakes in diagnosis; and in connection with his remarks related the following: “Mrs. H—, æt. 35 years; German; very ignorant; was transferred to a metropolitan hospital from a county almshouse for treatment for abdominal dropsy. The history of the case, as given by the almshouse physician (the woman herself could give none), was that the woman was admitted five weeks before on account of abdominal dropsy, and five gallons of fluid withdrawn. She has three children, and has had two abortions. Abdominal trouble began six months ago. She was suddenly seized with pains in the back and side, which continued for a week, when enlargement of the abdomen became perceptible. Subsequently, vomiting continued for two months, enlargement still increasing. Ten days ago she was transferred to the hospital, her recovery from the tapping being sufficient to permit it. With history before him, an accomplished physician, after a cursory examination, pronounced it a case of simple ascites. Two experienced physicians were called in consultation, and discovered a tumor rising to an inch and a half from the umbilicus,

inclining to the left side. It was agreed to be a case of left ovarian dropsy. A week later, she was turned over to a distinguished surgeon for operation. He examined the case thoroughly and concurred in the diagnosis. The next day an eminent physician of large practice was called to see her. He made a thorough examination with the sound and otherwise, and concurred in the diagnosis and the advisability of early operation. Shortly after this examination, a slight bearing-down pain expelled a large clot of blood. A small opiate, however, soon removed all suspicious symptoms, and it was decided to operate on the fifth day succeeding this. The day following, the professor delivered a clinical lecture to a large class of medical students upon ovarian disease, its differential diagnosis, and the announcement was made of the operation upon the patient then before the class. An able obstetrician, a professor, and another of national reputation, finally called in late in the afternoon of the day immediately preceding that set for the operation. This careful specialist listened to the history of the case and all previous examinations, and proceeded to examine the tumor, first externally by palpation, percussion, etc., recognizing co-existing ascites. The sound passed $5\frac{1}{2}$ inches into the cavity of the uterus. I am credibly informed that this examiner diagnosed two tumors, one the enlarged and subinvolved uterus, the other of doubtful character. The sound when withdrawn, in this as in the other instances, was covered with blood, and pains came on soon afterwards. They now, however, assumed a more violent character, for which ten grains of Dover's powder was given. In fifteen minutes she passed from her vagina three pints of blood and water. The patient gave birth at 8 p. m. to a six and a half months' child, which lived until morning and died. The candid professor lectured that day upon ovarian tumors, and the various methods of discussing them, with the tumor before him. In this case there were several features to mislead even the most wary; but the recital of such things will, it is hoped, impress the importance of the very greatest care in such questions, where so much is involved.”

Dr. D. W. Yandell, of Louisville, was understood to say, “This is simply a report of one of our failures. If the faithful remained until all the faithful told their experiences, this society would last until Christmas. I know of two or three such cases as has been detailed. Professor Miller and Prof. Bayless diagnosed an abdominal tumor to be ovarian, and not until the woman gave birth to a child did they discover their mistake. Some years afterwards, a woman came from Mobile; she had a tumor; she was a widow: Parvin saw it; Miller saw it; Thomas saw it, and all declared it to be a fibroid. In the fall she gave birth to a child. There is a gentleman present through whose kindness I saw a woman four years ago. She had an enormous tumor, pronounced by myself, by Parvin, by Sam Gross, and *other eminent men*, to be an enormous fibroid. Time went on, she was given some muriate of ammonia and ergotine, and about a year ago she was seized one night with all the symptoms of peritonitis, collapse, and shock, and the gentleman called to her tapped her, and drew off a large quantity of fluid. I saw her, operated upon her, and while

the operation was all that could be desired, the woman died. That woman was seen by enough eminent men. These things show simply that the wisest and most experienced men make mistakes.

(To be Continued.)

Medical Society of New Jersey.

One hundred and eighteenth annual meeting, held in Cape May, Tuesday and Wednesday, January 10 and 11, 1884.

Tuesday.—The meeting was called to order in the Stockton House, at 4:30 o'clock p. m., by the President, Dr. S. Wickes, of Orange. Vice-Presidents Baker, Parrish, and Kipp were present. There was a large attendance of delegates and invited guests. After prayer by the Rev. G. F. Bishop, of Cape May, Dr. H. G. Taylor, Chairman of the Committee of Arrangements, made an address outlining the business and entertainments of the session.

Dr. Muray then delivered the

ADDRESS OF WELCOME.

"Mr. President, and Gentlemen of the Medical Society of New Jersey: It has fallen to my lot to extend to you a welcome, which I most heartily do, on this your second visit to our city. Since your last visit, in 1876, we have been visited by a destructive conflagration, sweeping out of existence all of our largest hotels, except this one in which you are now assembled. But Cape May, like the Phoenix, has risen from its ashes, and you now see in the place of the lost other structures equally imposing, two of which are brick, and all in architectural beauty and magnificence of appointments second to none in any watering-place in the world. We have here everything to please the eye, rest and refresh the body, restore health to the enfeebled, and give enjoyment and recreation to the seeker of pleasure. There are many things of which we feel justly proud: Our magnificent beach affording perfectly safe bathing by its very gradual descent, and regular, hard, smooth surface, with the fast land coming down to the very edge of the water. Our excellent, well-planned sewer system, laid down in almost every one of our streets, having sufficient fall to quickly carry off all effete matter far away from the town, giving such a sanitary condition that the mortality of both city and county is the lowest in the State. This is not a thing in prospect depending upon companies to complete, but *un fait accompli*, and that by our own efforts. Our State Board of Health, through its Secretary, has expressed unqualified approval and commendation of our system. Nor are our hotels or boarding-houses a whit behind in their internal sanitary arrangements. Not less than \$10,000 was expended in this hotel alone during last year in replacing and improving its drains and general sanitary arrangements. The same care has also been exercised in all our other hotels, both large and small. We believe we can safely assure our visitors against dangers from septic influences. Our water supply is in most excellent condition, furnishing about one million gallons daily, and distributed through all the most thickly-settled portions of the town, giving an abundant supply of excellent, pure,

fresh water, not from surface springs, but drawn from the very bowels of the earth, and stored in three large tanks, and from them distributed through mains to every part of the city, furnishing a freshly-drawn supply constantly, and not from stagnant ponds or reservoirs. Our fire department is worthy of mention, consisting of two steam fire engines of the best construction, with hose carts, hook and ladder truck, and a well organized and drilled fire department, a pair of well-trained, powerful horses, and kept by the city ready at the first tap of the bell to draw the engine to the place of danger. Our costly experience of '78 has led us to see well to it that every possible appliance is ready to meet such emergencies. Our beach-drive, extending from the western limits of the city to Cold Spring Inlet, on the very edge of the surf, a distance of four miles, needs no comment, as it is only necessary to see it to admire it. Then, too, with just pride, we can point to our noble iron pier, which you can now see nearing its completion—stretching out its long arms to the winged messengers of the deep, and inviting them to fold their wings and rest themselves by its strong sides. It is 1,000 feet in length, and 30 in width; at its terminal end a depth of 20 feet of water furnishes no less than six landing places for vessels, at which they may rest in security. It is built by the Phoenix Bridge Company, of Pennsylvania, whose very name gives a guarantee of its security and completeness. The immunity which the trend of the shore line, and a natural breakwater about two miles from the shore, gives us from the destructive force of the waves in heavy storms, will make our pier a resort for steam and sailing vessels during all the year. Then, too, not to be behind other places of resort, a noble elephant rears his huge head and body about one mile west of the town, and will undoubtedly be as great a source of wonder and amusement as the celebrated "Light of Asia" of Barnum, or at least of his compeers of other places. We would only mention our drives about the city, along the beach front, and throughout the country, as unsurpassed by any seaside resort. Our two railroads, the one $2\frac{1}{2}$ miles to Cape May Point and Steamboat Landing on the bay shore, the other to Sewell's Point, two miles to Cold Spring Inlet—both in a short ride carrying visitors to as good sailing and fishing grounds as can be found in the State. We will not consume your time by mentioning facts relative to our humidity, temperature, and prevailing winds, but would refer to a very able report of Prof. Smock, Assistant State Geologist, well worth perusal by all seeking healthful, pleasant resorts, either summer or winter. Some remarkable facts are brought to light in this report, giving us the advantage over all other seaside resorts in equableness of temperature in this country, with the single exception of Key West.

I fear, gentlemen, that I have already trespassed too long on your time and patience, and will therefore close by again bidding you welcome, hearty welcome to the hospitalities of our city, and trust that you will frequently in the future cheer us with your presence.

The minutes of the last annual meeting were read and approved.

On motion of Dr. Godfrey, a cordial invitation

was extended to all physicians of this and other states who were present to seats as corresponding members.

The following delegates from the Medical Society of Pennsylvania were present: M. O'Hara, J. Kean, H. F. Formad, W. Little, W. R. Crinnee, E. L. Evans, D. F. Willard, C. M. Seltzer, C. R. Pratt, W. P. Waugh, W. B. Ulrich, F. Woodbury, J. M. Backus, C. B. Nancrede, L. K. Baldwin, F. B. Hazel.

Dr. Ingersoll, delegate to American Medical Association, read his report.

Dr. D. C. English, delegate to the Medical Society of Connecticut, and Dr. Benjamin, delegate to the Medical Society of Pennsylvania, also read their reports. All were on motion referred to committee on publication.

Dr. E. M. Hunt stated that the Massachusetts Medical Society was in session at the present, and that our delegate, Dr. E. Worth, was in attendance at the meeting.

REPORT OF COMMITTEE ON MEDICAL ETHICS.

The standing committee acting as a committee on medical ethics would report in the case of appeal of Dr. Warman from the Mercer County Medical Society, that there is no ground for appeal.

Committee: T. J. Funk, E. J. Marsh, and S. C. Clark.

Dr. Wickes then read his address as President. The Doctor took for his subject "Living and Dying; its Physics and Psychics." He called attention to the mystery of life and its termination, and showed how at the beginning man, whose life was counted by centuries, and was terminated by the completion of time, was free from sickness and accidents, and vices due to heredity, and that these causes, active throughout the duration of man's existence on earth, have gradually reduced the individual's tenure of life to three-score and ten, with a limit of one hundred years. Buffon's researches in this connection were noted, and the ratio between the age of complete development and duration of life. He shows how this ratio is found throughout the animal kingdom, and deduces the law that governs the limit of man's life.

The importance of the physician properly understanding and appreciating the various phenomena indicating the approach of death and its presence was mentioned, and then the speaker described the way in which death makes its attack upon life. He described the symptoms present when death comes by the heart, the lungs, and the brain, and spoke of the importance of appreciating and understanding these phenomena in order to meet if possible the tendency to death. Graphically he pictured the oncoming of death, and the physiological course and results of the succeeding events in each case.

The evidences of impending dissolution were narrated: the restlessness, the decubitus, the catching at the bed-clothes, the automatic movements, the thirst, the changed countenance, the cessation of delirium, the gradual lowering of temperature, and the end.

The doctor further considered the signs of death—the cessation of function, the changes in the eyeball, the loss of heat, the settling of the blood

in the dependent parts of the body, the rigor mortis, and lastly, decomposition, first seen in the discoloration of the abdomen.

The act of dying was portrayed as one resembling sleep in every feature, except duration. Natural death is not painful; the old man, at the end of a long life of health, loses one by one his special forms of life, his senses, and at the end quietly, peacefully ceases to exist. But coming, as it usually does, to us through pain and sickness, death is feared as a painful event, but the actual cessation of life is not.

The "fear of death" was found present throughout antiquity, but only as a termination of worldly pleasures; even to the early Christian death was a joy, a pleasant exchange; it was the mediæval church that brought in the horrors of the charnel house into the daily thinking of mankind, and held up the fears of retribution to embitter the end of life.

The fear of death is mainly confined to the moment of death, and is found most active in those in the middle third of life. The very young can not understand it; the adolescent, in their strength, do not appreciate it. The old, by a curious mental process, become indifferent, and simply await the inevitable.

The conduct of the individual in the presence of death varies; many preserve consciousness to the last; many have illusions, and see visions; many seem to have deliriums; others, an exaltation of the spiritual sense.

These same hallucinations appear as dreams in sleep or as accompanying the phenomena of anaesthesia, and are not dependent, as often thought, on the development of the soul into a new life. "The mental experiences of the death-hour are quite uniform. Men usually die in the same moral and mental state in which they have lived. God does not in the final hour work a miracle to improve on the constitutional make which he gave at the creation."

The doctor closed by portraying the position of the physician toward his patient in the time of death, his grave responsibilities, and the necessity for having the honor and pride of his professional work take the place of greed for gain. The memory of a finished life he described as follows: "We have seen the fruitful overspreading tree against the cold auroral-tinted sky of a winter's sunset—its beauteous summer foliage withered and gone, its fruits all garnered—but its graceful and harmonious outlines tell of its spring bloom, its summer beauty, and its autumnal fruitage. It foretells as well its richer products in the future. So is a finished life: its fruitage is over, but its fragrant memories recall its outlines, full of grace and beauty, as they foretell the rewards in store for one who has served well his God and his fellow-man."

On motion of Dr. Garnett, the thanks of the society were voted to the president for his interesting and instructive address, and a copy requested for publication in the transactions.

REPORT OF THE STANDING COMMITTEE.

The report of the Standing Committee was then read by Dr. T. G. Smith, chairman:

This report is based on the reports of the reporters of the county societies. From these reports

it would appear, that during the last year there has been much less disease present than usual; the death-rate has been much lower. The direct dependence of this fact upon the meteorological conditions of the year is very evident; the cool summer, the prolonged autumn, with its bracing weather, the regular rainfall, the winter steadily cold without great changes in the temperature—all these conditions were favorable agencies in reducing the mortality from climatic causes.

Diarrhoeal diseases in the summer, and diseases of the respiratory organs were noticed of diminished severity, and much less prevalent. Epidemics have not prevailed to any great extent. Scarletina and diphtheria were much less prevalent than the year before. Measles was widely present, however, but mild in character and rarely fatal. Again, the common forms of fevers were less severe than usual.

The formation of the Cape May County Society is noted. This completes the roll of the county societies in the State.

The reports contain, also, individual reports of cases and the experiences in the treatment of disease.

Dr. Hulshizer advocates the use of larger doses of quinine than is common.

Dr. Way finds that salicylate of soda is the treatment for rheumatism. From various sources aconite in small and repeated doses is recommended in the same disease. The treatment of diphtheria is as varied as the reporters' names—steam, lime-water, tincture of iron, common salt, alcohol, bichloride of mercury, etc.

Dr. Morris reported a case of congestive chill relieved immediately by blood-letting. From Bergen is reported the value of aconite in pneumonia, this drug to be followed by phosphorus. In Monmouth county digitalis in large doses has been used in typhoid fever.

Dr. Downs reported a case of encephaloid disease of the omentum. A long illness preceded death, which was interpreted differently by various observers; an acute mania just previous to death drew attention to the brain, but an autopsy showed only the changes in the omentum, and which had not been recognized during life.

Dr. Miller reported a case of senile gangrene, with loss of nine toes by sloughing, with good recovery.

Dr. Phillips reports a case that he has twice treated for scarlatina.

Dr. Carell reported two cases of abscess between the folds of the colon, terminating by a discharge of pus from the rectum; also a case of kere-hepatic abscess evacuated through the lungs.

Dr. Lewis reported a case of hydrocele treated by injecting the sac with carbolic acid, with good result.

The following papers accompanied the report:

"A New Mode of Malarial Poisoning," by Dr. Stickler; "The Artificial Alimentation of Infants," by Dr. Turney; "An Epidemic of Scarlet Fever and Ulcerated Sore Throat at Bridgeport," by Dr. Oliphant; "Homœopathic Remedies," by Dr. Stephenson; "Venesection," by Dr. Morris; "Annular Disease of the Ear," by Dr. Chambers; "Chorea," by Dr. Clark; "Ovulation without Menstruation"—a case—Dr. Shannon; "Bright's Disease"—a case—Dr. Thomp-

son; "Histories of Several Interesting Cases," Dr. Welch; "Diaphragmatic Pleurisy," by Dr. Mebray; "An Extraordinary Case of Muscular Hypertrophy of the Stomach," by Dr. Marcy.

Among items of medical interest are noted the publication of the "Archives of Pediatrics," by Dr. Wm. P. Watson, of Jersey City; the establishment of a course of instruction in the diagnosis and treatment of diseases of the eye and ear, by Dr. C. J. Kipp, at the Newark Eye and Ear Infirmary; the successful progress of the "Society for the Relief of Widows and Orphans of Medical Men of New Jersey;" the "Progress of Burlington County Hospital;" the "Discontinuance of the Hospital for Women in connection with the Home of the Friendless in Newark;" the "Occurrence of Malarial Disease at the Newark City Home at Verona, its Relation to Polluted Drinking Water," and the "Establishment of a New Hospital," the "City Hospital," capacity about sixty beds.

The necrology of the year was as follows:

Dr. Rush Bateman, of Cedarville.

Dr. Paul S. Heritage, of Mantua.

Dr. J. C. Fitch, of Hope.

Dr. L. M. Osmun, of Phillipsburg.

Dr. J. A. Summerville, of Union Hill.

Dr. J. C. Weatherby, of Clarksboro.

Dr. J. W. Cuyler, of Morristown.

Adjourned for the day.

(To be continued.)

A British Tribute to the Late Professor S. D. Gross.

The *Brit. Med. Jour.*, May 10, 1884, concluded a very happily-worded obituary of Prof. Gross, as follows:

"His last appearance in England was on the occasion of the meeting of the British Medical Association at Cambridge, when he was one of the recipients of the degree of LL. D. conferred by the University in the Senate House. "To receive that honor," he wrote to the President, "I will come, old as I am, and liable to sea-sickness as I am." The venture was regarded with some anxiety by his family, and he was attended by one of his sons; but he came and returned in safety. He was warmly welcomed by his numerous old friends, and made many new ones, who will never forget him; and at his parting not a few tears were shed. Few who were present at the banquet in the Hall of Trinity College will have forgotten the most memorable incident of the feast, when the noble patriarchal form of Samuel Gross rose on the dais with folded arms, and addressing them as "men and brethren," in a speech of weighty words, well worthy of the man and of the occasion, bore testimony to the high merits of British surgery and the British nation, and expressed his strong conviction that two such peoples as the British and American must ever be united by the bonds of brotherhood and mutual admiration. He felt, and we must all feel, that this union, so important to the welfare of mankind, is not a little promoted by the fraternization of eminent men from the two sides of the Atlantic at the meetings of our great associations. The more our brethren from the far west come among us, the better shall we be pleased; and the more they resemble the noble man whose loss we deplore, the more sincerely shall we reverence and admire them."

Germanic Cremation in Russia.

The burning of dead bodies was an universal rite with the ancient Germans and the kindred Anglo-Saxons and Scandinavians. In *Fire Burial among our Germanic Forefathers*, by Karl Blind (Longmans & Co.), which gives a short "Record of the Poetry and History of Teutonic Cremation," the following occurs: "Among Northmen abroad fire-burial was continued down to the tenth century. In Orkney and Shetland the heathen Northmen practiced for at least a century and a half the fire-burial customs which they had brought with them from Norway. (See introduction by Mr. Joseph Anderson to the *Orkneyinga Saga*.) The same was done in the tenth century by the Warangian rulers of Russia, who had given the country a Norse dynasty and aristocracy, and probably even its name. A striking picture of those Germanic cremation rites in Russia has been handed down to us by Ahmed Ibn Fozlan, an Arab ambassador from the Khalife Al Moktador, who, in 921, wrote a report of his journey. His description is one of the most graphic, the minutest details being given. 'You Arabs,' said one of the Northmen in Russia to Ahmed Ibn Fozlan, 'are fools! You take the man whom you must have loved and honored, and put him down in the earth, where vermin and worms devour him. We, on the contrary, burn him up in a twinkling, and he goes straight to paradise.'"

The Sanitary Condition of To-day.

Dr. Wythe, in the *Pacific M. and S. Jour.*, for March, 1884, says:

"The sanitary condition of the great cities of the world to-day is vastly better than of those of the middle ages, although very far from what common prudence deems desirable. It is still true that people live longer in rural districts than in cities, yet ever since civilization began to inquire into and regulate public hygiene there has been steady improvement. Statistics may not yet be fully reliable, yet the best we have prove that life has been prolonged by civilization. According to Wagner, 'In the 20th year of life the probable survival was in the 16th century 22 years; in this century, 40 years.' Among children, the death-rate depends upon the social position or high civilization of the parents. In England, according to the tables of Mr. Ansell, of 100,000 children born alive, 74,000 will live at the end of their fifth year; but among the upper classes, who can afford the appliances of modern life, there will be 87,000, and among the peerage there will be 90,000."

Something of Interest about the Gorilla.

From a foreign exchange we learn Professor Alphonse Milne Edwards laid before the *Académie des Sciences*, at a recent meeting, a photograph of the young gorilla which has just died at the Jardin des Plantes. This little animal was the first representative of the genus gorilla that had ever been seen alive in Paris, this variety of anthropoid ape having been hitherto known only from descriptions of travelers and from the anatomical remains of individuals killed by the natives. Professor Milne Edwards gave an account of the

habits of the gorilla, and of its savage, untamable disposition, which, up to the present time, has rendered its education impossible. The intelligence of this ape, the largest and most formidable of all known species, is very far below that of other anthropoids, such as the chimpanzee or the gibbon.

Items.

—Bellevue Medical College has adopted a rule that its diploma shall hereafter be in English instead of Latin.

—Puscher, the Nuremberg chemist, says that paste made of starch, glycerin, and gypsum will maintain its plasticity and adhesiveness longer than any other cement.

—The palace of the ex-Empress Eugenie, at Marseilles, which she was obliged to give back to the city, has been turned into a medical school for the training of army medical officers and others.

—Drug clerk to diffident young lady—"Wish to get something?"

Young lady, muttering—"I really believe I've forgotten what I came for."

Clerk, who catches "onto" the last words—"Camphor; how much, please?"

—"Doctor," said the grateful patient, seizing the physician's hand, "I shall never forget that to you I owe my life."

"You exaggerate," said the doctor, "you only owe me for fifteen visits; that is the point which I hope you will not fail to remember."

—"Gimme foive eints worth o' medicin' in the bottle, wud yez?" said a wild-eyed boy of about fifteen, as he handed a pint bottle to the placid drug clerk.

"What kind of medicine?"

"Fwy medicin, av coorse, medicin; fwat d'yez suppose?"

"What are you going to use it for?"

"An' fwat's that to you? Gimme the medicin, an' be axin' no questions."

"Unless I know what you want, I cannot serve you."

"Ye can't! An' it's you a druggist an' not know fwat medicin is? Medicin! I tell yeez, med-i-SIN."

QUERIES AND REPLIES.

EDS. MED. AND SURG. REP.:—

Will you be kind enough to give in your journal soon some information in regard to the climatology of the western shore of Chesapeake Bay, the region about Fort Monroe and the sea coast of Virginia? Is it malarious along the salt-water shores at all seasons, or not so at any time, or only at certain times? Are malarial diseases prevalent at Annapolis, Patuxent river, Fort Monroe, Hampton and Newport News?

A CURIOUS CASE OF NERVOUS DISEASE.

BY THOS. D. WORDEN, M. D., PH. M.,
Of Saratoga, N. Y.

Medical men, having much to do with functional nervous disorders, speedily become familiar with their more constant yet multiform manifestations. Like the Old Man of the Sea, they metamorphose variously, and often curiously. Unaccustomed to the behavior peculiar to this class of cases, *i. e.*, neurasthenic in character, many a physician has been unable to find a satisfactory cause for phenomena to him so unusual and has accordingly suffered, perchance, no little *internal* bedside embarrassment at one time or another.

Having some personal knowledge of the truth whereof I speak, and desiring to contribute a stroke toward the filling-in and rounding-out of a picture by no means too finished, I am led to make a skeleton sketch of a case presenting incidentally some symptoms at once curious and unique.

Miss A—, æt. 25, has a long time suffered from an obstinate menorrhagia. Puberty was achieved with difficulty, and the menorrhagic condition, probably a result primarily of a faulty distribution of nerve-force, soon followed, and thus gradually aggravated the original nervous disturbance. On first examination, patient was found to be thin, anæmic, languid, and possessing little endurance. Spine was tender throughout, and constantly painful in lower half. Headaches (hemierania) frequent. Pain also in region of both ovaries. Uterus retroverted with endocervical inflammation. Palpitation occasional. Appetite capricious, and bowels inclined to constipation. Sleep very light and banished by trifles.

Nervous system greatly lowered in tone. Under treatment, all of these conditions by degrees improved, and at the end of four or five months quite a transformation had been wrought. At this time, a fall slightly concussed the spine, but the effects were soon removed, whereupon the previous general and special treatment was again resumed.

Two weeks ago I was hurriedly summoned at about 11 p. m., to see the young lady, and found her presenting the following curious and interesting symptoms: A tickling sensation in the throat had suddenly given rise to most violent, uncontrollable, and noisy paroxysms of coughing. Subjective sense of pharyngeal and laryngeal muscular spasms, but no dyspnœa. Intense burning and redness, with itching, then developed, extending over the chest, shoulders, neck, and chin. Lips swollen, dark, and painful. A lump, half the size of a hen's egg, rapidly appeared under the left ear, and there was a sensation of general swelling of the throat. Eyelids swollen. Head giddy. Pain so severe as to cause writhing and groaning was experienced just above the pubes and in the groins. Nausea ensued, culminating in free emesis—the pain, however, continuing without abatement.

These symptoms I have given sequentially as they occurred, and they were all compressed within the limits of forty-five minutes. Thinking that the violent coughing had driven the abdominal and pelvic organs down with such force upon the supporting pessary (Hodge's retroversion), as to possibly cause the intense supra-pubic pain, I promptly removed the instrument and then administered, *per orem*, morph. sulph. gr. $\frac{1}{4}$. Under this procedure all symptoms rapidly subsided, and beyond a little "uncomfortableness" the next morning, no disagreeable results remained. To me this was a very unusual manifestation. With no tendency to hysteria, and in the absence of any discoverable exciting cause, I can only look upon it as a rare and sudden disturbance of the equilibrium of nervous forces, resulting in the little tornado of symptoms which swept over the patient as above described. Has any one a better explanation to offer?

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - -	6.00
Physician's Daily Pocket Record, - -	1.50

PHILADELPHIA, PA.

THE IMPORTATION OF FOMITES.

At the time of the cholera scare last summer there was a vessel bound from Alexandria to Liverpool loaded with rags. The London newspapers became greatly excited at the prospect of having a pestilence thus brought to their shores. Their anxiety was promptly relieved by a statement of the owners that the infected cargo had been ordered to New York.

This is but one of many instances in which commercial interests have manifested a cynical indifference to the sanitary welfare of the public. In view of this, a very timely ruling of the Treasury Department has stringently forbidden the importation of rags from Egypt unless they have been thoroughly disinfected.

Directions for disinfection have been forwarded to our Consul-General at Cairo, and an inspector has been designated to supervise the process and furnish a proper certificate. It is recommended that one of the following methods should be adopted:

1. Boiling in water for two hours under a pressure of fifty pounds per square inch.

2. Boiling in water for four hours without pressure.

3. Subjection to the action of confined sulphurous-acid gas for six hours, burning one and a half to two pounds of roll brimstone in each 1,000 cubic feet of space, with the rags well scattered upon racks.

These precautions are very appropriate at this time; the more so, as rumors of the prevalence of cholera in the Red Sea ports of Egypt have already appeared in the European papers.

Although medical science has not discovered any remedy for this disease, it has made great and positive advances in checking its progress by hygienic precautions. It is the same with the bubonic plague, with malignant typhus, with contagious leprosy, and a large class of similar diseases. Our victory over them has been in keeping them at a distance. To aid in this, the resources of civilized governments are most essential.

NEWS AND MISCELLANY.

The Kentucky State Medical Society.

HELD AT BOWLING GREEN, JUNE 3, 4, AND 5, 1884.

Reported by Allen Kelch, M. D.

(Continued from page 785.)

WEDNESDAY AFTERNOON.

At the conclusion of the discussion of the report of the Committee on Improvements in Surgery, Dr. James S. Parrish, of Glasgow Junction, reported the following:

May 22, 1878, Mrs. R—, æt. 43, twenty years married, without children, was found to have an enlargement in the region of the right ovary, which had been perceptible for the past six months. To use the doctor's own words: "The uterine, or tumor, presented itself in the umbilical region, having a hard, movable surface, being a little to the right of the median line. Upon examination per vagina, the os uteri is found high up in the sacrum, and turned back towards the vaginal cul-de-sac very much shortened, and presenting a broad, indurated surface." At the end of the examination, says the doctor, the diagnosis not being made out (though I gave it as my opinion that it was an ovarian tumor) we all agreed to give the patient some general alternative treatment, and trust awhile to nature. The doctor says he "heard no more of the case until June 3, at which time he received a dispatch to meet the doctors at Smith's Grove for the purpose of aspirating the tumor. After another consultation, in which Dr. George Ewin was present, we agreed to aspirate the tumor with a view of its shedding more light upon the case."

This was done on the 4th of June, and a small quantity of straw-colored fluid drawn off, when, syncope supervening, the operation was curtailed and another consultation held. The following, and for several days subsequently, her pulse was 110 to 118, and temperature 100½ to 102, followed by diarrhœa.

To cut a long story short, she was removed to her home in the country, about fourteen miles, on the seventeenth day after the operation. About a week after, she was seized with severe pains, and her husband, a Rev. Mr. R., sent for the nearest physician, some two miles away, and in the meantime, while awaiting his arrival, his wife was up over the vessel, when she felt something give way, and commenced passing out at the bowel. The Rev. Mr. R. grew very much excited to see this, and on the arrival of Dr. H. he expressed it as his opinion that the sac of the tumor had passed. The doctor submitted the case with a hope that the society would express an opinion as to whether or not it is an ovarian tumor with sloughing and spontaneous cure, or what character of tumor it might be.

Dr. Pinckney Thompson, of Henderson, read a paper on Typhoid Fever. He said: "As I am on record in the last publications of the Kentucky State Board of Health as to the etiology of typhoid fever, it is not now necessary for me to repeat those views already expressed. In the limited time of a paper before the State Society, it is impossible to speak of its pathology, and I have

therefore to-day concluded to speak concerning its treatment.

"It is of the utmost importance that an early diagnosis should be made. When a doubt exists as to the character of the case, which is not infrequent, as sometimes continued malarial fever closely simulates it, my advice is to test it with such remedies as will remove the doubt as to its malarial character. This being done, and the typhoid nature of the disease established, the next important matter is to consider what are the dangers and what the remedies as the case progresses.

"Typhoid fever is a disease that has a distinct clinical history, runs a distinct course, and in my judgment is never aborted by remedies. The two first great important conditions to consider are the heat that necessarily develops—the consuming fire—which, in my judgment and experience, the majority of patients succumb to, and the involvement of the heart in the way of partial paralysis. In making the diagnosis of typhoid fever, it is not necessary to regard some disturbance of the alimentary canal as an essential factor to establish the existence of the disease. In some of the cases of the most inveterate type, I have found no such disturbance, but on the other hand a sluggishness amounting even to constipation. One case in particular impressed me. I saw a case in consultation some three years ago, a young lady 22 years of age. She had been sick twenty-two days. When I first saw the case, I pronounced it my opinion that the young woman had typhoid fever. Four days later she died, and twenty-four hours after death the autopsy revealed a perforation of the ileum.

"In controlling the heat that is usually developed in this disease, there is nothing so efficient in my experience as cold water. It need not be so cold as to produce the shock which is objectionable. I do not believe it necessary ever to have it below 75° or 76°, nor above 90°. It abstracts the heat, and should be repeated as often as necessity requires as guided by the thermometer. The manner of applying it is of the utmost importance. The immersion bath has been recommended. This not only involves considerable expense and inconvenience, but is oftentimes impossible to accomplish. I prefer the sponge bath, which is easily applied, not expensive, and in the hands of every one. It should be used as heat demands.

The next important thing is to sustain the heart's action, and the best agent to accomplish this and lower the temperature is, in my experience, alcohol. Another important remedy I have found satisfactory results from in the early stages, in reducing the temperature and controlling the circulation, is salicylic acid in ten, fifteen, or twenty-grain doses. It must be watched, however, on account of its depressing effect upon the head.

Digitalis, in connection with mineral acids, as recommended by Dr. Flint, especially in connection with phosphoric acid, has given in my hands excellent results. I have also given the acids with strychnia. In the latter stages of the disease, used in connection with belladonna, the heart's action is sustained, while at the same time the bowel troubles have been greatly mitigated. When, in spite of all, an excessive diarrhœa with a

tendency to fatal hemorrhage supervenes, I know of nothing better than opium and subnitrate of bismuth.

An important feature of typhoid is the frequency with which intolerance on the part of the stomach manifests itself. I have seen cases where ice and subnitrate of bismuth were equally promptly expelled, yield at once to iodine largely diluted in water, given every thirty to sixty minutes, or two hours, as the case may require.

It is not necessary here to speak of the necessity for cleanliness in all respects.

In conclusion, let me assure you, gentlemen, there is no disease the physician is called to treat that demands from first to last a more rigid adherence to the principle of symptomatic treatment than typhoid fever.

Dr. J. L. Taylor, of Greencastle, reported a case of typhoid fever which presented a typical history of the disease up to the eleventh day, at which time the temperature fell to 97°, and continued so through all the remainder of the case, which was characterized otherwise by the usual symptoms up until the twenty-second day, when it rose to 99°, and continued to vary for a few days, when convalescence was declared.

Dr. Wm. Bailey, of Louisiana, said: "I regret exceedingly that the first paper did not discuss the disease rather than the treatment, because the whole rational treatment of the disease depends upon the conception of it which is formed. I think it a specific infectious disease, due to a poison which produces it and no other malady. I believe it to be due to bacteria—that we have the passage of it through the system bringing about a group of symptoms separate and distinct, which we call typhoid fever. With this consideration then we would be prepared to discuss the paper by Dr. Thompson. This specific poison in the system brings about many important changes besides those it works in the alimentary canal. Not more than 10 per cent. of the fatal cases occur through any lesion of the intestinal tract, though diarrhœa and hemorrhage and perforation are features we must not neglect.

"The disease is fatal in exact proportion to the duration of an elevation of temperature. Undue elevation unduly prolonged lies at the root of most fatal cases.

"I am a confident believer in the benefit that comes from the reduction of temperature by antipyretics. Of them some have been commended, some have been rejected. I think no man, since the article on typhoid fever by Leibermeister, has a right to reject these remedies until they have been given an extensive and impartial trial. No man ought to speak against the antipyretic efficacy of quinine until he has given it in antipyretic doses. I know of no reason why quinine should be more objectionable to the stomach than salicylic acid.

"Alcohol, when we begin to near the natural termination of the disease, meets a good indication in supporting a weakened heart. To it alcohol acts in the nature of both the 'oats and the spur.' It feeds the heart by the stimulation and dilation of its own vessels; and as to quinine, I would advocate its employment in antipyretic doses whenever the thermometric record runs above 104°. This occurs about the third week of

the disease. Having given a decided dose, say twenty grains, I should expect to find no indication to repeat it short of forty-eight hours, because the temperature does not again readily rise."

Dr. J. A. Larrabee "desired to congratulate the doctor on the course advocated, as it augured a disposition in the management of typhoid-fever to return to first principles. It is beginning to be discernible in the discussions of societies, that symptoms which are valuable to the physician at the bedside exert a controlling influence upon the measures of treatment adopted. All rational physicians ordinarily at some time in the course of typhoid fever resort to the use of alcoholic stimulants. That alcohol reduces temperature can no longer be doubted; the manner in which it does so should occupy some attention. I can not agree with Dr. Bailey that it acts as the 'oats and the spur.' It decreases temperature by paralysis of the arteries, allowing the blood to flow more freely to the surface. If this be the case, it must lessen instead of increasing arterial tension. In regard to salicylic acid, I must add my testimony from my own experience to that which has gone before, that, while it is a very powerful agent to reduce temperature, it does it at the expense of the circulatory system. It produces exactly the same disturbance as quinine, only more intense. Digitalis, I recognize as a heart food, but even it must be used with caution, for it is not without danger. The heart belongs to the body and shares in the general debility, and under digitalis too great a muscular tension may destroy life by the spasmodic closure of the ventricle. With regard to the management of the intestinal trouble, turpentine has long enjoyed a deservedly high place in the professional estimation. When the dry tongue appears, when there are present evidences of inflammation of the mucous membrane, then the astringent, alterative effect of turpentine is desirable.

"The thermometer is undoubtedly a great benefit to the physician in these cases of typhoid fever: by watching its markings the danger is frequently pointed out before it is upon the patient. That high temperature is a factor in producing death cannot be doubted. That we can abort the disease is not held at the present time; we are therefore in for the management of it, and the word management is perhaps more expressive of our objects than the word treatment.

"With regard to the reduction of temperature by water, I think it a good plan, but I would not advocate the immersion of the body; especially are the movements necessary to accomplish this of great harm in the trembling stage of the disease.

"In malarial districts we often have a prodromal stage, resembling typhoid fever, and this is followed only by malarial fever; but by practice the early indications of typhoid fever become impressed upon the physician. There is a manner, an appearance, a language of the body, that stamps the man who is about to have developed this disease, which marks it above everything else."

Dr. D. W. Yandell, of Louisville, was understood to say: "I feel really there is no subject that possesses more interest than this, because this is a general interest. It is interesting to me

to note the treatment at the present as compared with the treatment 24 or 25 years ago, which I suppose was fairly represented in the treatment of my own case at that time. I thought it was malarial in the beginning, and I took forty grains of quinine, which served to increase my headache and general discomfort. Dr. Rogers came and prescribed sixty other grains in three separate doses. I was soon very deaf, and have not recovered to this day; not because of the quinine, but because of other troubles. Rogers thought I stood a good chance of dying in the first week, of nausea, but I finally passed over that period, and then during eight other weeks I was delicious. Throughout the whole of that time I was required to take food every three hours, and then every two hours, and then finally every hour. I was constipated for a week at a time; at the end of a week I would have an injection, and finally, three weeks after the delirium had passed, I was able to stand up. I am satisfied that in this case food was sometimes given at the expense of my convenience, therefore in my own person I have been trying Tanner's method somewhat. In an attack of rheumatism two years ago, thinking it might possibly help me, I made a fast of eleven days, but it did no good. I commenced taking food again, and in due time it passed off. In the winter just passed, I fasted twenty-one days, literally without food. At the end of that time I did not feel any particular inconvenience nor loss of strength. In the last two years I have treated five cases of typhoid fever in this way; that is, I have been governed entirely by the desires of the patient. Food was forced upon me for nine weeks; I took it, never without remonstrance, and always with disgust. Last July I treated a case in the person of a young man from Lexington. He went seventeen days with about two or three glasses of water. During that time he had one or two actions from his bowels; on the twelfth day a little diarrhoea, for which he took some chalk mixture. He made a good recovery; got well somewhat more rapidly I think than ordinary cases.

"Touching the use of quinia. In 1865, Dr Rogers and myself were thrown much together. The result of his experiments and my own carried out through '65 and '66, was to this effect, that at no time in the history of typhoid fever or typho-malarial did quinine produce any perceptible good, but that after the fever began to subside, to show some disposition to take a periodical form, at that time it was beneficial. I was quite surprised to hear a gentleman say he had encountered no inconvenience from these large doses of quinia. My observation has been just the reverse. The sixty grains made me just that much more wretched, irritable, and excited. I remember to have seen a case in consultation with Dr. Foree (and I think he was one of the most sagacious practitioners I have ever known), in which the disease in the person of a doctor lasted twenty weeks. Time and time again the question was discussed between us when his temperature ran high; still we withheld it till the fever showed a disposition to abate or assume a periodical type. At the end of that time it fell to 100°, then rose to 102°. Foree said, now is the time for quinine. I gave him ten-grain doses every two hours until he had taken forty grains. It reduced his tempera-

ture, and it remained down from twelve to eighteen hours, then it went to 104° again.

"These are the experiences of Rogers and Foree; my own is to the effect in typhoid fever precisely as in surgery. You can reduce the temperature with quinine or salicylic acid as low as you choose, and keep it there under the continued administration of the drug, but the moment you withhold it, the temperature goes back to where it was, and sometimes beyond. I have yet to see that quinine possesses any real power over the course and progress of that malady.

"Now, with reference to the use of water. The application of the wet sheet, as practiced with my father, won the prize for the best essay on this fever in 1840. I was glad to hear the gentleman say he used hot water. It reduces the temperature in the course of an hour, and I think it a good plan to sprinkle the blanket with water at such temperature as proves grateful to the patient.

"So, then, the three points I make are, first, as to food; next, that quinine possesses no curative powers whatever in this disease, and whatever good it does is purchased at the expense of the comfort and convenience of the patient; and next, that water is the best antipyretic, when properly used, that we possess for this disease."

Dr. Holland agreed with Dr. Bailey as to the efficacy of large doses of quinine at long intervals, and had seen excellent results from the practice. Given fifteen grains in the early morning, patients will rest comfortably throughout the day frequently, and pass a better night, feeling refreshed from its effects.

At the conclusion of this discussion, Dr. D. W. Yandell presented to the individual members of the Society the following memorial, neatly printed on handsome sheets for framing:

In Memoriam.

WITHIN THIS URN LIE THE ASHES OF

SAMUEL DAVID GROSS,

A MASTER IN SURGERY.

His life, which reached the extreme Limits of the Psalmist, was one unbroken process of Laborious Years.

He filled Chairs in Four Medical Colleges in as many States of the Union, and added Lustre to them all.

He recast Surgical Science as taught in North America,
Formulated anew its Principles,
Enlarged its Domain,

Added to its Art, and imparted fresh Impetus to its Study.
He Composed many Books, and among them,

A SYSTEM OF SURGERY,

Which is read in different tongues, wherever the
Healing Art is Practiced.

With a Great Intellect, carefully trained and balanced,

He aimed with undivided Zeal

At the Noble End of Lessening Human Suffering

And Lengthening Human Life,

And so rose to the Highest Position yet attained in Science

By any of His Countrymen.

Resolute in Truth, he had no Fear, yet he was

Both Tolerant and Charitable.

Living in Enlightened Fellowship with all Laborers in the

World of Science,

He was greatly Honored by the Learned in Foreign Lands
And deeply Loved at Home.

BEHIND THE VEIL OF THIS LIFE THERE IS A
MYSTERY WHICH HE PENETRATED ON THE

SIXTH DAY OF MAY, 1884.

HIIS MEMORY

Shall Exhort and his Example shall Encourage and
Persuade those who come after him to Emulate
Deeds which, Great in themselves,
Were all Crowned by the Milk-white Flower of a
STAINLESS LIFE.

Dr. A. W. Johnston, of Danville, read a paper on "Bigelow's Litholopaxy." Briefly he began by urging upon the profession a more careful investigation of their urethro-vesical cases: stating that as they are now managed, many stones are found for the first time on the autopsy table. Before we had so many instruments of precision, this might be pardonable; but now a practitioner is as often to blame for letting a man die with a stone in his bladder as he was in old times for cutting him when none existed. Stone is never the disease itself, but only a symptom or complication of some other trouble, and therefore it should be carefully and repeatedly sought for in all persistent cases. By personal experience he recommended the use of Bowman's stethoscope in auscultating the vesical region while the sound was moved about the bladder, as it magnifies the sound of small and soft phosphatic stones, as well as giving an intelligent idea of the condition of the vesical wall. The statistics which he gave on the various methods of removal were for lithotomy one death in eight between 17 and 40, and one in four above that age, while nearly all recover below 17. The best that ordinary lithotripsy had ever done, in spite of the most careful selection of cases, was one in seventeen, whereas litholopaxy, taking nearly all stones and constitutions to adult life, loses only one in 334.

Formerly every small soft stone in otherwise healthy patients was crushed. Now, however hard uric, weighing as much as 1,000 grains, and good-sized oxalates, are successfully removed from patients with almost all sorts of known complications, the organic obstructions only serving to make us more careful in the operation. F. N. Otis made this operation possible by demonstrating the real calibre of the urethra, but to Bigelow belongs the credit of connecting the tolerance of the bladder that had already been seen by several, with Otis' ideas—and then litholopaxy was born. The operation is being done on a large scale all over the known world, except in the Western, Middle, and Southern States; and the only reason that he could give for its backwardness there, was their proverbial dislike of details—for as in ovariectomy and extraction of cataract, it is now proved that it is gentleness and not dazzle that the bladder most approves.

He then gave a case in detail from which two months before he had removed 300 grains of phosphates through the narrow urethra of an enlarged prostate, the patient receiving great relief. As he did not bear the anæsthetic well, the operation had to be stopped before all the fragments could be removed, about forty grains being passed since. From the paresis caused by the hyperdistention of the bladder from the amount of water used, the organ cannot wound itself on small particles left behind, and we do not fear the reactions where only the amount that the viscus is accus-

tomed to is used. However, we should not trust to this, except where we are forced to, but should remove every particle that can be found. As the prostatic bar could not be safely removed, he expected to have to watch his patient carefully for some time to come, as it might again start the same chain of sequences, and like Thompson, he might repeatedly have to remove small concretions; but as he was 60 years of age he did not fear much reaction, for, like Freyer, of Calcutta, he thought the young and strong were more liable to urethral fever.

In speaking of the complications of stone, he said he wanted to enter a protest to what he had once heard a leading surgeon on the New York Hospital staff say, and that was, that by no known method of examination of the urine could we get a satisfactory idea of the mischief that has been done to the kidney by this sort of irritation. Time would not permit him to speak in detail, but he was sure the close study of the renal detritus would reveal its true condition. Large oxalates must still be cut. The dangers of the operation are of the operators' own making, and begin with the selection of instruments and last all the way through. No step is free from danger to the patient and disaster to the operator, if he does not know what to do and how to do it gently. After going over the various accidents that are most liable to happen to an operator, and giving the way to prevent each, he concluded with the statement that "the greatest dangers are of the surgeon's own making, and that it behooves him not only to be careful in the selection of his instruments, but in every movement he makes with them. No one should undertake this who is not personally familiar with all the urethro-vesical disorders and who is not already a tried surgeon, for in no position could an excited operator do more harm. To those stone operators who have not yet learned this method, I would say, learn it as quickly as possible, for the time is not far off when you must use it or give up your practice. The professional eye is rapidly learning to read the handwriting on the wall, and be assured that it will be but a short time before the uninitiated will with them exclaim: 'Mene, mene, tekel, upharsin!'"

Dr. D. W. Yandell, of Louisville, was understood to say: "I may state what will probably interest the Society, that the two men at the International Congress, two years ago, who attracted most attention after Pasteur, were Bigelow and Billings. Bigelow handles his instruments like a magician. My own experience with instruments is that after they are tested they are more liable to break than before. I had one of Bigelow's instruments sent to me by his own maker, and the first attempt I made to use it, it broke, and I had afterwards a very difficult cutting operation to do to get out the fragment as well as the stone. Fortunately, the case recovered."

Dr. Dudley S. Reynolds, speaking on the subject of "Inflammations of the Iris," said in brief: "In order to properly discriminate between various forms of inflammation of the iris and to distinguish these from malarial and tubercular, and certain tumors which are liable to develop in this structure, a little attention ought to be given to the anatomical peculiarities of the iris. It is a network of yellow elastic fibre with fine connec-

tive tissue fibre holding the pigment in place. The pectinate ligament of the iris, which is formed by deflection of the posterior elastic layer of the cornea, serves not only to bind the iris securely to the cornea, but the slips of this ligament are divided continuously to their point of attachment by fusion with the sheath of the constrictor pupillæ muscle. The sphincter muscle of the pupil is the only muscular structure in the iris. It has no radiary muscular fibres, as some seem to think, and as has been long taught by book-makers; it has no arteries nor veins. Its blood-supply comes from a large number of minute arterioles belonging to the long ciliary arteries. These arterioles belong in the network of capillary vessels which ramify the interstices of the iris, and return by venules which begin at the periphery of the iris and lead into the sinus, called the canal of Schlemm. This canal contains a plexus of veins and a large number of lymphatic vessels. When the pupil of the eye is contracted, the iris is brought more firmly into contact with the capsule of the crystalline lens. Any irritation in the nature of congestion contracts the pupil, and even the mildest form of inflammation of the iris will in a short time develop adhesions at the point of contact between the iris and the capsule of the lens. This is the great danger in all inflammations of the iris, whether traumatic, syphilitic, miasmatic, or tuberculous. The chief point to be considered by the practitioner is that all forms of iritis require precisely the same local treatment, that this treatment is demanded from the very beginning of the first stage of the inflammatory process until the last vestige of it has disappeared. It is customary to commend the sulphate of atropia for this purpose; and whilst it is in most cases promptly efficient, there are certain objections to it. The only object to be secured by any local treatment in any form of iritis is to dilate the pupil and relieve pain. It unfortunately happens that the sulphate of atropia, whilst it uniformly dilates the pupil, does not always relieve the pain; per contra it sometimes greatly intensifies it by increasing the tension of the eye, and in this often endangering the safety of the organ. The hydrobromate of homatropia, in my own experience, which extends over a period of more than two years of active practice, both private and at the hospital college clinic, covering hundreds of cases, induces me to rely implicitly upon it for a prompt dilatation of the pupil and a prompt diminution of the pain. In all forms of iritis I use a solution of homatropia in the proportion of one grain to the drachm of distilled water, and this instil into the eyes, one drop every five minutes, until the pupil is dilated and the pain abated. I prescribe an interval of not more than three hours for the repetition of the local application. I have never witnessed any constitutional disturbance from the use of this solution, even in children as young as seven years of age.

"All forms of iritis, except the traumatic, require constitutional treatment based upon a consideration of the case, and nature of the constitutional disease which has its local manifestation in the iris. I have seen violently acute forms of iritis arrested in forty-eight hours by the administration of an aperient, followed by one decided dose of quinine, say fifteen or twenty grains of

the sulphate, the local treatment being promptly and persistently carried out. Cases of syphilitic inflammation of the iris require, of course, to be discriminated, if it is possible to do so; if the inflammation has its seat in the iris, gummata will appear in the substance of the iris upon its surface, and upon the margin of the pupil. These will be recognized by a nodular elevation, by interstitial circumscribed swelling, or by tubercular projections from the margin of the pupil; but in some cases the syphilitic manifestation is not present in the iris—it may occur in the ciliary body, in the ciliary muscle, or in the canal of Schlemm, producing an iritis often more difficult to control than that which has its origin in the iris proper. The iodide of potassium in progressively increasing doses, taken always in a glassful of cold water and at intervals of four to six hours, with the local use of hydrobromate of homatropia, and smoked glasses to protect the eyes from light, constitute as nearly a specific line of treatment for syphilitic iritis as one may desire.

"To recapitulate now: all forms of iritis should be treated by the local application of some non-irritating mydriatic, the best of which is hydrobromate of homatropia; next to this, daturia stramonium, or its alkaloid, the sulphate of daturina; next to this, the sulphate of atropia or duboisia. The constitutional treatment shall be of the nature suggested by the character of the constitutional disease which has caused the iritis."

THURSDAY'S SESSION.

Dr. T. D. Finck, of Louisville, read a paper on "Phlyctenular Conjunctivitis." As illustrative of a want of thorough investigation of the pathology and etiology of very common diseases, he cited two cases occurring in children subsequent to an attack of measles, and which by many practitioners would be said therefore to be due to that as a cause.

"These cases," said he, "are interesting, inasmuch as this disease counts amongst its sequelæ catarrhal conjunctivitis. But the pathology of phlyctenular conjunctivitis consists in a rupture of a lymphatic in consequence of an engorgement. Lymphatic inflammation is attended by increase of the lymph-cells both in number and size; the vessels are burdened, and as a consequence rupture occurs.

"That the herpes spring up at the corneo-conjunctival junction is due to the fact that the conjunctiva, loosely attached to the globe until reaching the cornea, becomes here firmly adherent to it—then the net-work of lymphatics, having its zone-like origin around the cornea and having its periphery encircled by a large lymphatic, which anastomosing with the net-work around the cornea and at the same time throws down branches to open into the axial lymphatics, which are subsequently united to the submaxillary glands.

"When it is remembered that enlargement of the glands of the neck invariably co-exists with conjunctival herpes, these facts not only explain the reason for the location of the herpes, but go far to prove that phlyctenular conjunctivitis is due to a glandular engorgement, and that measles could only then be considered a factor in its production when regarded as a debilitating cause."

Dr. W. M. Fuqua, of Hopkinsville, read an ex-

haustive paper on "Civilization and Sanitation." In brief Dr. Fuqua took the grounds that disease is very much more frequently of centric than excentric origin, and that therefore much of the present sanitary doctrine is unsound. "Sanitary science, says a recent writer, begins and ends with man; its aim is the growth of an improved race; a healthy, useful, and long life. Public health ever goes hand in hand with true liberty, and is the companion of orderly habits and pure morals. Does civilization essay to do more than this? Are they not mutually interwoven, one the handmaid of the other?"

"Man's duty to himself in the present age is measureless; its path is as broad as the ship's road upon the wide ocean plain. What the present asks is the deepest solicitude of each individual over itself, because a high state of society or civilization, or sanitation, means nothing except an exalted condition of the individuals composing it. All lawful care of self is therefore a form of public benefaction. Whatever diminution of mortality we enjoy from the diseases that formerly depopulated countries, is due rather to a higher civilization than to what is termed Sanitary Science. That at present is synonymous with cleanliness; and as nations emerge from barbarism into civilization, cleanliness assumes greater importance in its relation to individual happiness, comfort and longevity."

Dr. Fuqua's paper was a very excellent one, and deserves a publication in full. His propositions are so mutually dependent upon each other that no abstract can do justice to it, because the harmony of the reasoning is marred by breaking the continuity,

Dr. Wm. Cheatham, of Louisville, read a paper upon "Sympathetic Ophthalmia." He believes it to be produced through the sympathetic system of nerves, the result of continued irritation. Said the writer: "The symptoms of sympathetic irritation, which I contend always precedes inflammation, are slight temporary blurring of vision, fear of light, flashes of light, pupil fails to dilate and contract as normally, and easy fatigue of eyes from use."

"Mr. P., struck in the left eye with a nail six months before he came to see me. The nail made a large wound of the sclera in ciliary region. Four months after the injury, symptoms of sympathetic irritation set in, which was soon followed by plastic irido-cyclitis. When I first saw him vision of both eyes was zero. I advised removal of wounded eye, which was submitted to. By leeching, warm and cold cloths, iodide of potassium and mercurial inunction continued for four months, he returned home with vision enough in right eye to go any where he wished."

"Captain S. lost sight of left eye some years ago from inflammation. Cornea of left eye opaque, synechia posterior with cataract. Some months ago sight of right eye began to fail. When I saw him he could only distinguish daylight from darkness. Left eye was sensitive to neither light nor touch. After trying for a few days treatment with no change for the better, I enucleated left eye, fearing the trouble was sympathetic. He was put on the mercurial inunction. The inflammation of the right eye was plastic in character, and I feared it would go on to suppuration. Leeches

were applied to the temple, the room darkened, and rest in bed advised, and cold cloths applied. In eight or ten weeks he returned to his work with vision $\frac{2}{10}$.

"Mr. C. had choroiditis; left eye was treated by another oculist, who performed iridectomy. Irido-cyclitis followed with closure of pupil. Some weeks afterward a spot of choroiditis started in right eye in supra-temporal quadrant. This oculist advised iridectomy in this eye, with enucleation of the left, against which the patient kicked, and fell into my hands. I treated him for some months, getting vision $\frac{2}{10}$ right eye. He returned home, reporting to me only occasionally. Four months ago he returned with renewed symptoms of inflammation of the right eye, vision $\frac{3}{10}$, and neura-retinitis present. I advised enucleation of the left, to which he consented. In three days the neura-retinitis was greatly improved, and vision doubled. He has gone on improving slowly but steadily since."

"From these and similar cases the inference was drawn, that the advisers of early enucleation, or of enucleation of all eyes that are blind or of no service, because if sympathetic inflammation sets in all is lost, are sometimes mistaken, and for the following reasons: No one can tell at once whether or not a majority of the injured eyes will go blind; and in deciding this question it is important to decide whether this operation of enucleation is, as most physicians believe it to be, a harmless one. Graefe, Pagenstecher, Verneuil, Vignau, and others, report fatal cases. I myself have had severe hemorrhage to follow enucleation in two cases—in one case nearly fatal. In the young it often leads to deformity by contraction of the orbit; occasionally sympathetic ophthalmia is excited by enucleating the diseased eye; when the sympathetic ophthalmia is a serous iritis, the enucleation of the offending eye excites a plastic irido-cyclitis, with loss of the good eye. So it will be observed that enucleation is not entirely harmless. 'Is it proper to advise the enucleation of a hopelessly blind eye as long as the other is normal?'"

"During last winter a young man came to me from Clarksville, Tenn., having been shot in his right eye the day previous. The shot passed through cornea, iris, lens, vitreous humor, retina, choroid and sclera, and into the back of orbit. Of course the latter was not discovered until after enucleation. The young man was a farmer in medium circumstances. I made this statement to him: 'If you will stay here under my observation for some weeks, it is possible that I might save that eyeball for you, and even possible with some vision; there will be great loss of time and considerable expense. Notwithstanding the best treatment I can give you, it is possible that the eye may have to be removed anyhow; there are many chances for this, with some risk of its affecting the other eye and damaging it materially.' With this statement before him, he wisely decided to have it enucleated, when the previously detailed condition of things was found to exist."

"The question of preventative enucleation hinges on other important points besides the dangers of sympathetic ophthalmia: 1st, the ability of the patient to lose the time necessary for appropriate treatment; the nearness of a physician

who is able to recognize sympathetic irritation and enucleate the offending eye; and the intelligence of the patient."

The following conclusions closed the paper: "Enucleation is better performed in the stage of irritation. If it cannot be performed then, operate in the stage of inflammation, for while there is life in the eye there is hope. It should not be performed in iritis serosa. It can be performed at the onset of irido-cyclitis plastica, though the eye causing the sympathetic inflammation may not be blind."

The following resolution was adopted:

WHEREAS, The late Dr. Samuel D. Gross, of Philadelphia, was one of the earliest presidents of this society and always on its roll, it is fit that we should formally add our word of respect to his memory. What we shall say of him is much to us, though it is but a small part of the long sum of testimonies to his worth going up from medical men in both hemispheres. In recognizing his high merits we shall join company with the most dignified and venerable institutions of learning known to the English-speaking race, institutions that have done themselves honor in bestowing honors upon him. It is some comfort to us who mourn him that in the corporate existence of this organization of which he was a founder, *he still lives*. To our remotest year his name shall stand as that of one upon whose full and excellent life, every member may well wish his own were modeled.

Resolved, That as he was a great surgeon and leader of thought, we shall continue to hold his precepts in high esteem. As he was a kind and loyal friend, we shall cherish our memories of his personal dealings with us. As he lived frankly, purely and courteously, we shall reverence in him the gentleman above reproach.

J. W. HOLLAND,
WM. BAILEY,
J. H. LETCHER.

Dr. T. H. Stucky, of Louisville, read a paper on "Catarrhal Headache and Its Allied Affections." After entering into the anatomy and functions of the nose, he said: "In acute coryza we have besides the general lassitude, malaise, alternate chilliness and heat, and more or less weight and pressure about the frontal region especially. Examination in such cases will reveal a thickened œdematous nasal mucous membrane approaching nearly to occlusion, which, in proportion as it nears completeness, measures the frontal uneasiness. The membrane is at first dry; then stimulated secretion occurs, when some degree of ease is secured. The connection between the nasal cavity and frontal sinus is quite direct through the anterior ethmoidal cells and infundibulum. The varying size of the frontal sinuses measures to a large extent the discomfort arising from the extension of the inflammatory process from the nose. A case was cited to illustrate the connection between acute coryza and frontal pain."

Chronic catarrhal rhinitis was discussed by the writer, whose paper was not discussed.

Dr. J. M. Matthews, of Louisville, speaking on the subject of "Operations Upon Hemorrhoids During the Inflamed State," said: "I do not think that any physician or surgeon engaged in practice long will deny the frequency with which hemorrhoids occur among their clients, nor the inconvenience and suffering which it entails upon the subject of them. I was much interested in the remarks of Dr. Holland on the 'Cause of Consumption,' especially those remarks which related to the fact that the disease was unknown among them previous to the advent in their midst of the white man. It is a notorious fact, stated by Dr. Buren, that in his experience among the Indians he never saw one of them with hemorrhoids, and he examined hundreds of them. This

fact has a bearing upon this subject, as well as upon tuberculosis.

"I find in my dealings with this special class of patients that often the symptomatology of the affection is not quite understood. I do not mean to say there is not a physician who can diagnose a case of piles, but that there are quite a number who do not diagnose. I find that even the authors themselves differ as to the pathology of a pile. I take it that a pile is, in reality, a tumor, just as much so as a tumor in any other situation. If this be true, the fallacy of injecting hemorrhoids with an acid for their cure can be readily seen.

"Those persons who have advocated the injection of hemorrhoids have never limited the injection to any special kind of tumor. How is a pile formed? The simple passage of hard feces through the gut, in persons the subject of constipation, repeated at intervals, is sufficient to begin an irritation ending in plastic infiltration of the tissue, the final result of which is a pile.

"I take issue with one of the authorities who characterizes this tumor as a vascular tumor. I take it there is a confusion in this; he means that the tumor is well supplied with blood; in reality the vessel which feeds it can be felt at the top, pulsating with a beat almost equal to that of the radial artery.

"Now, if you will permit, I will say there are strictly three varieties of these tumors: 1. The capillary, where the small vessels push into the folds of the mucous membrane without any infiltration at all. That is one kind, and it is a dangerous kind, from the fact that the circulation is free and rapid. Being fed by an artery of considerable size, if ulceration takes place over it and perforates it, there is danger that the patient will bleed to death. I have seen a case die from this cause. If the chain of morbid phenomena be not here checked, and the inflammation is allowed to continue, it goes on to the formation of the second variety, the venous pile.

"I received a letter after I read a paper last year before this society, from a gentleman in the society, asking me if I was not mistaken as to the veins in the rectum having no valves. In speaking of this, I spoke of the circulation as being very slow and feeble. He took issue with me. The confusion in his mind arose from the fact of the blending of the portal and systemic circulation; it had not occurred to him that reference was had to the absence of valves in the superior hemorrhoidal veins. Some relief is afforded from this condition by blending with the middle and inferior hemorrhoidal. There is occasionally a blending, likewise, with the portal and systemic circulation, and therefore is it that obstruction in the liver causes one kind of piles. Other causes operate differently. It is my experience that piles may exist for weeks or years above the sphincter muscle, and the individual be unaware of their presence. This is a matter of considerable importance, when it is considered that these patients often come before examining boards for pensions or life insurance. They ask the question, 'Have you ever had piles?' and he answers 'No.' Then this individual is taken sick, and during this sickness it is discovered that he has piles, and it renders his policy invalid. Now, admitting their existence to have been determined,

can the necessity of an operation be disputed? I take issue with any man who will say he can cure this kind of pile or tumor by anything else than an operation.

"From a variety of causes piles are liable to become inflamed, and once inflamed they may easily become strangulated by passage below the sphincter; everything is aggravated in this condition, and it may take some weeks to quiet the trouble. It has occurred to me to ask myself the question, why not operate upon them and get rid of them at once? There is no authority that says 'Operate upon a pile during the inflamed state,' but they will tell you to apply treatment to reduce the inflammation. Now I want to state one or two cases. A few weeks ago I was called in consultation, to a distinguished lawyer who was in this condition. The family physician in attendance had tried in vain to quiet inflammatory action for two or three weeks. I found hanging down from the anus two solid tumors. I passed the knife around them and ligated them. I visited him the following morning, expecting to find him in some trouble. To my satisfaction, that man was out of the house in one week.

"Another case, a young man, had a mass of inflamed tissue hanging from him larger than my two fists. It would have taken several weeks to abate the inflammatory trouble, and I ligated the whole mass. I went to see him the next morning. I was told by the people at the house that he had rested well all night, and got up early in the morning and went out. They sent for him, but he could not be found. Three days later I received a postal from Cairo, Ill., saying he was that far on his way home and was all right. When he got home he wrote me that he was entirely well. Since then I have had I suppose five or six cases of similar character, in which the proceedings and results are similar. I have therefore come to conclude that instead of applying remedies to relieve the inflammatory trouble, they should be operated upon at once."

Medical Society of New Jersey.

(Concluded from page 787.)

Wednesday.—The Society was called to order by the President at 10 a. m.

The Special Committee on Education presented the following:

Resolved, That this Society approve and adopt the recommendations of the Special Committee on the curriculum of preparation to be required of persons contemplating the study of medicine in this State, as contained in the report presented at the last annual meeting of this Society.

That to carry out the recommendation of said report in regard to a censorship as therein contemplated, this Society is of opinion that two Boards of Censors be appointed by Standing Committee each year, consisting of five members of this Society, one for the northern and one for the southern part of the State, to whom should be presented for approval the credentials of all persons proposing the study of medicine, and in case of the insufficiency of such credentials, to examine the applicant in the branches of science and learning indicated in the report of the Committee.

That the Standing Committee prepare and report to the Society for its adoption such amendments of its By-Laws as are necessary to carry out this plan and recommendation of the Committee.

That the Corresponding Secretary communicate the action of this Society on this subject to the district medical societies in this State, with instructions to adopt such regulations as shall effectually secure the observance of the measure adopted by this Society in the several localities.

That the Corresponding Secretary communicate the action of this Society on this subject to the State Medical Societies of the several States of the Union, and respectfully request their coöperation with us in this effort to elevate the standing of medical education throughout the country.

The resolutions occasioned considerable discussion, in which Drs. E. M. Hunt, C. J. Kipp, Godfrey, Welch, B. A. Watson, Ridge, Benjamin, and English took an active part.

On motion of Dr. Benjamin they were adopted.

On motion of Dr. E. M. Hunt, the following resolution was adopted:

Resolved, That the Special Committee on Education be continued, and be requested to report next year to the Society what is feasible to be done to test the competency of graduates of various medical colleges who hereafter seek to settle in this State.

On motion of Dr. Hunt, it was

Resolved, That a committee of three be appointed by the President to report this afternoon what, in its judgment, can, or ought to be done by county medical societies, or by local officers, to prevent unlicensed persons who record imperfect licenses from practicing in this State.

The President appointed the following named gentlemen to constitute the committee: Drs. Parrish, Pennington, and Welch.

Dr. Garretson, in behalf of the Committee on Medical Jurisprudence, read its report, which, after considerable discussion, was, on motion, referred back to the Committee for amendments.

On motion of Dr. Hunt, the following was adopted:

Resolved, That this Society recognizes the importance of some legislation as to the modes of securing expert testimony.

Dr. B. A. Watson, Chairman of the Committee on Army Medical Museum and Library of Surgeon-General's Office, made a complete report, appended to which were the following:

WHEREAS, It is the opinion of the Medical Society of New Jersey that the Army Medical Museum and Library of the Surgeon-General's office, at Washington, D. C., have been largely instrumental in the advancement of sound professional and scientific knowledge, and that they give promise of still greater usefulness in the future. And

WHEREAS, It is learned with regret that both these collections are in great jeopardy from fire or accident through the insecurity and unsuitableness of the building in which they are stored; it is

Resolved, That Congress be respectfully urged to provide suitable, indestructible quarters for these invaluable treasures, to secure them against any possible contingency of loss or damage.

Resolved, That it is the sense of this meeting that the management of these national collections has been eminently successful in the past, and that any change of administration would not only be injurious to these interests, but would cast an undeserved stigma upon the office of the Surgeon-General of the army.

Resolved, That we again respectfully petition Congress to provide suitable annual appropriations for the increase and preservation of the Museum and Library, and also for carrying on the valuable "Index Catalogue" of the Surgeon-General's office.

Resolved, That a committee of three be appointed by the Chairman of this Society to prepare a suitable memorial, which shall be printed and sent to each of our representatives in Congress.

The President appointed Drs. B. A. Watson, H. G. Taylor, and E. M. Hunt, as the committee.

The report of the Committee on Lunacy was read by its chairman, Dr. Parrish, and the following resolutions, which were offered by the committee, were, on motion of Dr. Benjamin, adopted:

WHEREAS, The Legislature of the State of New Jersey, having, at its session of 1883, passed an act entitled "An Act to Create a Council of State Charities and Correction;" it is deemed of such importance to the health and well-being of the people as to call for congratulations by the Medical Society of New Jersey; therefore,

Resolved, That the Medical Society of New Jersey, in annual meeting assembled at Cape May, June 10 and 11, 1884, welcome the appointment by the Governor of the State of a Council of State Charities and Correction as an additional and co-operative factor with the Medical Society in correcting the neglects and abuses to which the insane poor of the State are subjected, especially in the county almshouses throughout the State.

Resolved, That in congratulating the community upon the existence of such a council, the Medical Society of the State, the district societies in the different counties, and individual physicians in their respective homes, will cheerfully co-operate with said Council in all suitable and legitimate plans to secure the result contemplated by law.

Resolved, That the corresponding secretary be instructed to transmit to said Council a copy of these resolutions, with a copy also of the *Transactions* of this annual meeting when they shall be published.

Dr. C. J. Kipp then read an essay on the "Prevention and Treatment of Purulent Conjunctivitis." He believes this disease is always due to inoculation, and may be prevented by the employment of prophylactic measures. He thinks there is reason to believe that the disease is frequently induced by inoculation of the conjunctiva by leucorrhœal fluid during parturition, and therefore it might often be prevented by repeated injections of tepid water into the vagina during the first stages of parturition. In the treatment of the disease, he recommends cleanliness, application of cold to the lids in the early stage, and the application of a solution of nitrate of silver later on. Prefers absorbent cotton to sponge in wiping away discharges. The eyes should be opened and cleaned at least every hour.

Dr. Geo. T. Welch, of Keyport, followed with

an essay on, "Many Drugs: Few Remedies." He said:

"The modern physician in his multitudinous drugs finds few remedies. The average of human life is greater, but commerce and the arts have given greater comfort, better food, new thoughts, wider horizons, and none of the sciences can claim too great a share in the world's advancement. Medicine finds its highest achievements in the prevention, not in the cure of disease. Cancer shows a steady relative increase in England: in New Jersey the average death-rate from this disease is 1 in 54 of all the deaths that occur. Malarial diseases spread in wider circles. Does not the ravage of tuberculosis go on? Who has won eminence in curing yellow fever? The exanthemata sweep into and out of every neighborhood about once in five years. Who cures rheumatism, or typhoid fever, or chronic Bright's disease? Who never recoiled before a patient simmering in the horrible slow flame of pyæmia? And yet who refrains from prescribing? The journals teem with fortunate prescriptions, the nostrums of manufacturing chemists push braggart charlatanism to the wall. No monstrosity of theirs so impudent that a dozen college professors will not laud the mixture. This was once the province of the clergy, but we do things differently now.

"The decadence of drugs once high in esteem, and the discovery of the parasitic cause of many diseases, should make us skeptical of medicines and their applications, rather than enthusiastic in heralding the new. But a large body of medical men lend themselves to this insanity, and the commercial class keeps up the hue and cry, out of no philanthropy, but to fatten on the weakness of the profession, and the misfortunes of the race.

"The young doctor believes in the magic of drugs, the old doctor regards the majority of them as mischievous, while the pathologist suspects them all. We hear of the so-called cures, but rarely do we hear of the failures. Truth can never be arrived at until both sides are known. As to the drugs, most of them are poisons. Solutions of the majority of them destroy plants, and corrode the vital organs of animals. The test of new drugs upon animals, and the argument from these to man, is in many instances highly fallacious. Such drugs as morphia and atropia have slender effects on birds and herbivorous animals, while many others have frequently toxic effects, without corresponding symptoms in man. As, for instance, citric and tartaric acids, camphor, cocculus, dulcimara, and liq. ammon. acet., poison fatally in their order cats, rabbits, dogs, and fish. Some drugs act differently upon different animals, as colocynth, which has feeble action on horses, sheep, and swine, while it purges dogs and rabbits violently; cyclamen poisons fish, while pigs can eat any quantity of the root; hyoseyamus is eaten without harm by hogs, and does not injure sheep or cows, while upon dogs it has much the same effect as upon man.

"The only way to arrive at the average merit of new drugs, or the old, is to record the results of their application in the same classes of disease, under the varying conditions of hygienic surroundings over vast areas. But this is not practicable, for the majority of physicians are plodders, followers, men of routine. One other means

presents itself, colléges of experimental medicine, conducted under the eyes of the State, or the supervision of the highest medical authorities. Here should be rigorous system, exact registration, frequent comparison and correction. At the same time we must recollect, for all our attainments, that but comparatively little is known of the natural history of diseases. The tendency of nature to remedy ills without interference would astound the medical world could it be known aright. Hundreds of diseases would end in recovery if never a drug were given. We deceive ourselves with cures. The last drug gets the credit, where none deserves it. On the other hand, many diseases have continued to be incurable for ages, though even the wisest physician would probably feel himself criminal not to prescribe something. And given one thing, to give another is a natural sequence.

"Even to give an ample margin, after twenty-five leading medicines, as iron, iodine, quinine, strychnine, brandy, and opium, have been selected from the mass of drugs persistently thrust upon the profession, the rest might be 'in the flat sea sunk,' and the death-rate be no greater."

Drs. Thomas A. Emmett and Isaac Taylor, of New York, having been duly recommended by the committee, were unanimously elected honorary members of this Society.

It was voted that the Business Committee of last year be continued.

The Committee on Honorary Membership was also continued.

Drs. O'Hara and W. B. Ulrich, delegates from the Medical Society of Pennsylvania, made brief and appropriate responses to their formal presentation.

A petition from the physicians of Cape May, asking for a commission to organize a medical society in that county, was received, and, on motion, it was ordered that the commission be granted.

Drs. Wickes, W. P. Watson, and E. M. Hunt, are the Committee on Fellows' Prize Essay. The Committee were instructed to select a subject for the essay, and publish the same in the medical press.

The following officers were elected for 1884:

President.—P. C. Barker.

First Vice-President.—Jos. Parrish.

Second Vice-President.—C. J. Kipp.

Third Vice-President.—J. W. Ward.

Recording Secretary.—Wm. Pierson, Orange.

Corresponding Secretary.—Wm. Elmer, Trenton.

Treasurer.—W. W. L. Phillips, Trenton.

Standing Committee.—T. J. Smith, E. J. Marsh, D. C. English.

DELEGATES.

American Medical Association—J. H. Pugh, J. W. Snowden, I. H. Love, Wm. Pierson, W. P. Watson, H. C. Clark, Wm. Elmer, D. B. Ingersoll, D. C. English, J. E. Avison, A. W. Rogers, I. Gibbon, W. H. Merrill, J. W. Paul, J. M. Beam.

Pennsylvania Medical Society—T. R. Varick, Joseph Parrish, E. Busby.

Connecticut Medical Society—N. Williamson, H. G. Buckingham, C. R. Wiley.

Rhode Island Medical Society—H. H. James, E. H. Reily, M. Abel.

Massachusetts Medical Society—E. W. Hunt, H. M. Weeks, P. A. Harris.

Maine Medical Society—J. H. Griffith, E. Worth, J. L. Bodine.

Vermont Medical Society—D. M. Forman, P. Hoffman, D. Benjamin.

Delaware Medical Society—G. T. Welch, W. H. Amos, E. Oliphant.

New York Medical Society—J. S. Green, D. B. Ingersoll, J. S. Whitaker.

British Medical Association and International Medical College—E. M. Hunt, J. N. Quimby, S. S. Clark.

It was voted that the next annual meeting of this society be held at Long Branch, on the second Tuesday in June, 1885.

Dr. H. H. James was appointed essayist for the next meeting.

It was voted that the assessment next year be one dollar and a half per capita.

The President appointed the following Committee of Arrangements for the next annual meeting: S. H. Hunt, H. R. Baldwin, D. M. Forman, W. H. Shippis, Henry Mitchell.

On motion of Dr. Godfrey, the following was adopted:

Resolved, That a vote of thanks be extended to the officers of the West Jersey R. R. Co., to Mr. McClellen, the proprietor of the Stockton Hotel, the mayor and citizens of Cape May, for their generous hospitality and courtesy to the members of this society, and to Committee of Arrangements.

Resolved, That the Corresponding Secretary be instructed to inform them of the passage of this resolution.

Adjourned.

Buddhism and the Transmission of Diseases.

The Buddhist law is significantly stringent on this point—so much so that, according to Jardine's translations of the Burman's law of "Marriage and Divorce," we observe that, should man or woman unwittingly marry into a family afflicted with certain hereditary diseases, as leprosy, cancer, syphilis, madness, etc., which in the Dhammathat relating to marriage are collectively designated "*hinaroga*, or wasting diseases," he or she may sue out a divorce. Buddhists are taught to believe that not only will the children of diseased parents inherit a transmissible disease, but that the husband or wife will contract the same by association—living together under the same roof.

Personal.

—Dr. Carl Seiler, of this city, will be the efficient resident physician at the "Mountain House," Cresson Springs, this summer.

MARRIAGES.

GARRETSON—ZELLER.—At the residence of the bride's mother, on Tuesday evening, June 10, 1884, Dr. Will M. Garretson and Miss Maggie Zeller, both of Perkinsville, Ind.

PRATT—JACKSON.—At Bellefontaine, Logan county, Ohio, June 5, 1884, by Rev. Newton, Dr. Lester C. Pratt and Miss Sallie M. Jackson.

INDEX.

- Abdomen, suppurating hydatid of, 276.
 Abdominal; surgery, cleanliness in, 136; tumor, 238; aneurism, 422, 453.
 Abort mammary abscesses, 119.
 Abortion; septicæmia after, 110; active interference in, 599.
 Abscess; mammary, 13; cervical incision in, 27; lumbar, 212; of kidney, 699.
 Abscess; of lung, 719; hepatic, 753.
 Abscesses; mammary, to abort, 119; psoas, method of opening, 145; multiple hepatic in, 537.
 Absorptive power of skin, 408.
 Acetal paraldehyde, 91.
 Acetonæmia and diabetic coma, 440.
 Acid; pipitzaholic, 19; carbolic, poisoning, 51; carbolic, use of, 285; salicylic, 26, 48, 60, 219, 313, 410, 411, 701; in cerebro-spinal meningitis, 313, 701; carbonic, in whooping-cough, 221; phenic, in yellow fever, 316; hypersomic, for neuralgia, 379; gallic, in hemorrhage from, 535.
 Aconite, poisoning by, 473.
 Action and reaction, 470.
 Actinomycosis, case of, 303.
 Acute; Bright's disease, globulinuria in, 18; osteo-myelitis, 27; pyæmia, 57, 345; sore throat, 69; nephritis, treatment of, 24; meningitis, 391, 424; treatment of, 17; aortitis, 347; rheumatism, 505; sudden dislocations during, 314; lobar pneumonia, 551; pulmonary tuberculosis, 552; general peritonitis, 552.
 Adenitis, chronic treatment of, 475.
 Adenomatous growth, 142.
 Administration; of quinine, 26; of salicylic acid, 48; medicine, unobjectionable form of, 388.
 Adulterated butter and cheese in New York, 672.
 Adulterations, 191; of mustard, 599.
 Advantage of koumiss, 95.
 Affection, retinal, 5.
 Affections of mouth, chromic acid in, 24.
 After-pains, gelsemium for, 58.
 Air-passages, creasote in diseases of, 243.
 Albumen, salt test for, 59.
 Albumen in urine, determination of, 747; new test for, 754.
 Albuminate of iron, 59.
 Albuminous urine in children, 58.
 Albuminuria; and phthisis, 120; nitro-glycerine in, 150; perspiration in, 185; unsuspected, 251; *vs.* Bright's disease, 404; treatment of, 458; puerperal, 483; transfusion of blood in, 593; in zymotic diseases, 697.
 Alcohol; in trichinosis, 60; *vs.* strychnia, 185.
 Alcoholic; leg-pains; 377; tremor, cure by verat-
 ria, 694.
 Alcoholism; cirrhosis without, 59; statistics of 279.
 Alcoholism, studies on, 754.
 Alumen, Ustum in, 776.
 Amenorrhœa and vicarious menstruation, 369.
 American medical literature, 30; salt pork, 159; pork in France, 224.
 Amniontome, 91.
 Amnii, hydrops, change in presentation, 503.
 Amputation of penis, 406.
 Amputations, high, for, 49.
 Amyl, nitrite, in pneumonia, 315.
 Anæmia; chronic, 59; iron, hypodermically, in, 154.
 Anæsthetic; mixture, 15; sulphuric ether an, 220; action of ether spray, 315; ether *vs.* chloroform an, 315.
 Anatomy; metrical, of eyes and orbits, 253; of hymen, 688.
 Anæsthetics, administration of, 286.
 Aneurism; arterio-venous, 56; of aorta, 27; of basilar artery, 92; atheroma, 205; abdominal, 422, 453; pressure on pons by, 775.
 Aneurisms, miliary, of stomach, 537.
 Ankle-joint, disease of, 520.
 Anodyne; menthol cone, an, 170; mixture with-
 out opium, 506.
 Anterior columns excitable? 776.
 Anthelmintics, hypodermic injection of, 698.
 Anthropology, criminal, prize essay, 383.
 Anti-vivisection, 217; anti-vivisection in Ger-
 many, 383; galactagogue, iodide of potassium an, 218.
 Antiseptic; inhalations in phthisis, 183; dress-
 ing, 175; application of, 530; inhalation, 304.
 Antiseptics, tubercle, resistance to, 242.
 Antipyretic treatment of typhoid fever, 439.
 Antipyretic treatment, method of, 752.
 Anuria from compression of ureters, 370.
 Aorta; atheroma aneurism of, 205; aneurism of, 271; puncture of, 406; rupture of, 441.
 Aortic valve disease, 140.
 Aortitis, acute, 347.
 Apomorphia, new use for, 28.
 Appendages, uterine, 14.
 Appliance for symphyseal fracture of lower jaw, 529.
 Pyrexia, absorption of fat in, 48.
 Arlentin, medicinal properties of, 121.
 Arrested phthisis, 92.
 Arsenic, bromide, in diabetes, 27.
 Arterio-venous aneurism, 56.
 Arthritis, chronic, of shoulder-joint, 579.
 Artificial; urea, 59; food for children, 408; cou-
 marin, 443.
 Asbury Park and Ocean Grove, 540.
 Ascarides, treatment of, 701.
 Assimilation of food, influence of bile in, 339.
 Asthma; lobelia inflata in, 281; inhalation for, 347.
 Astigmatism, 77.
 Astounding medical legislation, 341.
 Asylums, detention in, 171.
 Ataxia; locomotor, 570; nerve-stretching in, 218.
 Athetosis, case of, 538.
 Atmosphere on voice, 152.
 Atony of the bladder, 423.

- Atrophy, cortical, researches on, 750.
 Atrophic nasal catarrh, 481.
 Attenuation, Pasteur's new method of, 61.
 Auscultation of œsophagus, 496.
 Automatism, post-epileptic, 440.
 Autopsy of transverse colon, 75.
- Bacilli; in sputum, 65; tubercle, tenacity of, 697.
 Bacillus; tubercle, 62, 313; tuberculosis, 364, 394, 427, 433.
 Back-ache, sacrahe and, 377.
 Bahama Islands for consumptives, 319.
 Basilar artery, diagnosis of, 92.
 Bath, the warm, 60.
 Bathing, glycerine after, 314.
 Battery solution, 8, 93.
 Battey's operation, 110.
 Bed-sores, hypericum for, 152.
 Beer-drinking, 190.
 Belladonna plasters, caution about, 154.
 Berlin polyclinic, 287.
 Bert on chloroformization, 380.
 Biceps muscle, supposed dislocation of, 530.
 Bichloride of mercury, 89, 695.
 Bigelow's operation, crushing by, 361.
 Bile, influence of, in assimilation of food, 339.
 Bitch, milk of, 60.
 Bladder; gall, cancer of, 240; atony of, 423; foreign body in, 473; rupture of, 531.
 Bleeding in delirium tremens, 434.
 Blindness; and syphilis, 147; cause of, 221; simulation of, 700.
 Blistering; in diphtheria, 91; humane, 282; topical cardiac in acute rheumatism, 505.
 Blisters over the heart, 59.
 Blood; tears of, 18; desiccated, 102; letting in the young and old, 129, 261, 291; *vs.* morphia in, 411; a specialty, 574; disorganization of, 271; transfusion in, 593; time required for, 679.
 Boils, treatment of, 83.
 Bone, neuralgia of, 304.
 Bovinus sanguis, 102.
 Bower and Keates case, 182.
 Bowel; ulceration of, 501; membranous cast of, 698.
 Brain; exhaustion, 146; abscess, 204; in children, inflammation of, 281; influence on mental faculties, 346; and cranium, Cuvier's, 537.
 Breast; sarcoma of, 46; bony tumor of, 88; removal by thermo-cautery, 138.
 Bright's disease, 139; globulinuria in, 18; ear affections in, 60; diet in, 177; treatment of, 401, 598; albuminuria, 404; jaborandi in, 442; diagnostic value of severe coryza in, 494.
 Bromethyl in childbirth, 184.
 Bromide of arsenic in diabetes, 27; ethyl in, 209, 280.
 Bromine in diphtheria, 474.
 Bronchial glands, 492.
 Bronchitis of rheumatic origin, 671.
 Bryonia dioica, poisoning by, 120.
 Buddhism and the Transmission of Diseases, 800.
 Bunions, new cure for, 57.
 Burn Bra private asylum, 511.
 Burns and scalds, 682, 696.
 Caffeine, 176.
 Calcification of pleura costalis, 380.
 Calcified pericardium, 108.
 Calcium sulphide in diabetes mellitus, 505.
 Calculi; salivary, of, 177; of pancreas, 496.
 Calculus; renal, 141, 506; vesical, 361; urinary, an enormous, 699.
 Calomel, hypodermatic injections of, 463; large doses in, 772.
 Camphor in mixtures, 59.
 Canadensis, hydrastis, 283.
 Cancer; progress of, 24; mammary, treatment of, 151; internal, sign of, 154; of rectum, 282.
 Cancerous womb, 14; disease, anuria from compression of ureters by, 370.
 Cannabinum tannicum, 91.
 Capital punishment, 566; in Delaware, 703.
 Capitis eczema, 538.
 Carbolic acid poisoning, 51; use of, 285.
 Carbonic acid in whooping cough, 221.
 Carbuncles, treatment of, 83.
 Carcinoma of uterus, 207.
 Carcinomatous sarcoma, 45.
 Cardiac poisons, new, 568; palpitation, 768.
 Caries, spinal, operation in, 593.
 Carelessness or ignorance, 721.
 Case of carcinomatous sarcoma, 45; chronic dysentery, 45; chromidrosis, 82; epididymitis, 82; gall stones, 134; scarlatina, 161; pyæmia, 167; phthisis with empyema, 204; trismus nascentium, 232; gangrene, 274; actinomycosis, 303; scorbutus, 513; Graves' disease, 513; atelectosis, 538; nervous disease, 789.
 Casein in human milk, 193, 225.
 Castration for uterine fibroids, 303.
 Catarrh; vesical, salicylic acid for, 60; of epithelial cells, 89; nasal, in children, 228, 259; nasal stenosis, cause of, 249; inhalation for, 347; atrophic, nasal, 481.
 Cataract, modern operations for, 380.
 Catarrhal jaundice, 609.
 Catheter fever, 174.
 Catheterization of infants, 92.
 Causation of sex, 627.
 Cause of dyspepsia, 57.
 Caustic, a ready, 315.
 Cauterization of lung, 25.
 Cantharides, tincture of, 443.
 Cellulitis, pelvic, 50.
 Cephalalgia, syphilitic, 27.
 Cerebral syphilis, 21-28; clinical aspects of, 620; embolism, fatal, 264.
 Cerebro-spinal meningitis, salicylic acid in, 313, 410, 411, 701.
 Cerebro-spinal meningitis, 723.
 Cervical; abscess, incision in, 27; portion of spinal cord, inflammation of, 460.
 Cervix uteri; epithelioma of, 114; rigidity of, 232, 419.
 Cervix, laceration of, 741.
 Chancreoid; treatment of, 545; and syphilis, 557, 567.

 Tremens; delirium, 289, 321; complicated with, 206; delirium, bleeding in, 434.
 Tremor, alcoholic, cure by veratria, 694.
 Tribute to late Prof. S. D. Gross, 787.
 Trichinosis, 184; alcohol in, 60; cases of, 283.
 Trichlorphenol in, 50.
 Trismus nascentium, 232.
 Typhilitis, treatment of, 623.
 Typhoid fever; extractum pancreatis in, 182; ulcer, sore throat, 282; treatment of, 397; acute meningitis in, 391, 424; complicated by nephritis, 408; antipyretic treatment of, 439; contagiousness of, 538.
 Typhus fever, micro-organisms in, 90.
 Typical neurotic, 686.
 Tubercle; bacillus, 62, 313; inoculation of, 92; resistance to antiseptics, 242; of iris, 571; bacilli, tenacity of, 697.
 Tubercular growths, 110; peri-urethritis, 345; meningitis, 391, 424, 464; disease of thumb, 748.
 Tuberculosis, 702; in childhood, 50; spontaneously curable? 89; conveyed by food, 93; of testes, 344; bacillus, 364, 394, 427, 433; pulmonary treatment of, 431; inoculation of, 473; acute pulmonary, 552; of iris, 572.
 Tumor; bony, of breast, 88; of sciatic nerve, 142; congenital, fatty, 142; odonto-periosteal, 199; abdominal, 238.
 Tumors; gummatous, in muscles, 90; encysted, destruction of, 264.
 Turpentine, prophylactic, in infectious diseases, 407.
 Turpeth mineral, poisoning by, 93.
 Ulcer, perforating in child, 687.
 Ulcerated larynx, 363.
 Ulceration of bowel, 501.
 Ulcerations, multiple, cutaneous, 528.
 Ulcers, dressing for, 91.
 Ulcerous typhoid sore throat, 282.
 Umbilical; cord, fatal traction on, 221; hernia, noteworthy, 505.
 Umbilici, fungus, resorcin in, 58.
 Unguentum hydrargyri ammoniati, 91.
 Urea; artificial substitute for, 59; discovery of, 309.
 Ureters; occlusion of, 56; anuria from compression of, 370.
 Urethra; excision of, 58; opening into vagina, 275; transplantation of, 406.
 Urethral; origin, acute pyæmia of, 345; fever, malarious disorders on, 368.
 Urinary; examinations, 250; organs, gallic acid in hemorrhage from, 535; calculus, an enormous, 699.
 Urine; albuminous, in children, 58; organic phosphorus in, 401; tincture of cantharides for, 443; prostatic retention of, 747; albuminuria in, 747.
 Uteri; cervix, 114; rigidity of, 232.
 Uterine; appendages, 14; reflex vomiting, 208; fibroids, castration for, 303; disease, 382, 739; displacements, 536; affections, salicylate of sodium in, 754; extra-, gestation, 687.
 Uterus; carcinoma of, 207; spasmodic contrac-

- tion of, 472; partial inversion of, 753; persistent flaccidity of, 502; epithelioma of, 584; hour-glass contraction of, 624.
- Vaccination, argument for, 441.
- Vaccine, pulverized, 219.
- Vagina; urethra opening into, 275; post-partum prolapse of, 504.
- Vaginal cicatrix, dystocia due to, 27.
- Varicella nephritis, 700.
- Varicose veins, treatment of, 251.
- Venereal disease, benignity of, 184.
- Venesection, plea for, 443.
- Venous, arterio-, aneurism, 56.
- Veratria; *vs.* lancet in pneumonia, 549; cure of alcoholic tremor by, 694.
- Vertebrated catheter removed from, 104.
- Vesical; catarrh, salicylic acid for, 60; calculus, 361.
- Vesico-vaginal fistula, 598, 739.
- Veterinary department of University of Pennsylvania, 222.
- Vicarious; menstruation, 369; hemorrhage from one mamma, 699.
- Viscera, neuroses of, 500.
- Visceral lesions with epileptiform, 371.
- Vision, disturbance of, 699.
- Vivisection, 630; anti-, 217; practice of, 284; question, 375; anti- in Germany, 383; law, 437; anti-, defeat, 606.
- Vivisectionists, anti-, 94.
- Voice, effect of atmosphere on, 152.
- Vomiting; reflex, nutrient enemata in, 121; uterine, 208; pregnancy, 283, 757.
- Voyaging, sea, 378.
- Vulva, dilatation of, 313.
- Warm; bath, 60; foot-bath, 284.
- Water; supply, our future, 22; limiting our, 470; dressings for wounds, 220.
- Whisky, thrown in eyes, severe conjunctivitis from, 539.
- Whooping-cough; carbonic acid in, 221; chestnut leaves in, 442; croton-chloral hydrate in, 475; treatment of, 752.
- Winking, spasmodic, 283.
- Women; wise, of Serbia, 62; in medicine, 148; doctors, the question of, 181; doctors, 285; place in nature, 380; physicians in Asia, 616, 649, 673; are dirty creatures anyhow, 693.
- Worms; parasite, 56; intestinal, 220; flesh, 380.
